Dr. JOHN CHARLES HESSLER has been appointed assistant director of the Mellon Institute of Industrial Research of the University of Pittsburgh, by Director Raymond F. Bacon. Dr. Hessler, who is now serving as president of the James Milliken University, Decatur, Ill., will enter upon his new duties at the close of the present academic year. As a member of the administrative staff of the Mellon Institute, Dr. Hessler will be in supervisory charge of certain of the researches in organic chemistry, a field in which he has specialized during the past twenty years.

G. M. HUNT, of the wood preservation section of the Forest Products Laboratory, recently gave a lecture before the Western Society of Engineers, Chicago, on the relation of the Forest Products Laboratory to the engineering profession.

Dr. DAVID KLEIN has resigned his commission as Major in the Sanitary Corps, U. S. Army, and accepted a position with Wilson & Co., Chicago, Ill.

DONALD M. LIDDELL, who has been on a professional trip in the West, has returned to New York.

JOHN L. MALM, metallurgical engineer, of Denver, Col., has been in New York on professional business.

ROBERT B. MILLER has entered upon his duties as state forester at the University of Illinois, Urbana, Ill.

R. B. RUDY, formerly consulting engineer with the Nitrate Division, Ordnance Department, has accepted a position with the Air Reduction Co., Inc., 120 Broadway, New York City.

FRANK L. SILSBEE, secretary of the National Association for the Protection of American Rights in Mexico, with headquarters in New York City, has been elected vice-president of the Federal Petroleum Co., with headquarters at Shreveport, La. He will have charge of the operations of that company in the Louisiana territory.

H. G. THIELE, formerly with the Oliver Continuous Filter Co., has accepted the position of superintendent in charge of the Boro Solvay potash plant of the Solvay Process Co., at Searles Lake, Cal.

FRED H. WAGNER has just returned from an extended trip in Europe, where he has been in the service of the Bartlett-Hayward Co., Baltimore, Md.

A. E. WHEELER has arrived in New York City after about a year's absence in England and the Belgian Congo, on work in connection with the new concentrating plant for Union Miniere du Haut Katanga.

B. B. THAYER, WILLIAM WRAITH and W. C. CAPRON expect to return early in April from Chile, where they have been inspecting the developments at the Andes mine and leaching plant.

Dr. WILLIS R. WHITNEY is to be the recipient of the Chandler medal as a recognition of his achievements in science. Dr. Whitney's subject will be "The Littlest Things of Chemistry." His lecture will be in Havemeyer Hall, Columbia University, New York City, the evening of April 27, 1920.

Obituary

ZEAR J. CHAMBERLAIN, of the Ludlow-Saylor Wire Co., St. Louis, Mo., died suddenly on March 20, in his forty-fifth year. He had been with this company since he was seventeen years old.

DIRK GEIJSBEEK MOLENAAR, of the Geijsbeek Engineering Co., Portland, Ore., died on March 11.

MELVIN B. NEWCOMB, aged thirty-one years, chief engineer of the rubber machinery department of the Wellman-Seaver-Morgan Co., died on Sunday, March 13, after a short illness, at his home, 742 West Ave., Akron, Ohio.

Current Market Reports

The Non-Ferrous Metal Market

New York, March 29, 1920.—The market remains quiet, with quotations as follows:

	Cents per Lb.
Copper, electrolytic	18.75
Aluminum, 98 to 99 per cent	31@32
Antimony, wholesale lots	11.00
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	61.50
Lead, New York, spot	9.00
Lead, E. St. Louis, spot	8.75
Zinc, spot, New York	8.75
Zinc, spot, E. St. Louis	8.50

OTHER METALS

Silver	oz.	$1.23½
Cadmium	lb.	1.40@1.50
Bismuth, (500 lb. lots)	lb.	2.50
Cobalt	lb.	1.50
Magnesium (f.o.b.) Niagara Falls)	lb.	1.60
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00
Mercury	75 lb.	95.00

FINISHED METAL PRODUCTS	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	26.75
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	32.00
Seamless bronze tubing	34.50
Seamless high brass tubing	33.00

SCRAP METALS	Cents per Lb. Buying Price
Aluminum, cast scrap	22½@23½
Aluminum, sheet scrap	22 @22¾
Aluminum clippings	25½@26½
Copper, heavy machinery comp	15 @15½
Copper, heavy and wire	13½@14¼
Copper, light and bottoms	12 @12½
Copper, heavy cut and crucible	15 @15½
Brass, heavy	7 @7¾
Brass, casting	10 @10½
Brass, light	5⅞@6¾
No. 1 clean brass turnings	7⅜@7¾
No. 1 comp. turnings	11¼@11½
Lead, tea	5½@5¾
Lead, heavy	7 @7½
Zinc, scrap	4¼@4½

The Iron and Steel Market

Pittsburgh, Pa., March 26, 1920.

The iron and steel markets in the past week have been rather bare of the new developments that have been making the weeks interesting for a long time past. Without there being clear-cut developments, however, there have been distinctly marked trends of importance. One of these is the great dwindling in the volume of prompt business, together with a tendency of delivery premiums to decrease. Another is the growing indisposition of buyers

to commit themselves for forward deliveries. In pig iron there has been a very quiet market, but that is not a particularly fresh item. In spots a little softening in pig-iron prices is noticed, but on the other hand prices seem to hold up moderately well for such a quiet market.

Delivery Premiums

With a calm view of the whole market situation, one can hardly avoid the conclusion that the basis of the market is the Industrial Board prices which became effective March 21, 1919, and to which the United States Steel Corporation shows fully as strong adherence as at any time. A corollary is that all other and higher prices are premium prices, the premium being paid by reason of the earlier delivery involved as compared with the delivery the Steel Corporation could make, or by reason of the buyer not having an allotment by the Steel Corporation sufficient to cover his needs fully. For quite a while there was ground for a view that possibly there were two markets, Steel Corporation and independent, so that eventually one would have to meet the other. Such a view is certainly not tenable now. At any price above the Steel Corporation price one cannot sell far ahead.

The maximum range of delivery premiums has moved downward. The highest mill price obtained in the past few days for sheets has hardly been above 7c., when 10c. was done in a few instances late in February. The maximum on plates is now 4c., when 4.50c. was being obtained in not a few instances two or three weeks ago. The decline is not due to heavier offerings but rather to lighter market demand, this being due in turn to heavier receipts by consumers against purchases previously made.

As to prices of large independent producers who regularly sell some distance ahead, several of these producers are now committed to a definite policy of selling quarter by quarter, having a formal opening of books and naming prices just after the opening of one quarter for delivery in the succeeding quarter. Some sales are made in advance, however, perhaps at special prices, while next week or shortly thereafter there may be formal opening of books to all regular customers. Prices will not be above 3c. for bars, 3.10c. for shapes and 3.25c. for plates, and they may be lower, so that the market as to business of this description cannot be said to be advancing.

As to Steel Corporation prices, the only item this week is that sales of nails are again being made at the flat base price of $3.25. For a short time the corporation had been booking nails with the price item left open, the price to be the corporation price at time of shipment. This had led to an expectation that the corporation might make an exception of nails and announce a definite advance. There is a loss in nails, i.e., the profit is less in selling nails at $3.25 than in selling the plain wire at 3c., the corporation price.

Production

Production of pig iron and steel has increased slightly, but is still under restriction by car shortage, limiting the movement of Connellsville coke and of coal to byproduct ovens, as well as of fuel coal to steel plants. By announcement of the President, price restrictions on coal and coke are lifted, effective April 1. Then there will be an open market, with higher prices than the Government limits. This will not of itself increase the total supplies of coal, but it will enable the steel industry to bid for coal, and as its ability and willingness to pay higher prices, for the purpose of securing full production, are virtually unlimited the supplies will be obtained, probably insuring a large increase in byproduct coke production and a full operation of steel mills in the near future.

Pig Iron Dull

There are fewer offerings of small prompt lots of pig iron in the local market, but there are still sufficient offerings to meet the limited demand. Consumers are but little interested in early deliveries, and in second half deliveries they are not interested at all. Consumers of pig iron are evidently covered ahead to the extent that they have sold their finished products, whether iron castings, steel castings or rolled steel; and as their finished products are not selling with much freedom at present, there is no occasion for extensive purchases of pig iron to be made. As to steel-making pig iron, it is quite plain that there is no promise now of steel mills being able to sell finished steel products for second half delivery that would justify the payment of prices now asked for basic or bessemer iron. Pig iron, in its spectacular advance, was unable to force the steel market up sufficiently to make a harmonious relation. The market is quotable, largely nominal, at about $42 for bessemer, $41.50 for basic and $42 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.40.

Ferro-Alloys

Spiegeleisen is quiet at $57@$60. Ferromanganese is firm at the recently advanced price, $180, delivered, being minimum for second half, with some producers talking of $200. Prompt has sold at well above $200, but only in small lots. Ferrosilicon is quotable at $80@$81, delivered, for 50 per cent and $140 for 75 per cent. Bessemer ferrosilicon is $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. furnaces at Jackson and New Straitsville, Ohio.

Chemical and Allied Industrial Markets

New York, March 27, 1920.

The overtaxed chemical market has been firmer, if anything, during the past week than it was in the previous report. Supplies are not being replenished by producers at a rate sufficient to meet the demand and spot material on practically all items is nominal. Price advances during the week have been brought about mainly by the decreasing amount of supplies being received from producers, who are sold up from two to four months ahead on the main items on the list. The shortage of steel drums and containers has further hindered shipment from the producer to the consumer.

General Chemicals

Under the pressure of heavy foreign demand *aluminum sulphate,* commercial, advanced to 2½@3½c. per lb. with supplies on hand very light. Iron free has remained firm at 2¾@3¾c. per lb. Supplies on both grades of *sal ammoniac* are very scarce and the spot market is practically nominal, with white quoted at 15@18c. per lb., while gray is listed from 13@14½c. per lb. The stocks of English material in this market are now practically exhausted and a still further advance by domestic manufacturers is looked for. *Barium chloride* is firmer than at the time of the last report. Sales have been reported as high as $155@$160 per ton, but this is not to be taken as market price, as consumers under pressure of necessity will pay most any price. Manufacturers are sold ahead so far that relief is not expected before the end of the summer. *Calcium hypochlorite* remains steady, ranging from $3.50@$4.50 per cwt., according to the amount. A rise on this item is looked for in some quarters, owing to shortening of supplies being received from producers. Prices on *carbon bisulphide* have been advanced from 6c. as low mark on car lots to 7@8c. per lb. Quotations on *nickel salt* are practically nominal, as there is very little material to be had, 16@17½c. for the single and 14@15c. per lb. for the double.

Caustic potash is very scarce and at present the spot market is exhausted of supplies. Prices range from 25@28c. on car lots, according to quality, while dealers are asking from 30@35c. per lb. for spot with very little material to be found. *Soda ash* is in the control of the dealers, as they are the only ones who have any material to offer. Sales on the light have been reported as high as $3.50 per cwt. *Sodium nitrite* is somewhat easier than it was last week, spot material being offered at 35@45c. per lb., but the acute shortage of two weeks ago is not relieved and it will be some time before this item is back to normal.

Coal-Tar Products

General conditions remain unchanged, with the spot market tighter in supplies and firmer in price. Producers are not able to cope with the demand. Many of the items on

the list are nominal, as there is no material to be had at the prices quoted. One large factor in *naphthalene* has withdrawn from this market, as he is sold ahead into midsummer. The price has advanced from 6@8c. to 8@9c. per lb., while flake is firmer at 7½@8½c. per lb. *Solvent naphtha*, pure water white, jumped to 25@31c. from 27c. per gal. of last week. *H acid* is being sold by dealers at $1.75@$1.90 per lb., with very little material available at these prices. The demand on *cresol* has been steady during the week and the price held firm at 16@18c. per lb.

Waxes

There has been the usual amount of business in this market during the week. The only fact worthy of comment is continued shortage of the *paraffine* grades. Foreign buyers are still active inquirers on these items.

Naval Stores

There has been no activity in this market during the past week. Prices on *turpentine* have gone up, but there is no material available at any price. Current quotations range from $2.35@$2.40 per gal. with a steady increase looked for until relief can be received from Savannah.

Rosins are in the same condition, all prices being nominal. It is reported that there are several ships on the way from the South, but it may be impossible to unload them because of the longshoremen's strike.

Crude Rubber

This market during the past week has remained unchanged. The rate of exchange is the controlling factor at present. If the rate goes up sellers withdraw their low offerings; if the rate goes down buyers refuse to take any active part. Outside of the bare necessities, consumers are not in the market to any extent.

Oils

The increasing shortage of *linseed oil* has caused a strengthening in this market and no immediate relief is in sight from the Argentine crop, as it is the opinion of many that the new seed will not be able to meet the demand. Current quotations are: $1.84 raw car lots and $1.87 for boiled, tank cars. *Cottonseed* is firm at former prices, crude being quoted at 18@19c. per lb., while winter yellow is listed at 22@24½c. per lb.

Miscellaneous Materials

This branch of the market has held firm throughout during the past week, *barytes* being the most active item on the list. A rise in price is looked for shortly. Current quotations: Domestic white floated, $35@$40, and off color, $25@$30 per ton.

Chicago, March 24, 1920.

Comparatively quiet markets with prices unchanged and firm rule in all branches of the local chemical trade with the exception of alkalis, vegetable oils and naval stores. *Alkalis* continue under heavy demand from exporters and every day sees a slight boost in prices. The same is true of *naval stores*, but *vegetable oils* continue to be very weak. Business of the past two weeks has been marked by no spectacular feature.

Conditions brought about by the shortage in *turpentine* are forcing many industries which formerly used pure gum spirits to use wood turpentine. This product, although not equal in purity to the pure gum grade, is being substituted and can be produced in unlimited quantity and is quoted at a cheaper price. The principal disadvantage of this substitution is the offensive smell of wood turpentine. If present conditions remain unchanged, it is possible that the industrial arts will, in time, all come to the use of wood turpentine, leaving the gum spirits for use in paints.

Heavy Chemicals

As has been the case for several weeks, the demand for alkali products has greatly exceeded supply. Spot stocks are close to the vanishing point. On what is purely a sellers' market, *solid caustic* is now bringing $6.25 per cwt. f.o.b. works in cars, with a half cent higher on small spot transactions. The *granulated* commands 6c. at the works. *Soda ash*, in sympathy with the other items of this classification, is quoted at $3 per cwt., f.o.b. works. *Bleaching powder*, quoted two weeks ago at $3.50, now brings 4@5c. per lb., depending on how badly it is needed. *Sal soda*, in cars, is quoted at $1.50 per cwt., while jobbers are asking as high as $2.25 in small lots.

On the strength of anticipated receipts from abroad, recent panicky conditions in *sodium nitrite* have partially subsided. Current transactions are at 35c. per lb. While this seems high, it will take a considerable increase in supply over that now available to reduce it materially. Only nominal quotations are available on all grades of *alcohol*. A few small actual transactions have occurred in denatured, 180 proof, at $1 a gal. *Formaldehyde* continues to bring whatever the buyer can offerd, actual quotation being around $1 per lb. *Sodium bichromate* shows further reduction, now going for 35c. per lb., spot, in small quantity.

White sal ammoniac, the shortage of which is said to be due to transportation troubles, remains high, current price being 19@20c. per lb. for immediate delivery. Strong lead market has developed high prices in lead products, *acetate* being firm at 14½c. per lb. and *arsenate*, powdered, at 30@31½c. per lb.

The most important factor in connection with *acids* is the difficulty in securing containers, both drums and tanks, in which to make shipment. Firmness in price is noted, with *boric* at 16c. in cars and *oxalic* at 44@47c. in cars. Stocks of *hydrofluoric* seem to be seriously depleted, current quotation being 8@8½c. per lb.

Coal-Tar Products

Conditions are practically unchanged since last reported. The steady improvement in supply continues and a slight reaction in price has resulted. *Benzol* and *tuluol* are firm at 28c. in carloads. *Anilines* are some easier, the *oil* going at 32@35c. per lb. and the *salts* at 42@50c. per lb., with the latter figure prevailing in most cases. *Dimethylaniline* is being quoted at $1.60 per lb., but this quotation is purely nominal, no stocks being on hand. *Salicylic acid* is slightly under previous quotation. Present figures for technical grade, 47c.; for U. S. P., 57@58c. per lb. While no change has recently been noted in *naphthalene*, a decided firmness is noted due to dwindling stock. The ruling price for *flake* from stock is 8c. per lb., and 10c. for balls.

Vegetable Oils

This market continues weak. With buyers controlling the market, prices remain at a low level. *Cocoanut oil* in sellers' tanks, f.o.b. coast, is still quoted at 17c., and *soya bean oil* at 16@16½c. The *linseed oil* market remains very strong; transportation troubles, lack of imports of South American seed and uncertainty as to the extent of the new crop tend to a bull market. Present quotation in tank cars f.o.b. Chicago is $1.66@$1.71 per gal. In barrels, in quantity up to five, jobbers are getting $2.05.

Flotation Oils—Naval Stores

Turpentine continues to soar. Actual stocks on hand are known to aggregate only about 20 per cent of the normal for this time of year and the coming crop is an unknown factor. Those claiming to be in a position to know foretell a very scant crop, which means that present scarcity may even be made worse. Every few days sees a fresh advance and only a fraction of the demand is being supplied. Price in cars f.o.b. Chicago is $2.38@$2.40, and in barrels $2.52 per gal. No price change is noted on *pine oil*, but existing quotations of $1.60 for 0.933 pure steam distilled and $1.55 for destructively distilled are nominal, as demand so greatly exceeds supply. *Rosin* and *pine tar oil* show no material change in price, but demand is less.

Fertilizers

The expected slump has occurred. Stocks are now plentiful and calls from all sources are becoming few. Most seasonal demands are supplied and manufacturers are running to store stocks for future requirements. Ruling prices on *high-grade blood* are: For ground, $8.25@$8.40 per cwt.; on *tankage*, for high-grade ground, $7.65@$7.90 per cwt., and for low-grade ground, $7@$7.25 per cwt.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.		$0.60 – $0.65

Potassium chlorate, crystals	lb.	.25 – .28	.21 –
Potassium hydroxide (caustic potash)	† lb.		.30 – .35
Potassium iodide	lb.	.19 –	3.35 – 3.60
Potassium nitrate	lb.		.21 –
Potassium permanganate	lb.		$0.65 – $0.95

†(See New York market letter).

		Carlots	Less Carlots
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1.20
Potassium prussiate, yellow	lb.	.34 – .36	.40 – .70
Potassium iodide	ton	$225.00	
Rochelle salts (see potassium sodium tartrate)			
Salammoniac (see ammonium chloride)			
Saltpeter (see potassium nitrate)			
Salt cake (see sodium sulphate)			
Salt cake	ton	21.00 – 22.00	
Silver cyanide (fresh made)	oz.		1.25 –
Silver nitrate (fresh made)	oz.		.77 – .82½
Silver nitrate (recrystallized)	oz.		– 3.50
Soda ash, light	100 lb.	2.50 – 2.60	– 3.55
Soda ash, dense	100 lb.	2.70 – 2.75	
Sodium acetate	lb.	.06½ – .07	.07 – .08
Sodium arsenate	100 lb.	2.40 –	2.75 – 3.00
Sodium bicarbonate	lb.	.03 – .04	.05 – .06
Sodium bichromate	lb.	.13 – .14	.15 – .16
Sodium bisulphate (nitre cake)	ton	7.00 – 7.50	8.00 – 10.00
Sodium bisulphite Powered	lb.	.05½ – .06½	.07 – .07½
Sodium borate (borax)	lb.	.08½ – .08¾	.09 – .09½
Sodium carbonate (sal soda)	100 lb.	1.25 – 1.35	1.40 – 1.50
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	5.00 – 6.00	6.10 – 6.25
Sodium hyposulphite	lb.		.03 – .04
Sodium molybdate	lb.	2.50 –	3.25 –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	† lb.		.35 – .45
Sodium peroxide, powdered	lb.		.30 – .32
Sodium phosphate, dibasic	lb.	.03½ – .04½	.04½ – .05
Sodium potassium tartrate (Rochelle salts)	lb.	.40 – .42	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .29	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01½ – .02	.02 – .02½
Sodium silicate, solution (60 deg.)	lb.	.02½ – .03	.04 – .05
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.15 – 1.50	1.60 – 2.00
Sodium sulphide, crystal, 60–62 per cent conc.	lb.		.05 – .06
Sodium sulphide, fused, 60–62 per cent conc.	lb.	.03½ –	.04 – .06
Sodium sulphite, crystals	lb.	.25 –	.28 –
Strontium nitrate, crystals	lb.	.05½ –	.06 –
Sulphur chloride	ton	22.00 –	
Sulphur, crude	lb.	.09 –	.10 – .12
Sulphur dioxide, liquid, cylinders	100 lb.	3.35 –	3.40 – 3.65
Sulphur (sublimed), flour	100 lb.	3.20 –	3.30 – 3.40
Sulphur, roll (brimstone)	lb.	.42½ –	.46 – .50
Tin bichloride (stannous)	lb.	.50 – .60	.65 –
Tin oxide	lb.		.20 –
Zinc carbonate, precipitate	lb.	.13 –	.13½ – .15
Zinc chloride, gran.	lb.	.49 –	.50 – .60
Zinc cyanide	lb.	.11½ – .12½	.13 – .15
Zinc dust	lb.		.19 – .21
Zinc oxide, U. S. P.	lb.	.03½ – .03¾	.04 – .04½
Zinc sulphate			

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00	$1.10
Alpha naphthol, refined	lb.	1.40	1.60
Alpha naphthylamine	lb.	.40	.50
Aniline oil, drums extra	lb.	.34	.45
Aniline salts	lb.	.42	.48
Anthracene, 80% in drums (100 lb.)	lb.	.75	1.00
Benzaldehyde (f. f. c.)	lb.	2.00	2.10
Benzidine, base	lb.	1.25	1.35
Benzidine, sulphate	lb.	1.00	1.15
Benzoic acid, U.S.P.	lb.	.90	1.10
Benzoate of soda, U.S.P.	lb.	.80	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25	.31
Benzyl chloride, 95-97%, refined	lb.	.35	.40
Benzyl chloride, tech.	lb.	.25	.35
Beta naphthol benzoate	lb.	.50	.65
Beta naphthol, sublimed	lb.	.70	.90
Beta naphthol, tech	lb.	.45	.55
Beta naphthylamine, sublimed	lb.	2.25	2.35
Cresol, U. S. P., in drums (100 lb.)	† lb.	.16	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85	1.00
Cresylic acid, 50%, first quality, drums	gal.	.60	.70
Dichlorbenzol	lb.	.07	.10
Diethylaniline	lb.	1.40	1.50
Dimethylaniline (nominal)	lb.	.95	1.50
Dinitrobenzol	lb.	.26	.37
Dinitrochlorbenzol	lb.	.25	.30
Dinitronaphthaline	lb.	.45	.55
Dinitrophenol	lb.	.32	.36
Dinitrotoluol	lb.	.38	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38	.40
Diphenylamine (nominal)	lb.	.55	.65
H-acid (nominal)	† lb.	1.75	1.90
Metaphenylenediamine	lb.	1.15	1.80
Monochlorbenzol	lb.	.12	.15
Monoethylaniline	lb.	1.50	1.75
Naphthaline crushed, in bbls. (250 lb.)	† lb.	.08	.09
Naphthaline, flake	lb.	.07	.08
Naphthaline, balls	lb.	.08½	.10
Naphthionic acid, crude	lb.	.70	.85
Nitrobenzol	lb.	.14	.19
Nitro-naphthaline	lb.	.30	.35
Nitro-toluol	lb.	.20	.30
Ortho-amidophenol	lb.	3.75	4.25
Ortho-dichlorbenzol	lb.	.15	.20
Ortho-nitrophenol	lb.	.80	1.25
Ortho-nitro-toluol	lb.	.25	.40
Ortho-toluidine	lb.	.25	.45
Para-amidophenol, base	lb.	2.50	3.50
Para-amidophenol, HCl	lb.	2.50	3.25
Para-dichlorbenzol	lb.	.12	.18
Paranitraniline	lb.	1.00	1.35
Para-nitro-toluol	lb.	1.35	1.50
Paraphenylenediamine	lb.	2.15	3.00
Paratoluidine	lb.	1.75	2.50
Phthalic anhydride	lb.	.65	.75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12	.25
Pyridin	gal.	2.00	2.50
Resorcin, technical	lb.	4.25	4.50
Resorcin, pure	lb.	6.25	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.45	.50
Salicylic acid, U. S. P.	lb.	.55	.60
Salol	lb.	.90	1.00

Solvent naphtha, water-white, in drums, 100 gal. †	gal.	$0.25 —	$0.31
Solvent naphtha, crude, heavy, in drums, 100 gal. †	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark †	lb.	$0.38 —	$0.40
Beeswax, refined, light †	lb.	.40 —	.41
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	.80 —	.88
Carnauba, No. 2, regular (nominal)	lb.	.60 —	.70
Carnauba, No. 3, North Country (nominal) †	lb.	.43 —	.45
Japan	lb.	.17 —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	..... —	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.08
Paraffine waxes, refined, 128-130 m.p.	lb.	.11 —	.11¼
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.14
Stearic acid, single pressed	lb.	.26 —	.27
Stearic acid, double pressed	lb.	.32 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist.	gal.	.....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.47
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	†280 lb.	$17.95 —	$18.25
Rosin E-I	280 lb.	18.75 —	19.00
Rosin K-N	280 lb.	19.45 —	21.00
Rosin W. G.-W. W.	280 lb.	22.00 —	22.50
Wood rosin, bbl.	280 lb.	15.50 —	17.50
Spirits of turpentine	gal.	..... —	2.35
Wood turpentine, steam dist.	gal.	..... —	2.25
Wood turpentine, dest. dist.	gal.	..... —	2.10
Pine tar pitch, bbl.	200 lb.	8.40 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	15.00
Retort tar, bbl.	500 lb.	15.00 —	15.50
Rosin oil, first run	gal.	.92 —	.95
Rosin oil, second run	gal.	.94 —	.97
Rosin oil, third run	gal.	1.10 —	1.15
Rosin oil, fourth run	gal.	1.17 —	1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.40½ —	$0.42
Upriver coarse	lb.	.30½ —	.32
Upriver caucho ball	lb.	.32½ —	.33
Plantation—First latex crepe	lb.	.47½ —	.50
Ribbed smoked sheets	lb.	.47½ —	.48¾
Brown crepe, thin, clean	lb.	.45 —	....
Amber crepe No. 1	lb.	.46 —	.47

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19 —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.23
China wood oil, in bbls.	lb.	.24½ —	.25½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18 —	.19½
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½ —	.23
Corn oil, crude, in bbls.	lb.	.18 —	.19
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½ —	.18
Cottonseed oil, summer yellow	lb.	.19½ —	.20½
Cottonseed oil, winter yellow	lb.	.22 —	.24½
Linseed oil, raw, car lots	gal.	1.84 —	.....
Linseed oil, raw, tank cars	gal.	1.77 —	.....
Linseed oil, boiled, car lots	gal	1.87 —	.....
Olive oil, commercial	gal.	2.50 —	3.00
Palm, Lagos	lb.	.16 —	.16½
Palm, bright red	lb.	.15¾ —	.17¾
Palm, Niger	lb.	.15 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.20½ —	.22
Peanut oil, refined, in bbls.	lb.	.27 —	.28
Rapeseed oil, refined in bbls	gal.	1.70 —	1.78
Rapeseed oil, blown, in bbls.	gal.	1.80 —	1.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.18½ —	.23
Soya bean oil, tank cars, f.o.b. Pacific coast	lb.	.15¾ —	.20

FISH

Winter pressed Menhaden	gal.	$1.17 —	$1.18
Yellow bleached Menhaden	gal.	1.20 —	1.22
White bleached Menhaden	gal.	1.23 —	1.24
Blown Menhaden	gal.	1.30 —	1.35

† (See New York market letter)

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.04½ —	.05½
Blanc fixe, pulp	ton	30.00 —	50.00

Talc, domestic	ton	20.00 —	60.00
Talc, imported	ton	60.00 —	70.00

*Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick net ton	75-80 at Chester, Penn.
Chrome cement net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay 1,000	38-45 at Clearfield, Penn.
Clay brick, 2nd quality 1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in. net ton	80-85 at Chester, Penn.
Silica brick 1,000	45-50 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.22
Ferro-manganese, 70-80% Mn	gross ton	180.00 —	225.00
Spiegeleisen, 16-20% Mn	gross ton	50.00 —	70.00
Ferro-molybdenum, per lb. of Mo	lb.	2.25 —	2.75
Ferro-silicon, 50%	gross ton	80.00 —	90.00
Ferro-silicon, 75%	gross ton	150.00 —	200.00
Ferro-silicon, 10-15%	gross ton	60.00 —	70.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90 —	1.10
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50 —	7.50

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	.....
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	.....
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	14.00
Fluor spar, gravel, f.o.b. mines	net ton	..... —	25.00
Manganese ore, 45% Mn and over	unit	.75 —	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00 —	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00 —	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.25 —	6.75
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

*Government prices.

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

PASADENA — Samuel Storrow has awarded the contract for the construction of a 2-story, 85x140-ft. factory for the manufacture of bricks, on Raymond Ave., near Dayton St., to L. P. Pomeroy, 751 North Catalina St., at $38,615.

Connecticut

MERIDEN—The International Silver Co., 48 State St., has awarded the contract for the construction of two 1-story additions to present manufacturing plant on George St., to the Immick Co., State St. Estimated cost, $40,000.

Illinois

CHICAGO—The Advance Spring & Wire Co., 1749 Carroll Ave., plans to construct a 2-story annex to the present plant on the southwest corner of Carroll Ave. and North Wood St. Estimated cost, $125,000.

CHICAGO—The American Glue Co., 123 West Kinzie St., plans to construct a factory at 3640 Iron St. Estimated cost, $160,000. S. Scott Joy, archt.

CHICAGO—The Boyle Ice Co., 136 West Lake St., is building an artificial ice plant on Larrabee St. near Chicago Ave. Estimated cost, $200,000.

CHICAGO—The Troco Nut Butter Co., 30 North Michigan St., is constructing a building for the manufacture of food products, on the southwest corner of 37th and Iron Sts. Caleb E. Johnson, pres.

CHICAGO—The Western Campbell Ice Machine Co. plans to build a plant for the manufacture of ice machinery on Cornelia St. near the Chicago, Milwaukee & St. Paul Ry. Estimated cost, $150,000.

Iowa

DEXTER—The city has awarded the contract for the construction of a sewage disposal plant, to F. H. Christenson, Guthrie Center, at $12,465. Noted Feb. 18.

STANTON—The city has awarded the contract for the construction of a sewage disposal plant, to Harness Bros., Ottumwa, at $12,600. Noted Feb. 25.

TABOR—The city has awarded the contract for the construction of a sewage disposal plant to Ward & Weighton, Davidson Bldg., Sioux City, at $17,560.

Maryland

BALTIMORE—The Autogenous Welding & Machine Co., 1213-1223 Maryland Ave., has awarded the contract for the construction of a 1-story, 25x150-ft. addition to welding plant at 1223 Maryland Ave., to F. A. Condon, 1520 West Baltimore St. Estimated cost, $12,000.

BALTIMORE—The Emery Steel Castings Co., 210 Garrison Lane, has purchased the Pabst Brewery property on South Charles St. at the intersection of Hanover St. and the Baltimore & Ohio R.R. and plans to move its plant and equipment there. Alterations are being made to turn brewery buildings into a modern steel foundry. An electrical steel furnace will be installed in same.

ELKTON—The Bd. of Comrs. is having plans prepared for the construction of a filtration plant, etc. Estimated cost, $40,000. W. H. Mackall, pres. L. J. Houston, Fredericksburg, engr.

Massachusetts

NATICK—The New England Pressed Steel Co. plans to construct a 1-story, 55x85-ft. manufacturing plant addition. Estimated cost, $25,000.

Minnesota

MINNEAPOLIS—The Henepin Atomixed Fuel Co., 520 Security Bldg., is having plans prepared for the construction of a 1- and 2-story, 100x150-ft. fuel-crushing plant on B'way and Johnson St., N. E. Estimated cost, $150,000.

MINNEAPOLIS—W. T. Rawleigh Co., Freeport, Ill., has awarded the contract for the construction of a 2-story, 50x160-ft medicine factory on 10th Ave. N., and 3rd St., to the C. W. Lundquist Co., 1621 East Hennepin Ave. Estimated cost, $60,000.

Missouri

ST. JOSEPH—The St. Joseph Oil Co., southwest corner 4th and Duncan Sts., is having plans prepared for the construction of a 2-story fuel oil plant. Estimated cost, $200,000.

New Jersey

TRENTON—The Lenox Inc., Mead St., has awarded the contract for the construction of a 1-story, 100x394-ft., 2-story, 20x400-ft., and 3-story, 41x75-ft. buildings for the manufacture of ceramic ware, to Karno-Smith Co., Broad St. Bank Bldg., Estimated cost, $200,000.

TRENTON—The Pocono Rubber Cloth Co., East State St., plans to construct a 1-story factory. Estimated cost, $50,000. Karno-Smith Co., Broad St. Bank Bldg., engrs.

New York

BUFFALO—The Stron Steel Fdry. Co., Norris St., plans to build two 1-story additions to present factory at 33 Norris St. Estimated cost, $20,000.

ITHACA—The Cornell University Bldg. Committee had plans prepared for the construction of a 5-story chemical laboratory on the site of the home of President Jacob Gould Schurman on East Ave. Chemical equipment will be installed in same. Estimated cost, $1,500,000. Gibb & Waltz, Trust Co. Bldg., archts.

Ohio

CLEVELAND—Allen Osborn Co., archt. and engr., Rose Bldg., will soon award the contract for the construction of a 1-story, 100x200-ft. foundry on Dunham Rd., for the Minerva Engine Co., East 66th St. and Euclid Ave. Estimated cost, $60,000. C. S. Goby, pres. and treas.

ASHLAND—The city received bids for furnishing and installing filter equipment from the Amer. Water Softener Co., 1011 Chestnut St., Philadelphia, Pa., $34,000. Noted March 10.

CLEVELAND—The Collinwood Fdry. Co., 17004 Waterloo Rd., has awarded the contract for rebuilding the 1-story, 60x200-ft. foundry which was recently destroyed by fire, to A. A. Lane Constr. Co., Union Bldg. Estimated cost, $50,000.

Oklahoma

PAWHUSKA—The city had plans prepared for the construction of a filtration plant near the present water plant. The plant will have a capacity of 2,000,000 gal. per day. Estimated cost, $65,000. State Water Engr., Oklahoma City, engr.

Oregon

BEND—The Bend Water, Light & Power Co. plans to install an auxiliary pumping and sterilization plant including one 1,500-gal. per minute pump and construct a 30,000-gal. reservoir. Estimated cost, $12,000.

Pennsylvania

PHILADELPHIA—The Brown Instrument Co., Wayne and Windrim Sts., is constructing two buildings, one for the manufacture of recording thermometers and the other for a research department. Estimated cost, $100,000. R. P. Brown, pres.

PHILADELPHIA—The Dept. of Pub. Wks., City Hall, will soon award the contract for the construction of an intake house and for furnishing, delivering and installing various safety devices, including screens, etc., for the Bureau of Water Supply, 788 City Hall, at the Queens Lane Filters and at six other pumping stations.

Tennessee

MEMPHIS—The Fischer Lime & Cement Co., 269 Walnut St., is building a 2-story, 84x300-ft. warehouse on Walnut St. and Linden Ave. W. W. Fischer, pres.

MEMPHIS—The Southern Art Corp. has purchased a 6-acre site at the corner of Nelson St. and East Parkway and plans to construct a plant for the manufacture of art novelties on same. Estimated cost, $220,000. A. C. Jahl, vice-pres.

MEMPHIS—Swift & Co., 35 Union Ave., plans to construct an oil refinery and lard compound plant to have a capacity of 1,000,000 lb. per week. S. L. Kopald, mgr.

Texas

RANGER—The Thurber Earthen Products Co. is building a large rock crushing plant just east of here on the Hagerman land along the Texas & Pacific R.R.

DALLAS—The Fleischman Co., manufacturer of yeast, 711-13 North Ervay St., has purchased a site here and is having plans prepared for the construction of the first unit of a factory on same. Estimated cost, $1,000,000, ultimate cost, $1,500,000. Address G. W. Neary, 4630 Munger Ave.

Washington

SPOKANE—John G. F. Hieber, 2011 1st Ave., is having plans prepared for the construction of a 3-story, 73x160-ft. fruit juice plant. Sterilization coils, cooling coils, etc., will be installed in same. Estimated cost, $100,000. H. E. Smith, 1211 Old Natl. Bank Bldg., engr.

Wisconsin

CUDAHY—The Federal Rubber Co. will build a 6-story, 160x220-ft. factory on Packard Ave. Work will be done by day labor.

MARKESAN—E. W. Laper, village clk., will soon award the contract for the construction of sewage disposal plants, etc. Address G. C. Hank, 465 Sidney St., Madison.

British Columbia

NEW WESTMINISTER—The Imperial Oil Co., Cambie and Smith Sts., Vancouver, has awarded the contract for the construction of a distributing plant, etc., to the Dominion Constr. Co., 509 Richards St., Vancouver, at $24,500.

Ontario

DES QUINZE—M. J. O'Brien, Renfrew, plans to construct a pulp and paper plant, etc., here. Estimated cost, $4,000,000.

LONDON—The Bd. Educ., City Hall, is having plans prepared for the construction of a collegiate building on Ridout St. Chemical and physical laboratory equipment will be installed in same. Estimated cost, $215,000. L. V. Carrothers, Hydro Offices, archt.

TULBURY—The Tullsary Brick & Tile Co., Ltd., manufacturer of all sizes of drain tile and red wire cut face brick, is in the market for Bensing automatic brick cutters, 9-in. capacity and drain tile cutters, 13½-in. capacity, etc.,

Quebec

IBERVILLE — The town has been ordered by the Provincial Bd. of Health to construct a filtration plant and improve waterworks system. Estimated cost, $25,000.

LEVIS—The town has been ordered by the Provincial Bd. of Health to construct a filtration plant and improve waterworks system. Estimated cost, $25,000.

SOREL—The town has been ordered by the Provincial Bd. of Health to construct a filtration plant and improve waterworks system. Estimated cost, $25,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive at St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 2. Headquarters will be at the Seneca Hotel.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meet-

ing in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHAMBER OF COMMERCE OF THE U. S. announces that its eighth annual meeting will be held at Atlantic City, April 27 to 29, the subject of which will be "Increased Production."

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theater: "Romance of Leather Making," Tuesday, April 13, at 4 P.M., E. A. Brand (*Lantern*); "Water Supply and Drainage in War Cantonments," Wednesday, April 21, at 4 P.M., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 P.M., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 P.M., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 P.M., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE ELECTRIC FURNACE ASSOCIATION will hold a meeting in Boston, April 8 to 10, together with the American Institute of Electrical Engineers and the American Electrochemical Society. The subject is "Electrically Produced Alloys and Power for Electrochemical Purposes." Headquarters will be at the Copley-Plaza Hotel.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INTERNATIONAL MINING CONVENTION will be held in Seattle April 7 to 10.

THE [illegible] STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MINE INSPECTORS' INSTITUTE OF AMERICA will hold a meeting at Cleveland, Ohio, July 13.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5 which will be held in Glace Bay.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Industrial Notes

THE EAGLE-PICHER LEAD CO., Chicago, Ill., at the annual meeting held in Cincinnati on Feb. 17, elected Dr. John A. Schaeffer vice-president of the company in conjunction with his former position as chief chemist and chief metallurgist. His headquarters will be in the Railway Exchange Bldg., St. Louis. R. E. McCormack, formerly of Joplin, Mo., will be his assistant.

TECHNICAL ADVERTISING SERVICE, INC., 1132 Broadway, New York City, has recently enlarged its technical staff and opened an export service division under the management of J. S. Beckett, a chemical engineer of wide experience in laboratory, plant and construction work. This service offers to exporters answers to such inquiries as "Please send me a complete equipment for a metallurgical laboratory 12 x 17 ft. sq." or "a plant to make rubber heels," and is equipped to take care of any inquiry in the technical field, covering mechanical, chemical, civil, mining and metallurgical engineering. This department draws up complete and detailed specifications for all equipment covered by the inquiry, obtains quotations from the manufacturers, places the order and follows it through until the material is delivered as specified and on time at the dock or alongside the steamer.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa., announces the appointment of Arthur Elliott Allen as district manager at New York, to succeed Edward D. Kilburn, who has been elected vice-president and general manager of the Westinghouse Electric International Co.

H. DEVERELL announces that he has sold his interest in and severed his connection with Deverell, Spencer & Co. He will be engaged hereafter in the elevating, conveying and transmission machinery business, with offices at 1401 Lexington Bldg., Baltimore, Md.

THE CHEMICAL EQUIPMENT CO., Chicago, is moving to a new and larger plant at 2457-59 South Western Ave. The general officers will remain at 910 Monadnock Bldg.

THE BUFFALO FORGE CO., Buffalo, N. Y., at a recent meeting elected the following new officers: Henry W. Wendt, president; Edgar F. Wendt, vice-president and treasurer; Henry W. Wendt, Jr., vice-president and secretary; C. A. Booth, vice-president and sales manager. The new directors include the above-named officers, and in addition H. W. Whiting.

GLANDER & CO., formerly at 115 Broadway, New York City, are now located at 568 Broad St., Newark, N. J.

DEVERELL, SPENCER & CO., Baltimore, Md., announce that John C. Carter has purchased H. Deverell's interest in the company, and will be actively associated with J. H. Spencer. The name of the company will shortly be changed to the Spencer Construction Co.

THE GENERAL NAVAL STORES CO., with general offices at 90 West St., New York, has recently made a material expansion of the facilities in Chicago, to handle the pressure of business at that point. Enlargements trebling the office space in the McCormick Bldg. and increasing the warehouse and yardage space at 37th Street and Normal Ave. from 10,000 to 25,000 sq.ft. and installing storage tanks are now in process. Yardage expansion will give railroad trackage, which the company has not previously enjoyed. This company is the exclusive agent for the output of the Newport Co., a large producer of pine tar products, with works at Bay Minette, Ala., and Pensacola, Fla. It also has an office in St. Louis, Mo., and maintains stocks in Cincinnati, Detroit, Philadelphia, Norfolk and Denver.

THE ELECTRIC FURNACE CO., Alliance, Ohio, has opened a Middle Western office at 301 Frisco Bldg., St. Louis, Mo., in charge of W. E. Prosser.

THE TULSA LABORATORIES, formerly owned by James H. Holden, have been taken over by H. R. Rowe, W. A. Goldstrap and Roy L. Ginter. The new owners are putting in new supplies and equipment and are prepared to make oil field tests on casinghead and natural gas, also efficiency tests on gasoline plants where boiler trouble is experienced. In the laboratory they will handle oil and general analytical work, including complete gas analysis and drug assays.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, announces that arrangements have been made with the Wellman Bibby Co., Ltd., 38 Kingsway, London, W. C., 2, England, to act as its representative in Great Britain and Ireland for the sale of the American steam ash conveyor. It is the intention of the Wellman Bibby Co. to manufacture the American steam ash conveyor in England.

THE JEFFREY MFG. CO., Columbus, Ohio, has opened a new branch office in Los Angeles, Cal., in charge of F. R. Field, formerly manager of the Denver office. This addition to branch offices has been made necessary to give adequate service to clients in California, Arizona, Nevada and the State of Sonora, Mexico.

THE ROME WIRE CO., Rome, N. Y., has recently authorized an increase in the capital stock to $4,000,000 of 7 per cent first preferred and $5,650,000 common. The shares in each issue are $100 par value. The company's main plant is located at Rome, N. Y., on the New York Central R.R., and on the New York State Barge Canal. The land comprises twenty-two acres with 348,000 sq.ft. of modern factory buildings, fully protected by sprinkler equipment. All of the buildings have been constructed since 1905 and the larger part of them since 1914. The equipment is all modern and first class in every particular. The Buffalo plant consists of eleven acres of land in the northeastern part of the city, on the D., L. & W. R.R., with excellent trackage facilities and well-constructed buildings adapted to the manufacture of electrical wires and cables. A large addition is under construction at this branch.

THE AMERICAN ASSOCIATION OF COMMERCE AND TRADE IN BERLIN (American Chamber of Commerce) has just begun the monthly publication of the *Transatlantic Trade* in the interests of the American manufacturer, exporter and importer. The first issue is a 32-page magazine containing reports of commercial and industrial conditions in Germany, and opportunities for American goods in that country. Names of firms open for commercial connection with American manufacturers and other items of commercial interest are given. The subscription price in the United States is $2 per year.

THE WESTINGHOUSE ELECTRIC & MFG. CO., Pittsburgh, Pa., has given an insurance policy for $500 without cost to each employee who has been in the company service for six months or more. After April 1 employees may increase the value of their policies to amounts varying from $1,000 to $2,000 depending upon their length of service and continuity of saving. All employees who have been in the company's service for six months or longer and who deposit a sum each payday in the employees' savings fund equal to 2 per cent or more of their earnings will not only receive 4½ per cent interest compounded semi-annually on such deposits but in addition will automatically have their insurance increased to amounts up to $2,000, depending on the length of time they have been with the company. This insurance is to be made effective at all of the various offices and plants of the Westinghouse Electric Co. and will affect approximately 50,000 persons.

THE MOTOR TRUCK OWNERS OF NORTH AMERICA is a new organization of motor truck users and operators formed at the recent automobile shows in New York, Chicago and other cities. It is an outgrowth of the tri-state association which included Indiana, Ohio and Pennsylvania. Indianapolis, Ind., is the new headquarters.

THE GLIDDEN STORES of Cleveland, Ohio, will open a branch at 157 Madison Ave., Memphis, Tenn., for the sale of varnishes, insecticides and sundry products. B. F. Hammond has been appointed district manager.

THE TOLEDO SCALE CO. has established a branch sales office at 11 South Third St., Memphis, Tenn., under the direction of W. D. Weidlein.

Manufacturers' Catalogs

THE QUIGLEY FURNACE SPECIALTIES CO., New York, has issued a folder on low-cost per heat-hour of pots (cyanide chloride, lead) and boxes (carbonizing annealing).

THE JOSEPH DIXON CRUCIBLE CO., Jersey City, is distributing, to any foundryman requesting it, a copy of booklet No. 190-A, entitled "Crucibles—Their Care and Use." This company has found that many foundrymen do not fully appreciate the importance of keeping and handling their crucibles in a manner which will insure the greatest number of heats with the least danger of accidents, and this booklet is being distributed to emphasize this point.

THE DENVER FIRE CLAY CO., Denver, Col., announces a new catalog on D.F.C. Clay Products. This attractive booklet gives in 20 pages descriptions and illustrations of such products as annealing cups, assay crucibles, annealing cup trays, tall form crucibles, crucible covers, melting crucibles, special crucibles, crucibles for melting platinum, etc., together with prices.

THE HIRES TURNER GLASS CO., Philadelphia, Pa.: Bulletin No. 11-A, entitled "Corrugated Wire Glass for Industrial Buildings," illustrates and describes the different types of corrugated wire glass and the purposes to which they can be put. Photographs of actual installations are shown.

THE GRISCOM-RUSSELL CO., New York City, is issuing Bull. 311, on the Reilly Evaporator, submerged type. Illustrations are given of the evaporator closed and open, with a steel shell, single manifold, and also with a cast-iron shell, double manifold, together with a description; together with instructions for marine installation of a multicoil evaporator and distiller plant.

THE VINELAND SCIENTIFIC GLASS CO., Vineland, N. J., is issuing a "loose-leaf" compilation of illustrated price lists of items of chemical, medical, pharmaceutical, and surgical glassware.

Spring Conventions Of Chemical Societies

THE month of April brings the customary spring meetings of the American Electrochemical Society and the American Chemical Society—two of the principal events of the year in chemical circles. The electrochemists, who meet at Boston this week, are provided with an unusually good program, with three symposia —on colloid chemistry, electrically-produced alloys and power for electrochemical purposes. The first of these will be led by the Society's president, W. D. BANCROFT, himself a leading authority on the subject. The second has been contributed by a large number of manufacturers. The third, being the joint product of the Society and the American Institute of Electrical Engineers, will serve an excellent purpose in bringing together the producer and consumer of electric power. It is seldom that the programs of the American Electrochemical Society have excelled that of the Boston meeting.

Less is known at this writing about the general plan or the details of the meeting of the American Chemical Society in St. Louis next week, although we may assume from past experience that it will prove to be a successful meeting. We believe it is unfortunate that the American Chemical Society has never seen fit to follow the customary practice of the electrochemists, mining engineers, and other associations of technical men in publishing papers in advance of the meeting so that those who attend may know what to expect and be prepared with discussion on subjects with which they are familiar. In our judgment the meetings of the American Chemical Society will never hold for its members the attraction and interest which other professional societies secure until there is a change in policy in this respect. Some difficulty may be encountered in adopting this plan, because the inertia of authors must be overcome; but the principal requisite is decision upon the part of the Society's officers. Once this is reached, authors will realize they must conform thereto if they are to find a place on the program. If the change is too drastic to be applied throughout, a beginning could be made by applying it to the larger and better established sections and divisions. It is largely a question of official attitude.

Chemistry and the Interstate Commerce Commission

IN HANDING down a recent decision on the transportation of sodium nitrate the Interstate Commerce Commission made some startling observations on the properties of that well-known substance. After announcing the rates from the seaboard to inland points, the Commission proceeded to dilate upon the chemistry of sodium nitrate and stated that it oxidizes rapidly when exposed to the atmosphere and reacts violently in combination with water. These are indeed shocking details to reveal to chemists who thought they were quite familiar with the characteristics of sodium nitrate.

It may be that this salt is particularly unfortunate in regard to its reputation, for an honorable Senator recently insisted at a committee hearing that Chilean saltpeter is highly explosive and can be ignited by a match.

The facts would not be worth recording merely for the purpose of provoking a smile, but they are significant of the increasing complexity of our daily business life and the necessity for technical knowledge in the transaction of the Government's business. The Interstate Commerce Commission undoubtedly knows much about railroad rates, but is badly in need of a technical adviser when it comes to chemistry.

In Support of the Chemical Warfare Service

WHEN the House of Representatives passed its Army reorganization bill and made the Chemical Warfare Service a separate organization, the outlook for that branch of the service was distinctly improved. It now remains for the Senate to display equally good judgment and assure the country of an Army unit skilled in the means of offensive and defensive gas warfare and able to train the remainder of the troops.

If the Chemical Warfare Service finally becomes established as a separate branch of the Army, it will not be due to the efforts of the Secretary of War or the Chief of Staff, but rather in spite of their opposition. To no one more than to Colonel A. A. FRIES will the retention of the Service be due, if the Senate follows the example of the House. He it was who had charge of chemical warfare on the other side and observed its effects and value. Returning to this country, he first preached the doctrine of the humanity of gas warfare and showed by actual figures the low percentage of death among gas casualties as compared with the results of artillery and infantry fire. His convictions led him to work for the retention of the Service even when its demobilization had been ordered, and his zeal and enthusiasm converted others to his viewpoint. In fact, the revulsion of feeling against gas warfare gradually dissipated to such an extent that no Congressman raised his voice against it when the House bill was passed.

It required no gift of prophecy to foresee the immediate and insistent demand that will arise for chemical warfare if this country again becomes involved in war. That and the air service will be the two new means of offense and defense that will be most urgently needed. Civilian chemists will again be called to the

colors in their professional capacity. In the meantime the least that the Army can do is to retain the skeleton of an organization for the prosecution of research and the training of troops. The latter is in itself a huge problem when it is considered that the National Guard as well as the Regular Army must be trained. Add to this the responsibility of the Chemical Warfare Service for the production of chemical supplies for the entire Army, and we have a task requiring a larger organization than the minimum which has been suggested. The Senate has here an opportunity to urge an increase in the peace-time minimum so that the duties can be performed by Chemical Warfare officers and men, without resorting to special details from other branches of the service which probably would be returned to their original branches in case of hostilities, thus crippling the Chemical Warfare Service when most urgently needed.

An official estimate of the minimum peace-time strength of the Chemical Warfare Service is 171 officers and 2,057 enlisted men, and the Senate will do well to accept the suggestion. It should also see that a clause is introduced defining the duties of the Service, as otherwise a loophole will be left through which opponents of the Service may undermine its independent status and even dismember it on the score that it has no excuse for existence. The duties can well be defined to include the production of gases and smokes for offense, appliances for gas defense, research and investigation in chemical warfare, and the training of the Army in offensive and defensive methods of gas warfare. Until this is done, and the Chemical Warfare Service is firmly established in the Army, the country cannot feel that Army reorganization has been accomplished in the most intelligent and effective manner.

A Balance Nicely Struck

WE ALWAYS object to the charge, sometimes made by narrow-minded scientists, that the engineer is only a craftsman who commercializes science and who sees in a truth only the prospect of monetary gain. On the other hand, we equally regret to hear the "practical" man give vent to unsympathetic criticism of the scientific investigator.

In his address before the American Association of Petroleum Geologists on March 18, GEORGE OTIS SMITH, director of the United States Geological Survey, has struck a splendid balance between the call of pure scientific research and the problems of industry and the arts. He refers to applying the known truths of science for human benefit as "the hallmark of true value"; but he hastens to add the comment: "In a way I suppose we may regard science as an expendible resource; those who apply science to the needs of man seem to require fresh supplies from which to draw for their use. At least it is true that each new advance in the engineering arts calls for a corresponding reinforcement by scientific truth."

It is always a difficult matter to tell when the results of technical investigation will be of value in their application. It is a long step from the test-tube to a satisfactory balance-sheet on a year's plant operations. But the test-tube stage is important, none the less. The executive who plans for an extensive chemical industry (and which of our industries is not in some measure chemical?) without including in his calculations an appropriate allowance for research is likely to find himself left far behind in the industrial race. It is proper that the executive expect this research department to show convincingly that it pays good dividends; but in this department there will always be some problems under study that "we know will never pay," as one director of research put it.

It is fortunate that we have those who love the labors of pure research and who stick to their work despite the charge that they are "impractical acedemic theorists." By their explorations they constantly push back the boundaries of technical ignorance and thus leave more territory for settlement and cultivation by those who follow. Such pioneers perhaps never grow rich; but what pioneer ever does? However, they derive a wonderful store of new experiences which in themselves are a real reward; and they also deserve our cordial support and respect.

There is no ground for contest between the investigator and the one who will apply his discoveries in the useful arts. There is room and need for both. And above all there is need for mutual respect and co-operation.

Conserving Radium As a National Asset

WHEN the Bureau of Mines investigated the radium-bearing ores of Colorado and Utah in 1912 it disclosed a national asset unknown prior to that time, and one that has not been fully appreciated since then. Prior to 1913 the world's production of radium came from Austria, but since then the United States has produced and is producing more of it than all other countries combined. Of the known total world's production of from 100 to 110 grams of radium element it seems likely that domestic ores have yielded 75 to 80 grams, of which say 70 grams has been extracted in this country and the balance abroad.

Early in the development of the radium industry in the West, officials of the Bureau of Mines sounded a warning against the dissipation of our supply of radium, either through non-essential uses in the arts or by unrestricted export to foreign countries. The supply of ore was even then known to be limited, and the life of the mines could be predicted with sufficient accuracy to foresee their exhaustion in a few years. Today the supply of ore seems sufficient to last not more than ten years if the present rate of production and price of radium are maintained.

It seems evident, therefore, that if a conservative note of warning was warranted eight years ago it should now be amplified into a blast of trumpets. Not all of the radium hitherto produced, say 100 grams, is today available for its principal use, viz., the treatment of cancer. Some of it has gone into the production of luminous paint and more of it was consumed during the war in making luminous dials on airplanes, luminous gunsights, etc. All of this is lost to science and medicine. Nor have we in this country in medical use today much more than 20 to 25 grams out of the 70 that our own ores are known to have produced.

If the United States is to accumulate any considerable supply of radium, it would seem high time to make a beginning. Through inquiry we learn that the treatment of cancer with radium is proving more and more successful every day, and that it is practically the only method of treatment in vogue in certain hospitals. But

even here there is danger of scattering the supply too widely, so that sufficient quantities are not available in one place to accomplish the best results. The crux of the matter seems to be that radium is so expensive that private interests cannot afford to purchase it in sufficiently large quantities for its most effective use. The solution of the problem would seem to lie in the private endowment of hospital funds for the purchase of radium or an appropriation by the Government for the same purpose. If the public interest is to be served we must depend on private philanthropy or Government support.

Railroad Efficiency And Steel Requirements

IT IS quite certain that two or three months ago a great many buyers of steel products were misjudging the volume of railroad demand for steel during the remainder of the year. Buyers were highly excited, estimating steel-producing prospects by the light production of the closing months of 1919, and fearing that railroad buying would cut off even a portion of the supplies they had been receiving. The buyers made the steel market, bidding higher and higher prices for steel, and there were evidences of a runaway market. Indeed, a runaway actually began, but it did not continue, rather merging into a condition in which fancy prices obtained for early deliveries, against relatively moderate prices for later deliveries. The result was a high premium market rather than a general runaway.

A clearer perception of the condition and prospects is now being reached, with the result that a more safe and sane market for steel is to be expected. The steel industry is beginning to function well again, the American Iron and Steel Institute's report indicating that steel ingots were produced during February at the rate of 44,200,000 gross tons a year, or 46 per cent better than the average rate during 1912 and 1913, by far the two best tonnage years before the war, and years of approximately equal tonnage. The increase in the rate from January to February was between 8 and 9 per cent, prospects being that March will show a further decided improvement, whereby the quarter's production will represent about 90 per cent of capacity, instead of the 75 per cent mentioned in some of the gloomy forebodings.

Reverting to the fears that the railroads would corral the steel market as soon as the lines were returned to their owners, it is high time that the public, not merely the general run of steel consumers, take a more rational and intelligent view of the work that lies before the railroads. It may be thought natural that when a shipper does not receive enough cars for loading from the railroad, or does not receive raw material because those from whom he buys do not get cars, the shipper should jump to the conclusion that the railroads should buy more cars, and keep on buying until they have enough. But if the shipper has two office boys and both are habitually very late to work he is hardly likely to solve the "problem" by continuing to put additional office boys on his payroll until he finds a good supply every morning at 9 o'clock or whatever his hour may be. He is more likely to look into the habits of the boys he is already paying.

Roughly speaking, there are about 2,500,000 freight cars in the country, a few less than that owned by the railroads, and a few more counting the private cars. The report for last December, by the way, showed 6.2 per cent of the cars "unserviceable," against 5.8 per cent the previous December, just after the Armistice. To add 10 per cent to the number would mean 250,000 cars, costing the better part of a billion dollars. When the roads have functioned well cars have moved, loaded, an average of nineteen miles a day, while when there is "car shortage" the movement is slower. Which would you rather do, spend the major part of a billion dollars or move cars 1.9 miles more per day? A fact that seems pertinent is that there are about 500 freight cars per freight locomotive. This looks hard for the locomotive but seems to give the freight car an easy time. Another noticeable fact is that when there are serious car shortages some of the yards and terminals are badly congested.

Undoubtedly the railroads need more cars, and they are buying some of those additional cars now. They need also to replace old cars, so productive of wrecks, by new cars. Beyond this they need much more motive power, much improvement of terminals and yards, and a great deal of block signaling of track that does not now render the service required of it. Simply to clutter up tracks with more cars will not make the railroads fully serviceable.

The railroad managers are, as a matter of fact, confronted with a very big problem, to put the lines in condition to render much more service and much steadier service. The problem is big financially and big from the engineering side. It is not one that can be solved by instructing the purchasing agent to rush into the market and buy everything at once that is to be had. During the remainder of this year the railroads will make only a beginning. Much more actual work will be done in 1921, and if things go right still more will be done in 1922. Railroad demand will engage relatively little of the steel-making capacity this year, but a great deal more in succeeding years if the railroad companies are able and willing to do their duty to the public.

Artistic Imagination For Engineering Workers

Art is always and everywhere the best way of doing a thing.

THIS definition by one of the *literati* is relevant to the engineering business in that it involves action. Art is concerned not only with museums of junk, philharmonic gatherings or brochures of purple paragraphs, as we are wont to connect it through long association, but applies to the creation or production of anything that is beautiful in its service to the industries and mankind.

An artistic conception of the vocation is essential to the engineer, for, genius or otherwise, he is a worker; and to work successfully he must be led by inspiration, not driven by necessity.

Burning Clay In Sanskrit

WITH the aid of skilled etymologists a committee of the American Ceramic Society has discovered that from the Indo-European base word "car" comes our modern derivation "ceramics." The Greek term "keramos" and Latin "cremo" were intermediate steps. The word means "to burn" earthy materials. The engineer may now add to polite conversation on the arts when the subject of Ming dynasty pottery is broached in the drawing room.

British Chemical Industry

(From our London Correspondent)

London, March 8, 1920.

INTEREST in the United Kingdom has centered upon the continued appearance of new capital issues and the adjustments and changes in policy which are occasioned by them. As was to be expected in view of the acquisition of the Castner-Kellner interests, Brunner Mond & Co. are now to purchase the business of Electro Bleach & By-Products, Ltd., of Middlewich, the latter firm being the only serious competitor in regard to electrolytic caustic soda. In addition it is rumored that as a logical consequence of Brunner-Mond's purchase of the government Haber plant at Billingham, it is intended to consolidate the firm's position in the nitrogen industry as far as possible. The dispute between Brunner-Mond and Lever Bros. in regard to the hydrogenation of fats and the manufacture of alkali was settled some time ago, and the transfer to Lever Bros. of Crosfield & Gossage's soap works is evidently intended to leave the soap industry in the hands of the one combination and the alkali industry in that of the other, probably with a mutual understanding in regard to the use of processes germane to both industries.

The alkali position will probably be affected in the future by the large quantities of sodium carbonate which will be available in British East Africa from the Magadi Soda Co. Operations on the branch railway to the deposits were suspended during the war, all such facilities being required for military operations. The railway has now been restored to the company, and it is stated that the first shipments of soda will be forthcoming in the summer of this year.

British Cellulose Co.

The British Cellulose Co., it will be remembered, erected large works at Spondon, near Derby, to manufacture cellulose acetate for airplane manufacture. The British Government provided about $9,000,000, secured upon the property, and after many vicissitudes, production commenced on a large scale some months before the end of the war. The company was adversely criticized, but largely exonerated by the special committee appointed to investigate its activities. Further capital being now required, the government was induced to exchange its debentures for profit-sharing preference shares, being part of the new issue. We thus have the curious situation of the government becoming a speculative shareholder in a chemical manufacturing company whose objects, as explained in the prospectus, go far beyond that of dope manufacture. One of the probable sources of profit indicated is that of artificial silk manufacture, and it is not surprising that much objection should have been taken to the government's course, not only by the artificial silk manufacturers, but also by the general public, which does not appreciate government competition with private enterprise.

British Manufacturers' Report

The report of the Association of British Chemical Manufacturers previously referred to[1] has been issued in abstract to the press, but it is still not available in full to the general public or to chemical manufacturers abroad, although it is hardly possible to prevent its indirect transmission. Missions such as that which issued the above report seem to give rise to some misunderstanding and suspicion. Thus, in the above case, a creditable report was evolved in the short space of three weeks' stay in Germany, yet adverse criticisms in regard to its contents have been made by those who did not take part and it has even been hinted that much additional useful information might have been included, which was either overlooked or withheld on account of uncertainty or self-interest. Again, in the case of the Color Users' Purchasing Commission, which visited Germany at the end of January, the principle of collective buying which its name indicates is not generally accepted (by the smaller users, at any rate) as the most advantageous one, and this in spite of the obvious lessons that could be drawn from such methods of co-operation in Germany before the war.

The Spirit of Co-operation

These internal dissensions are almost entirely due to the lack of co-operation in the British chemical industry as a whole and the ingrained distrust, jealousy and suspicions of the smaller manufacturers and, in some degree, of the various learned societies, which time and experience alone can eradicate. The fine chemical industry is a distinct sinner in this respect, and the leading firms in that industry show no signs of taking a lead in regard to co-operation, but maintain complete silence as to their future program. Signs are, however, not wanting that the smaller fine chemical manufacturers are discontented with the lack of capital of the industry as a whole and the aloofness of the larger manufacturers.

An attempt will probably be made to prevent the closing down of some of the smaller works, which will be inevitable if the industry as a whole is not placed on a secure foundation comparable with the American and continental organizations. As regards the various technical societies, it is understood that the scheme by which they will nearly all be accommodated in a central building on the lines of the Engineering Societies in the United States will shortly be formulated and that it will involve the raising of a very large fund. The matter is in the hands of the Federal Council of Learned and Scientific Societies under the guidance of Sir William Pope.

A more favorable moment could hardly have been chosen than the present in appealing for funds, when the value of science and chemistry in particular is at last being appreciated in some measure by the general public. The dinner of the Chemical Trade Association did not justify the hopes of its organizers, but when the older and more influential manufacturers proceed with their new and more comprehensive association, the position will become more stable. The functions and uses of a chemical merchant are not properly appreciated either by the general public or by the manufacturers, and in fact, the latter have lately been making strenuous efforts by direct and indirect propaganda to eliminate the merchant and middleman as far as possible. In doing so and in setting up their own special sales organizations, they overlook the fact that a merchant can dispose of the output of several factories more easily and at a lower cost than a single manufacturer can deal with his own output. While this policy may be satisfactory for the largest firms or for co-operative sales organizations in special lines such as sulphate of ammonia, the policy is unsound and may lead to retaliation from the merchants should they themselves decide to manufacture.

Ethylene and Propylene Chlorhydrins and Glycols From Oil Gas

Description of the Synthesis of Glycols From Ethylene and Propylene by Clorhydrating and Hydrolyzing—Content of Ethylene and Propylene in Oil Gas — Details Regarding Methods, Distilling and Hydrolyzing

By BENJAMIN T. BROOKS

THE chemical utilization of petroleum, that is, in ways other than direct combustion as fuel, readily suggests a series of latent or undeveloped possibilities. The present work is an effort to develop one phase of this problem.

Interest in the simpler chlorhydrins and glycols has been recently revived in connection with the substitution of glycols for glycerine in explosives and also in connection with the manufacture of ββ dichlorethyl sulphide, or the now well-known mustard gas. The Germans made their mustard gas from ethylene chlorhydrin, but in the Allied countries this method was superseded by the direct or sulphur chloride method.[1]

The simpler glycols have frequently been proposed as substitutes for glycerine but until quite recently a satisfactory method for their commercial manufacture has been lacking. In normal times the supply of glycerine available in the sweet lye from soap manufacture more than meets the demand for such material and the larger soap manufacturers are able to recover glycerine of good quality at a very low cost. However, it is possible that uses for the glycols may be found in which the glycols may possess certain advantages over glycerine. Ethylene and propylene glycols are much less viscous than glycerine and may therefore have a certain advantage over the latter in refrigeration systems, low freezing solutions and the like.

Several years ago A. M. Hough[2] showed that glycols can be smoothly nitrated to the corresponding dinitrates and that these glycol dinitrates may be mixed with nitroglycerine to form very low freezing mixtures. Hough seems to have been the pioneer of practical work in this field, although the glycol nitrates were made and described many years ago by Henry,[3] Champion,[4] Demjanow,[5] Nef[6] and others. Mathews, Strange and Bliss[7] have patented explosives containing nitrated 1,2 glycols compounded with nitrocellulose, infusorial earth, etc., and under the Jolicard patent[8] explosives containing nitroglycerine, together with nitrocellulose, nitroglycerine and nitrate salts, are said to have been manufactured industrially in Europe.

Other substances capable of lowering the freezing point of nitroglycerine and possessing explosive values of their own have been tried, for example glyceryl monochlorhydrin dinitrate[9] and glyceryl methyl ether dinitrate.[10] One objection which explosive manufacturers have repeatedly raised against the nitroglycols is their high volatility as compared with nitroglycerine, and their toxicity. Several patents on explosives containing nitroglycols have recently been granted to J. Barab.[11]

Ethylene and propylene glycols, as described in the earlier literature, are very hygroscopic liquids, considerably more volatile than glycerine. This tendency to evaporate causes flexible glue compositions containing glycol to become brittle. On the other hand, when added to tobacco, the natural resins present appear to retard the evaporation of the glycol.

Trimethylene glycol, or 1.3 dihydroxypropane, has also long been known and is obtained in commercial quantities as a minor byproduct in the manufacture of glycerine and is apparently formed from glycerine itself by fermentation. The total available supply of this material is, however, quite small.

The cheapness of chlorine under present conditions brings the manufacture of these glycols and chlorhydrins within the bounds of economic production. The following résumé indicates the methods thus far found successful and indicates also other possible methods.

Dihalides

In the older published work the dibromides were employed almost exclusively, on account of the ease of preparing them in the laboratory and the facility with which they are hydrolyzed or converted into esters. The chlorination of oil gas with the formation of Dutch liquid was first carried out by Faraday in 1825.[12] As pointed out by Armstrong and Miller,[13] "oil gas" has the same general composition, whether made from fatty or mineral oils. But the chlorination of ethylene to the dichloride, which is the kernel of the matter, was first carried out in 1795 by the four Dutch chemists from whom the dichloride gets its name of "Dutch liquid." Several recent patents on the subject refer to special methods of chlorination.[14]

[1] The preparation of mustard gas, or *ββ* dichlorethyl sulphide, from ethylene chlorhydrin was plainly indicated by the work of Victor Meyer and Clark, and involves treatment of aqueous ethylene chlorhydrin with sodium sulphide, concentrating or dehydrating the dioxysulphide thus formed and warming the latter with concentrated hydrochloric acid. It was perhaps fortunate that the manufacture of ethylene chlorhydrin, on a commercial scale, had not been perfected in any of the Allied countries, since by the development of the direct sulphur chloride process the Allies were able to reach a production capacity for mustard gas approximately thirty times that of the Central Empires. The author, with I. W. Humphrey,[15] has shown that the conversion of ethylene chloride to glycol proceeds readily when heated under pressure with methyl alcohol and an alkali formate, ethylene diformate being formed as an intermediate product. Aqueous carbonate or bicarbonate solutions at somewhat higher temperatures and pressures also give good yields, which process has been patented by Matter.[16]

Chlorhydrins

The conversion of ethylene and propylene chlorhydrins to the corresponding glycols may be effected by heating with aqueous bicarbonate or carbonate solutions. The best yields, about 85 per cent of the theory, are obtained by heating chlorhydrin solutions containing not over 20 per cent chlorhydrin with a slight excess of sodium bicarbonate in an autoclave to 110 deg. for about two hours. Hydrolysis of the chlorhydrin with evolution of carbon dioxide is quite appreciable at 70 deg. but by simply refluxing the chlorhydrin with bicarbonate solution the yield of glycol is about 50 per cent of the theory. This method, which has also been patented,[17] gives very much better yields than the older methods described in the literature by Henry and others. Typical results of this method are described below.

Oxidation of olefines to glycols by cold dilute permanganate solution is frequently given in text books as a general method, but as the yields are seldom more than 5 per cent of the theory and the materials costly, this is clearly out of the question as a commercial method. However, catalytic oxidation by oxygen or air through an intermediate oxygen carrier, as is suggested by the work of Hofmann and Schneider[18] on oxidation in the presence of a very small quantity of osmic acid, would be economically sound should suitable catalysts be discovered.

Raw Materials

Oil gas, containing 35 to 45 per cent olefines, still gases from petroleum cracking stills and containing 10 to 12 per cent olefines, and ethylene made by the decomposition of alcohol are the only sources of ethylene and propylene of practical importance. The hydrogenation of acetylene to ethylene has never been carried out on a large scale, nor by any method having great promise of industrial success. One possible source of these simpler olefines is suggested by the large quantities of ethane and propane which are available in natural gas, or more specifically, in the very light fractions ordinarily permitted to escape from casing head gasoline which has been condensed under considerable pressure.

Ethane and propane are partially converted into ethylene and propylene by heat and the monochlorides are almost quantitatively decomposed to the corresponding olefines by passing the vaporized chlorides over pumice impregnated with barium chloride and heated to 400 to 450 deg. C.[19]

The manufacture of very pure ethylene by the catalytic decomposition of alcohol, together with a little steam, in contact with kaolin at 400 to 500 deg. has been carried out on a large scale with excellent yields and low cost by the U. S. Chemical Warfare Service.[20]

[19] This has not been carried out on a large scale.

[20] Dorsey, *J. Ind. Eng. Chem.*, vol. 11, p. 288 (1919); Engelder, *J. Phys. Chem.*, vol. 21, p. 676 (1917); Hough, U. S. Pat. 1,206,222, employs $Al_2(SO_4)_3$ on an inert material at 350-400 deg. Of. also Norris, *J. Ind. Eng. Chem.*, vol. 11, p. 821 (1919).

Although oil gas has been manufactured for a great many years and under widely varying conditions, little or no attention has been given to its composition with respect to the different olefines which it contains, as these are commonly determined together as "illuminants."

The data given in Table I indicate approximately the composition of oil gas, with respect to ethylene and propylene, as made in commercial practice in a gasifying apparatus of the Pintsch type. The temperatures given are those at the beginning and end of the gas-making periods. From the work of Whitaker, Rittman and Alexander, it is certain that the percentages noted are not the equilibrium values for these temperatures. Also from the work of Hall it is recognized that comparatively slight variations in temperature produce large changes in the composition of the resulting gas. The data given are merely those obtained from gas made by commercial practice.

TABLE I. PER CENT ETHYLENE AND PROPYLENE IN OIL GAS[21]

Temp. Deg. C.	Higher Olefines, Per Cent	C_3H_6 Per Cent	C_2H_4 Per Cent	Total Olefines Per Cent
805—650	1.4	18.6	16.3	36.3
660—535	1.6	19.0	18.3	38.9
635—535	2.4	22.4	12.5	37.3
625—535	2.6	22.6	13.7	38.5
615—425	3.8	25.7	12.0	41.5

The data in Table II show the composition of the oil gas obtained by rapidly passing the oil vapors, under pressure, through tubes heated to certain definite temperatures in an apparatus of the Hall type.

TABLE II. COMPOSITION OF OIL GAS MADE IN TUBES MAINTAINED AT DEFINITE TEMPERATURES

Temperature, deg. C	600	650	700	730
Pressure, lb	57	72	83	95
Ethylene, per cent	19.3	19.0	17.7	17.5
Propylene, per cent	28.0	28.4	23.9	20.0
Higher olefines, per cent	3.2	4.2	3.5	3.1
Total olefines, per cent	50.5	51.6	45.1	40.6

Although the per cent of total olefines is somewhat less at the higher temperature, the net yield is considerably greater on account of the larger volume of gas produced, as is indicated by the figures given in Table III.

TABLE III. PER CENT OIL GASIFIED IN HALL TYPE APPARATUS AT DIFFERENT TEMPERATURES

Temperature, Deg. C.	Per Cent Gas	Per Cent Ethylene and Propylene
605	17.7	47.9
625	26.6	46.1
645	37.6	44.9
665	40.0	43.7
685	40.8 (?)	42.6
705	48.7	39.5
725	66.6	38.5

It will be noted in the analysis quoted that the higher olefines commonly represent about 4 per cent by volume of ordinary oil gas and may be present to the extent of 10 per cent in a gas made at low cracking temperature and containing about 52 per cent total olefines. In order to limit the chlorhydrins and glycols to ethylene and propylene (incidentally removing[22] also benzine and

[21] The above values were obtained by absorbing the higher olefines in 70 per cent sulphuric acid (Hempel pipette), the propylene in concentrated sulphuric acid sp.gr. 1.84 at room temperature, and the ethylene in bromine water. According to Nef (*Liebig's Ann.*, vol. 318, p. 1901) these olefines may be quantitatively separated and determined in this manner. In the author's opinion, this method is much more accurate than that of fractionating the mixture of olefine dibromides, and is very much more rapid.

[22] The resulting liquid is practically identical with the light "drips" which it is customary to separate in the manufacture of Pintsch gas.

gasoline vapors), it is necessary to remove the higher olefines, which in this work was done by cooling and compressing to 175 to 200 lb. pressure.

Ethylene and Propylene Chlorhydrins

The problem of manufacturing these chlorhydrins proved not to be particularly difficult, once the discovery was made that the addition of hypochlorous acid to ethylene and propylene takes place at ordinary temperatures in very dilute aqueous solution with extreme rapidity.

Some of the older work, for example that of Wurtz and Carius, was misleading in this respect. They permitted ethylene to be slowly absorbed by a fairly strong solution of hypochlorous acid during long standing in the dark at room temperature and atmospheric pressure. The chief factor retarding the actual preparation of the chlorhydrins appears to be the solution of the gas in the aqueous solution. Thus we have found that it is not necessary to employ solutions more concentrated than 0.10 per cent total hypochlorites. Conditions which promote the solution of the gas in the aqueous solution, as for example agitation or moderate pressures, and which should not appreciably affect the rate of the reaction with HOCl, very greatly accelerate the formation of chlorhydrin.

The Preparation of Hypochlorous Acid

In the earlier work on chlorhydrins the method of preparing hypochlorous acid usually was the well-known reaction between mercuric oxide and chlorine water.[23] The method of adding a weak acid, such as boric acid, to a hypochlorite in dilute aqueous solution was carried out by Lauch,[24] Bamberger,[25] Baeyer and others. A more satisfactory method is that of Wohl and Schweitzer,[26] which consists in passing chlorine into a cooled solution of sodium carbonate or bicarbonate. Weyl also recommends this method.[27] H. V. Walker has patented a variation of this method, which consists in adding an excess of sodium bicarbonate to an alkaline solution of sodium hypochlorite.[28]

Although quite concentrated solutions of sodium hypochlorite are quite stable when sodium hydroxide is in excess, as shown by Muspratt and Smith,[29] the decomposition of such concentrated hypochlorite solutions is so rapid the instant free hypochlorous acid is present that good yields of chlorhydrin are not obtainable from them. The gradual liberation of free HOCl, in the presence of ethylene and propylene, by weak acids such as CO_2 and boric acid, were tried but the yields of chlorhydrin based on the original quantity of hypochlorite were only 25 to 30 per cent of the theory. Somewhat better results were obtained by liberating HOCl from bleaching powder by CO_2 in the presence of ethylene and according to Norris[30] the Germans made ethylene chlorhydrin, for mustard gas manufacture, in this manner.

The continuous process described below gave much better results, however, and work with concentrated hypochlorite solutions was abandoned.

McElroy[31] has patented a novel and ingenious method of manufacturing chlorhydrins from ethylene or oil gas, which consists in passing the olefines into a mixture of steam and chlorine. According to the author's experience, on a large experimental scale, large proportions of highly chlorinated oily products result under these conditions. The apparatus required is large and comparatively costly. Typical results are as given in Table IV.

TABLE IV. TREATMENT OF OIL GAS WITH STEAM AND CHLORINE

	I	II	III
Total gas used, cu.ft.	1,920.00	1,730.00	2,010.00
Gas rate, cu.ft. per hr.	240.00	216.00	251.00
Total chlorine, lb.	53.40	51.60	52.20
Pounds chlorine to 1 lb. chlorhydrin.	2.27	2.40	1.86
Dilute chlorhydrin distillate, lb.	582.00	312.00	545.00
Steam, total lb.	1,460.00	1,364.00	1,477.00
Per cent chlorhydrin in distillate.	4.05	6.91	5.15
Steam, lb. to 1 lb. chlorhydrin.	62.00	63.00	52.80
Total lb. chlorhydrin.	23.50	21.50	28.00

From what is known of the properties of hypochlorous acid it seemed probable that better yields would be obtained by working with cold aqueous solutions. Considerable careful work on the system

$$Cl_2 + H_2O \leftrightharpoons HOCl + HCl$$

has shown that the relative amount of hypochlorous acid which is present at any one moment is quite small. But, as shown by Gomberg,[32] the velocity of the combination of HOCl and ethylene is so much greater than that of the formation of ethylene chloride that very excellent yields of ethylene chlorhydrin may be obtained by passing chlorine and ethylene into cold water, with vigorous agitation to promote the solution of the two gases.

This operation is readily carried out with oil gas in a suitable apparatus, i.e., one in which the cold reaction solution does not have to be pumped or circulated. The apparatus developed by the author for making chlorhydrin was of the liquid circulating type, and in order to minimize the corrosion difficulties the free HCl in the solution was neutralized by soda ash, sodium bicarbonate or borax, although, as shown by Gomberg, the salt which thus accumulates in the solution retards the production of chlorhydrin. The general plan of the apparatus employed is shown in Fig. 1. In a small apparatus of this type, in which the reaction tower measured 12 ft. x 12 in., it was shown that the production of chlorhydrin was fairly rapid until the solution contained about 5.0 per cent chlorhydrins. Thus in one experi-

ment lasting 14 hr. the concentration of chlorhydrin in the solution at the end of 7.5 hr. was 5.0 per cent, but in the next 6.5 hr. only increased to 6.65 per cent, although chlorine and oil gas were supplied at the same rate and all other conditions, pressure and temperature, remained the same. Also it was noted that propylene reacted more readily than ethylene, as was indicated by the fact that the proportion of ethylene to propylene was much greater in the exit gases than in the gas supplied to the hypochlorous acid solution; for example, a gas contain-

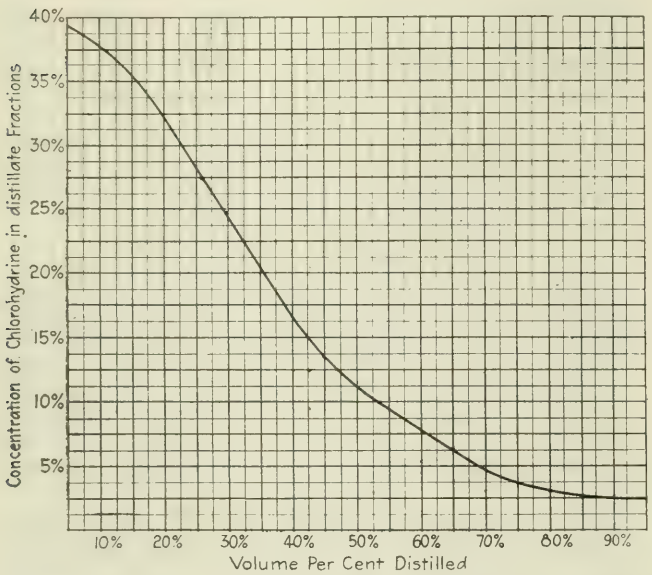

FIG. 2. DISTILLATION BEHAVIOR OF ETHYLENE CHLORHYDRIN ABOUT 24 PER CENT BY WEIGHT SOLUTION

ing 15.7 per cent ethylene and 10.2 per cent propylene after passing through the apparatus showed 3.4 per cent propylene and 3.6 per cent ethylene.

After a large number of experimental runs, the data of which it is not necessary to include here, a larger cement lined apparatus was erected, of dimensions permitting the employment of about 600 lb. of chlorine and 1,000 gal. of solution per batch. The circulating solution was cooled to keep the temperature practically constant at 15 deg. C. The following results, obtained in the larger apparatus, under 75-lb. gas pressure and using oil gas containing 34 to 36 per cent total ethylene and propylene, are representative:

TABLE V. ETHYLENE AND PROPYLENE CHLORHYDRINS FROM OIL GAS AND COLD AQUEOUS HOCl

Exp. No.	Chlorine, Lb.	Gas, Cu.Ft.	Sodium Bicarbonate, Lb.	Olefines Used, per 100 Cu.Ft. Gas	Chlorhydrin Per Cent	Chlorhydrin Lb.
I	415	3,470	607	32.6	4.55	407
II	424	4,290	600	28.8	4.70	425
III	531	5,060	650	29.4	5.30	488
IV	540	4,530	700	26.5	4.65	430
V	681	6,040	750	28.4	7.75	561

Sodium bicarbonate may be replaced by soda ash with equally good results, but the solution must be cooled more strongly to maintain the temperature at 15 deg. on account of the heat of solution of soda ash and the larger amount of heat developed by neutralization.

Aqueous ethylene chlorhydrin is not affected by free chlorine at 0 deg. Propylene chlorhydrin is only very slowly acted upon by free chlorine at this temperature. At about 95 to 100 deg. and in the presence of steam small quantities of very acrid irritating substances are produced, probably chloracetaldehyde and chloracetone.[33] Gomberg[34] has noted the distillation behavior of dilute ethylene chlorhydrin solutions. Fig. 2 indicates the distillation behavior of an ethylene chlorhydrin solution, 24 per cent by weight, the first fractions consisting of the constant boiling mixture containing 37.5 per cent chlorhydrin. Fig. 3 gives the distillation behavior of the oil gas chlorhydrins, ethylene and propylene chlorhydrins being present in about equal amount, the aqueous solution taken for distillation containing 24 per cent by weight of the chlorhydrins. The same figure also shows (curve I) the effect of saturating a solution of the same concentration with common salt. On saturating with salt two layers are formed, the upper layer containing most of the chlorhydrin, and it will be noted that the distillation of the saline chlorhydrin solution more nearly approaches that of a pair of two mutually insoluble liquids. When the initial solution contains more chlorhydrin than corresponds to the constant boiling mixture, the latter will of course distill first and finally anhydrous chlorhydrin will distill, as indicated in Fig. 4.

As the work described in the present paper was carried out under industrial conditions and primarily for the purpose of making the mixed glycols, no attempt was made to distinguish between the two isomeric propylene chlorhydrins. Michael,[35] Henry,[36] Smith[37] and others have shown that on the addition of HOCl to propylene the resulting chlorhydrin mixture contains mostly chlor-β-hydroxypropane.

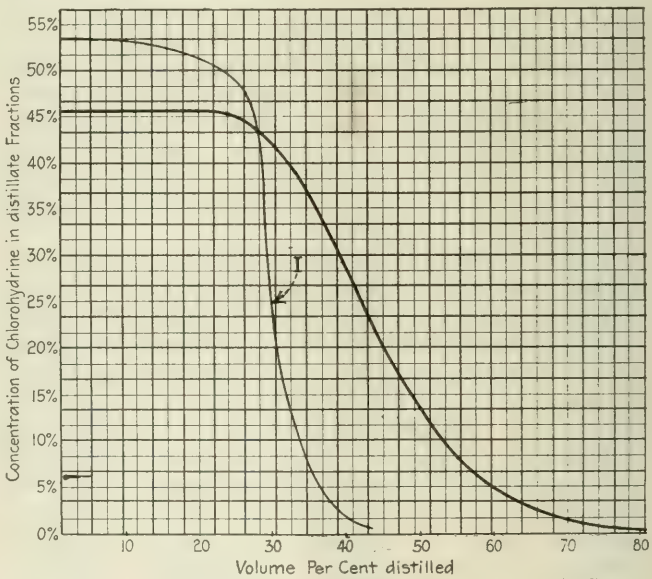

FIG. 3. DISTILLATION BEHAVIOR OF OIL GAS CHLORHYDRINS

That anhydrous chlorhydrins possess valuable solvent properties is well known, but the ease with which they hydrolyze, with the formation of hydrochloric acid, greatly restricts their field of usefulness. The hydrolysis of an 8 per cent solution of ethylene chlorhydrin at 95

[33]The relative stability of ethylene chlorhydrin to chlorine is of interest as indicating the influence on the $-CH_2OH$ group of a chlorine atom attached to the adjacent carbon atom. It tends to confirm also the generally accepted view that when ethyl alcohol is chlorinated the $-CH_2OH$ group is first attacked to form CH_3CHO, which then immediately is chlorinated in the methyl group, finally to chloral.

deg. (maintained at 95 deg. in a Freas oven) is graphically indicated in Fig. 5. The hydrolysis of propylene chlorhydrin, 9.4 per cent, or equivalent to the concentration of the ethylene chlorhydrin solution, is also shown in Fig. 5.

The use of chlorhydrins as solvents for cellulose acetate has been patented by Lindsay and by the von Hayden Chemical Co.[38] Glycol mono-acetate is said to affect favorably the physical properties of cellulose acetate films and also increases the ability to dye.[39]

Although the simpler chlorhydrins have frequently been salted out with potassium carbonate, it was apparently not observed until comparatively recently that by merely warming the aqueous solutions with alkali carbonates or bicarbonates, glycols are produced. Evans[40] stated that the alkali carbonates converted these chlorhydrins into the corresponding alkylene oxides, but did not actually isolate or identify them. On heating aqueous solutions of ethylene or propylene chlorhydrins and sodium bicarbonate to 65 deg., marked evolution of carbon dioxide takes place. By refluxing with sodium carbonate or bicarbonate and carefully working up the aqueous solution for glycol, yields of 44 to 48 per cent of the theoretical are obtained. The remainder is converted into ethylene and propylene oxides which pass off with the carbon dioxide. The older statements are therefore partly correct. By carrying out the reaction in an autoclave and heating to 105 to 110 deg. C. for 2 hr., yields of glycol equivalent to about 90 per cent of the theory are obtained. The remainder is a tarry material which cannot be distilled at 10 mm. without decomposition and is probably identical with the non-distillable

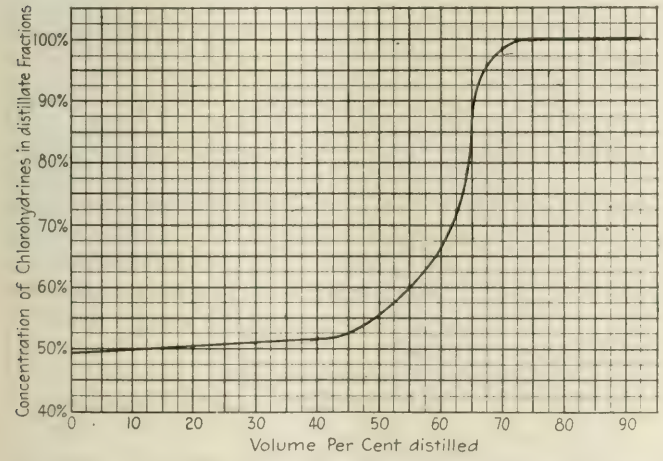

FIG. 4. DISTILLATION BEHAVIOR OF 70 PER CENT ETHYLENE AND PROPYLENE CHLORHYDRIN MIXTURE: 30 PER CENT WATER

amorphous substance obtained by Wurtz by treating ethylene oxide in aqueous solution with alkali.[41]

It might conveniently be noted here that the yields of alkylene oxides obtainable from the simpler chlorhydrins depend upon the concentration of caustic alkali and the removal of the volatile oxides from the reaction mixture as rapidly as possible. Thus by dropping concentrated, nearly anhydrous (90 per cent) ethylene chlorhydrin upon solid caustic soda and stirring slowly to break up the crusts of sodium chloride, a yield of 80 per cent of the theory of ethylene chlorhydrin is obtained. When an equivalent quantity of 10 per cent caustic soda is employed no ethylene oxide can be obtained and evaporation of the solution yields an amorphous material probably identical with Wurtz's product.

Ethylene chlorhydrin gives nearly theoretical yields of the glycol. A typical result is the following: Twelve kilos of a solution containing 6.22 per cent ethylene chlorhydrin was treated with 835 g. sodium bicarbonate and heated for 1 hr. at 105-110 deg. C. in an autoclave. From the resulting solution 536 g. anhydrous ethylene glycol was obtained, which is equivalent to 93.5 per cent of the theoretical yield.

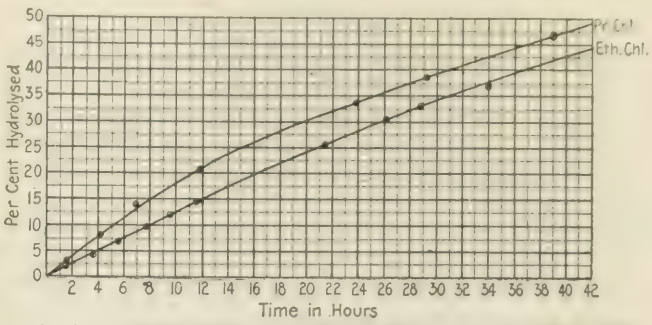

FIG. 5. HYDROLYSIS OF ETHYLENE AND PROPYLENE CHLORHYDRIN SOLUTIONS AT 97 DEG. C.

An aqueous solution containing 20.8 per cent ethylene and propylene chlorhydrins, from oil gas, the two chlorhydrins being present in nearly equal amounts, gave a slightly lower yield. Three kilos of the chlorhydrin solution, equivalent to 625 g. anhydrous chlorhydrins, and 570 g. sodium bircarbonate, yielded 403 g. glycol, or about 81.5 per cent of the theoretical. Slightly lower yields of glycol were obtained when sodium carbonate was substituted for sodium bicarbonate. To 300 g. anhydrous chlorhydrin mixture 5.5 liters of water and 180 g. sodium carbonate were added and the mixture heated for 1 hr. at 105 deg. From the solution 176 g. glycol was recovered, equivalent to 74.2 per cent.

The above processes have been carried out on a semi-industrial scale. The autoclave pressures, due chiefly to the carbon dioxide liberated, are not excessive, ranging from about 100 to 150 lb., depending upon the concentration of the solutions employed and the relative volumes of liquid and air space in the autoclave. The recovery of glycol from the saline aqueous solutions is very much the same as in the case of glycerine, except that the two glycols are much more volatile than glycerine, ethylene glycol boiling at 197.5 deg. C. and propylene glycol boiling at 188 deg. The separation between water and the glycols on distilling is therefore not so sharp as in the case of glycerine. In order to obtain water-white anhydrous glycol free from decomposition products it is necessary to distill *in vacuo*, and on a large scale the same type of still as is employed for glycerine serves admirably for the glycols. On account of the large quantities of salt in the glycol reaction mixture it is preferable to concentrate to a glycol-water ratio of about 70 : 30, when nearly all the salt is deposited. The filtered glycol may then be distilled *in vacuo* without difficulty, which practice of course is not novel, closely following the procedure common with glycerine liquors.

The author desires to express his indebtedness to Dr. J. B. Conant and Dr. James R. Norris of the U. S. Chemical Warfare Service for their many suggestions and advice.

Balanced Reactions in Steel Manufacture*

An Argument That the Oxidation of Iron During Melting Is by Steam, That Iron Oxide Is Soluble in Molten Iron, and That Silicon Is Reduced From an Acid Slag by Carbon—Observations on the Composition of Gas in Blow-holes and in Solution in Solid Steel

BY ANDREW McCANCE

THERE is no satisfactory theory of the reactions which take place in the open-hearth furnace during the manufacture of steel. A general view presents several separate groups of facts with independent explanations which have not yet been connected, one with the other, in logical sequence. In this paper a rough outline is put forward of these facts considered from the standpoint of physical chemistry and of well-established theoretical principles, and the connection which exists between the final quality of the solid steel and the antecedent conditions during manufacture is traced with special reference to the contained gases. Though the author deals mainly with the open-hearth process, much of course is applicable to the other processes of steel manufacture, where the general conditions are similar in principle though different in detail.

MELTING

During the melting period in the furnace the metal is in contact with a variety of gases, such as CO_2, water vapor, nitrogen, as well as unburned oxygen and CO, with which it can react under appropriate conditions. There is one fact which guides us, however, in determining the dominant reaction from among the many complex reactions possible, and that is, that as the average temperature of melting gets lower there is greater oxidation of the scrap and consequently more FeO in the slag. Every steel-smelter knows that with a cold heat there is a more open slag and a greater tendency to go on the boil without ore than when the charge is melted hot. In terms of slag analyses, the following are two typical cases:

	FeO	SiO_2
Cold heat	36.3	36.4
Hot heat	20.8	45.0

The higher the temperature is, the rate of oxidation of the iron gets less, and possible reactions may be considered in the light of this fact.

1. The direct oxidation of the iron by the air is ruled out of account at once, since it is known that the rate at which scale forms on an iron surface increases greatly with temperature. Direct oxidation does, of course, take place, but it is not the main cause of oxide formation, but only a secondary one.

2. Oxidation by CO_2 is possible in two ways

$$Fe + CO_2 = FeO + CO - 2.3 \text{ cal.}^1 \quad (1)$$

$$3Fe + 4CO_2 = Fe_3O_4 + 4CO - 1.4 \text{ cal.} \quad (2)$$

These are balanced reactions, of which the first has been worked out fairly fully, and the composition of the gases which are in equilibrium with iron and ferrous oxide at different temperatures is as follows:

Temp., Deg. C.	CO Per Cent	CO_2	Ratio CO:CO_2
550	54	46	1.16
650	58	42	1.38
750	61	39	1.56
850	68	32	2.12
900	71.5	28.5	2.51

In Appendix II the author has calculated what the composition would be at higher temperatures, and finds that at 1,500 deg. it would be CO = 92.4, and CO_2 = 7.6, so that if the iron was in contact with any gas containing more than 7.6 per cent CO_2 it would be oxidized. But the burned gases in a steel furnace contain very little CO, and consequently reaction is possible. But the higher the temperature the greater will be the difference between the gases in contact and the gases in equilibrium, so that the higher the temperature the greater the oxidation.

This result can be obtained in another way by the Le Chatelier principle, for on giving the reaction heat, it must proceed so as to absorb heat. It has a negative heat of reaction, and must in consequence proceed from left to right, that is, more FeO will be formed. Exactly the same result is obtained with the second reaction, so that neither of these can be the dominant reaction during the melting period.

3. The action of steam on iron gives

$$3Fe + 4H_2O = Fe_3O_4 + 4H_2 + 38.5 \text{ cal.}^2 \quad (3)$$

With increasing temperature the amount of hydrogen gets less, and the same result follows from the Le Chatelier principle, so that the rate of oxidation is in accord with the slag condition as observed in practical working.

If the loss due to scaling is to be minimized and as little of the charge as possible is to find its way into the slag as oxides, three conditions have to be observed:

1. Melt down rapidly.
2. Melt down at high temperature.
3. Have a low steam content in the burned gases.

Nos. 1 and 2 give together hot and quick working. It is often held that during the melting-down period the temperature of the bath must be constant, since there is solid and liquid metal in contact; but this is only true if there is equilibrium, which never holds for steel-melting furnaces. So long as the liquid bath is growing at the expense of the solid scrap there is a difference in temperature between them, and the quicker the rate of melting the greater must this difference be. Pyrometer observation shows, in fact, that the temperature of the liquid bath is rising steadily during the melting period.

The presence of steam in the burned gases arises from the combustion of the hydrogen in the producer-gas together with any undecomposed steam which has passed through the producer. The composition of the gas has therefore a direct bearing on the working of the furnace and on the loss of metal due to scaling.

*A paper presented in a symposium on "The Occlusion of Gases by Metals," *Transactions* of the Faraday Society, vol. 14, p. 213.

[1]Baur and Glässner, *Z. physik. Chem.*, 1903, vol. 43, p. 354.

[2]Deville, *Liebig Ann.*, vol. 156, p. 76; Preuner, *Z. physik. Chem.*, 1904, p. 385.

As a result of this reaction the steel has an opportunity of absorbing hydrogen. There is no experimental evidence as to the extent of the solubility of hydrogen in iron in the liquid or solid state. Baraduc-Muller[3] found that the rate of evolution of hydrogen during solidification was not much greater than the rate of evolution after the steel had become completely solid. If there is little difference in the solubility in the liquid and in the solid state, it is unlikely that hydrogen is ever the cause of blow-hole formation in steel.

Boiling Period

After melting, the liquid bath has a covering of slag containing FeO and other oxides (which, however, take no part in the subsequent reactions), together with silica. Independently of how these constituents are combined one with the other, the slag can be regarded as an impure solution of ferrous oxide in silica. The addition of iron ore increases the strength of this FeO solution, and since there is no contrary evidence it must be inferred that iron oxide so added cannot act on the steel bath without first going into solution in the slag. The first action of the slag is to oxidize any Si and Mn in solution in the liquid metal; but these reactions need not be considered here, since they do not give rise to gaseous reaction products. After they have been removed, however, the carbon is attacked according to the equation

$$FeO + C = CO + Fe \qquad (4)$$

The FeO is derived from the slag, but there are many reasons for believing that the reaction is by no means confined to the surface layers of metal, but takes place equally throughout the whole mass of liquid. If the slag is scraped off during the boiling period, the metal still goes on boiling vigorously, and can do so for a considerable time, although there are only traces of slag in contact with the steel. Clean pieces of Swedish charcoal iron containing 0.16 per cent carbon lose all their carbon when melted in a magnesia crucible in an electric vacuum furnace.[4] When a local area in the bottom of an open-hearth furnace gets bad, the boil takes place much more vigorously over that area than elsewhere, and the slag may be projected some distance above the general level through the energetic action. Such facts point to the CO being liberated simultaneously throughout the mass of metal, and since the carbon is in solution, it entails that the FeO must also be in solution in the steel.

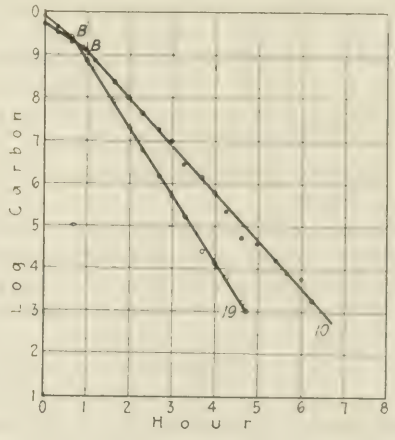
On this assumption the FeO is divided between two solvents, the slag and the steel, and the application of the partition law to such a system indicates that the concentration of the FeO in the steel must bear a constant ratio to that of the slag if the molecular condition of both solutions be the same. If FeO in the steel be removed from solution, then more FeO will pass from the slag into the steel, until a balance is once more obtained, and if the FeO be continuously removed, then a continuous flow of FeO will come from the slag and will endeavor to replace the loss. If no addition of FeO be made to the slag (in the form of iron ore), then the percentage content will fall continuously.

The mechanism of the carbon reduction in the open-hearth process can now be understood, for as the ore is added to the slag it dissolves as FeO, which is transferred in solution to the bath, and reduced by the carbon there with the production of CO. The reaction will follow the laws of chemical kinetics, so that, stating the concentration of the FeO in the slag as C_{FeO}, the concentration in the steel will be aC_{FeO}, where a is the partition coefficient. If C_C and C_{CO} stand for the corresponding concentrations of the carbon and the carbon monoxide, the reaction velocity will be

$$\frac{dx}{dt} = K(aC_{FeO} - x)(C_C - x) - k(C_{CO} - x) \qquad (5)$$

where K and k are constants.

The carbon monoxide which is first given off dissolves in the steel, but whenever the steel becomes saturated the excess gas will escape into the atmosphere. This is the commencement of the boil. The steel from this moment is therefore saturated with gas, so that the CO term in equation (5) can be neglected. On integrating, this equation takes the usual logarithmic form, and the log of carbon against time should plot a straight



line. It is to be remembered at this stage that this will only be true if no external addition is made to the FeO after the reaction starts—that is, if no ore is added to the charge after the boil commences. The accompanying figure gives curves taken from results obtained by the author. Samples were taken every 20 min. during the course of two acid open-hearth charges from the time the metal was melted until it was tapped out. It will be seen that the straight line fits the points surprisingly well, considering that in a melting furnace under steelworks conditions it is impossible to keep other complex influences constant, as the theory assumes.

The curves are interesting in another way, for each really consists of two parts. The first part relates to the loss of carbon before the boil commences, when the bath still contains some silicon and manganese. The commencement of the boil is marked by a distinct angle between the two parts of the curve, and the rate of loss of carbon when the other elements are present is much less than when they are absent.

As the carbon in the bath gets less, the rate at which it is being reduced also gets less, until it ultimately becomes of the same order of magnitude as the rate of the reverse reaction brought about by the presence of the CO. When it becomes equal to the latter, then equilibrium is established and no further carbon is oxidized. When this takes place, equation (5) reduces itself to

$$\text{Constant } \frac{K}{k} = \frac{C_{CO}}{aC_{FeO}\,C_C} \qquad (6)$$

[3] *Jour. Iron and Steel Inst., Car. Res. Mems.*, 1914, p. 216.
[4] Yensen, *Bull. Illinois Univers.*, No. 72, p. 41.

How far the attainment of equilibrium is possible in a melting furnace is a difficult question to decide. The carbon, for one thing, is never constant, but is always dropping slowly, and the time element in practical working necessitates the adoption of other means for controlling the oxides in solution. But the conditions, however they may vary, are always trying to approach equilibrium, and alterations in the external conditions will have the same effect whether it is attained or not.

Since the steel is saturated, the upper term will remain constant in equation (6), and so the lower the carbon in the steel at the final stage, other things being equal, the higher the amount of FeO and vice versa, which accounts for the fact that mild steels are more difficult to deoxidize than higher carbon steels made under the same conditions.

Supposing lime is added to a slag which is in equilibrium with the metal underneath, then the FeO concentration of the slag is reduced and the metal is no longer in equilibrium, but contains excess FeO which will act on the carbon available until equilibrium is once more attained. For this reason CaO can replace ore with advantage toward the end of the boil, but it is obvious that this action cannot take place at the beginning of the boil, since the effect would then be directly opposite and it would retard oxidation. Any diluent, such as manganese ore, magnesia, etc., would act exactly in the same manner.

The influence of temperature is very important, and in the author's opinion it is the one method of control which is neglected in practical steel-making. It is not sufficient to tap a charge which leaves no ladle skull and possesses an excess of heat which is irregular and varies from charge to charge. Much more than that is implied by "temperature control." It is the production of charges of steel which have been worked in the furnace, and which have been cast with a constant and known amount of superheat over the temperature of solidification.

In Appendix I the calculations are given which show that for a variation of 50 deg. in the finishing temperature a decrease of more than 33 per cent is possible in the amount of FeO which the steel carries in solution. The author has already shown the great influence which this fact has on the number of non-metallic inclusions present in the finished steel.[5] The reduction in the FeO content of the steel with rising temperature reacts correspondingly on the slag, with the well-known result of thickening it. High temperature working gives siliceous slags.

Reduction of Silicon

With a highly siliceous slag in contact with iron and carbon, reduction of the silica may take place in two possible ways:

$$SiO_2 + 2C = Si + 2CO - 122 \text{ cal.} \quad (7)$$

$$SiO_2 + 2Fe = Si + 2FeO - 51 \text{ cal.} \quad (8)$$

and in both an increase in temperature will lead to a greater reduction and the formation of more silicon.

From the results of a large number of estimations the author has found that in acid open-hearth working the reduction of silicon during the finishing stages, when the carbon is in the region of 0.15 to 0.20 per cent, is practically negligible. It is within the limits of chemical error. In acid electric-furnace work, on the other hand, it is quite appreciable, and it is possible to reduce 0.2-0.3 per cent direct from the slag. In crucible melting, the killing of the melt results from the reduction of the silica of the clay pot, but crucible charges are usually high in carbon, and it is much more difficult to kill low carbon charges in this manner. The experiments of MacWilliam and Hatfield[6] showed that this reduction may be brought about in open-hearth furnaces, but it is noticeable in their figures that when reduction takes place the carbon is about 0.40 per cent.

It is fairly evident, therefore, that it is the carbon which reduces the silica and not the iron. The reverse reaction in equation (8) is important when additions of silicon are made later for deoxidation purposes.

Manganese behaves similarly, and need not be considered separately.

Carbon Monoxide

The presence of CO in solution in iron entails a further reaction with the FeO

$$FeO + CO = CO_2 + Fe \quad (9)$$

a reaction which has been studied over a considerable range by Baur and Glässner[7] for solid Fe and FeO. Their results, however, will not enable us to arrive at quantitative conclusions regarding the equilibrium of the same materials when they are in a state of solution. Qualitative deductions in accordance with experimental facts can, however, be made. This equilibrium is independent of pressure, and the ratio of $CO:CO_2$ under reduced pressure is therefore constant. This is shown by the results of Baraduc-Muller[8] in the composition of gas drawn off an ingot in four periods between the time of casting and the solidification of the metal:

No.	CO	CO_2	Ratio $CO:CO_2$
1	43.2	5.2	8.3
2	56.8	4.0	14.2
3	40.8	4.8	8.5
4	24.8	2.8	8.8

Excepting No. 2, the constancy is extremely good when the difficulties of the experiment are remembered.

A lowering of the temperature of working greatly decreases the ratio (see Appendix II). Thus in cast iron[9]

Cast. Temp.	Ratio $CO:CO_2$
1,428	30.2
1,348	13.7
1,264	7.2

The bearing which this has will be considered in the next section.

The Formation of Blow-Holes

It is a general law that the solubility of gases in liquids increases as the temperature is lowered, but at the freezing point the solubility is much less in the solid state than in the liquid condition. As a result, all gases will show strongly the effects of primary segregation—that is, the concentration of the solution in the last portions to solidify. If during the progress of this concentration the limit of solubility is reached, then the excess gas will escape and blow-holes will be formed. At the finishing stages in the open-hearth furnace, as previously explained, the steel is saturated with CO and the amount of gas will depend only on the temperature. If this is constant, then all steels will start with the same amount of gas in solution. Starting, then, with a quantity of liquid steel containing CO and CO_2, and

[5] *Journ. Iron and Steel Inst.*, 1918, part 1, p. 289.

[6] *Ibid.*, 1902, part 1, p. 54.
[7] *Z. physik, Chem.*, 1903, vol. 43, p. 461.
[8] *Jour. Iron and Steel Inst., C. S. M.*, 1914, p. 216.
[9] *Jour. Iron and Steel Inst., C. S. M.*, 1916, p. 66.

neglecting for the moment all other reactions except (9), cooling will result in more CO_2 being formed at the expense of the CO. But the steel in the solid state may have a very limited solubility for CO_2, and if this be exceeded, blow-holes will be formed at the instant of solidification. The formation of blow-holes not only depends on the quantity of dissolved gas but also on the variety of gas. No attention has hitherto been paid to this possibility, and to explain all the peculiarities in the relations between these gases and steel it is only necessary to assume that steel in the solid state has a much greater solubility for CO than for CO_2.

When equilibrium is established according to equation (9)

$$K = \frac{C_{CO_2}}{C_{FeO} \cdot C_{CO}}.$$

When there is much ferrous oxide in solution, the ratio CO_2:CO will be correspondingly great, and when the steel solidifies, if the amount of CO_2 is greater than the metal can hold in the dissolved state, blow-holes will be formed. If on the other hand the ferrous oxide be removed, the amount of CO_2 will shrink until the ratio CO_2:CO corresponds to give the correct value of K, and on solidification the saturation limit may never be attained. It is important to notice that the total volume of gas (expressed as c.c. per g. of metal) may remain quite unaltered by the reduction of the FeO, so long as direct reduction of the gases does not take place. How well this accords with the experimentally determined volumes of gas by different observers will be seen by the following results. Boylston,[10] using all the well-known deoxidizers, found

	C.c. per 100 g.
Average for deoxidized metal	126
Average for oxidized metal	125

Goerens,[11] using quite a different method for the estimation of the gas, gives the mean of two charges in a basic open-hearth furnace, the samples being taken from the bath before and after deoxidation

	C.c. per 100 g.
Average before deoxidation	67
Average after deoxidation	88

Baker,[12] from two similarly melted charges of crucible steel

	C.c. per 100 g.
Steel without blow-holes	132
Steel with blow-holes	67

With regard to the latter, the two charges were melted in separate pots at the same time, and it is admittedly difficult to determine similarity of condition during melting so far as gas content is concerned.

It may, however, be taken as proved that deoxidation does not necessarily mean the diminution of the total gas in solution.

Since deoxidized steel contains less FeO, the gas given off should have a higher CO_2:CO ratio than oxidized steel, and the results of Goerens again enable this to be confirmed. Taking samples from two electric-furnace charges after the removal of the phosphorus slag and again after deoxidation with ferrosilicon and ferromanganese, and extracting the gas, it was found

	CO_2:CO Ratio per Cent	
Before deoxidation	8.8	7.3
After deoxidation	60.0	21.3

In the first charge the manganese was 0.08 per cent and in the second 0.13 per cent at the time of taking the first sample, showing that the former was in a more highly oxidized state than the latter, and consequently it gives a greater difference after deoxidation. The theoretical deductions are strikingly confirmed.

As calculated in Appendix II, the composition of the gas in equilibrium with solid iron and FeO at the solidifying temperature, taken as 1,500 deg. C., is roughly CO_2 = 7.8 per cent, CO = 92.4 per cent, so that even if pure CO_2 were given off from the solidifying steel it would immediately be reduced again to CO by reaction with the solid iron until the composition of the gas approached this value. The fact that the gas liberated from an ingot burns with the blue flame of CO does not imply that it was given off as such during the solidification.

Estimation of Gases in Steel

In steel, from what has previously been said, the gas content in the solid state will be proportional to the gas content in the liquid solution, but the determination of the exact composition and quantity of this gas presents grave practical difficulties.

Two methods only so far have been used—the extraction of the gas by heating the sample in a vacuum (Baker, Boylston, Donaldson, etc.) and the fusing of the sample in a vacuum with tin and antimony, which have practically no dissolved gas themselves (Goerens). In the first method, any gas which is evolved which does not possess the composition necessary for equilibrium according to equation (7) for the temperature of the experiment will tend to react with the steel until it does possess that composition. Thus the composition found must have been modified in a quite indeterminate manner by reaction taking place at a lower temperature. The sum of the volumes of CO_2 and CO, however, gives the exact volume of the mixed gases at the temperature of solidification. The composition may not be the same.

With regard to the second method, the carbon contained in the steel is insoluble in the alloy and floats to the surface, where it remains, at the same time reducing the CO_2 in accordance with the reaction

$$CO_2 + C = 2CO \qquad (10)$$

This reaction not only varies with the temperature but also with the pressure of the gases, so that the results obtained only give the volume of the gas originally contained exactly, when expressed as CO_2 equivalent. That is, the volume of CO_2 plus ½(volume of CO) gives exactly the volume of mixed gases originally contained by the steel.

How far the composition is altered depends on the rate of evolution, so that the effect is merely to mask the differences in composition by an uncertain amount. Qualitative deductions can, however, still be drawn from the results, and it is the object of this paper to show how such deductions give an insight into the complex conditions existing in liquid steel during manufacture.

Appendix I

The heat of reaction at ordinary temperatures for the reaction

$$FeO + C = CO + Fe - 35.6 \text{ cal.}$$

is —35.6 cal., and the heat of reaction at the temperature of a melting-furnace, 1,600 deg. C., can be calculated in the following manner:

[10] *Jour. Iron and Steel Inst., C. S. M.*, 1910, p. 157.
[11] *Ferrum*, vol. 12, p. 78.
[12] *Jour. Iron and Steel Inst., C. S. M.*, 1902, p. 224.

From Nernst's theorem, using the accepted symbols

$$Q = Q_0 + \beta T^2$$
$$\frac{dQ}{dT} = 2\beta T = C_r - C_p.$$

There are no measurements of the molecular heat of ferrous oxide, since it has never been isolated pure, but Richards gives the value at 0 deg. C. of the specific heat of

Fe_2O_3 as 0.1456
Fe_3O_4 as 0.1447

so it can be assumed that the specific heat of FeO is in the neighborhood of 0.145, which gives a molecular heat of 10.45.

Mol. heat of carbon at 17 deg. C.	1.92
Mol. heat of CO at 17 deg. C.	6.71
Mol. heat of Fe at 17 deg. C.	6.15

(These values are calculated from Kaye and Laby, *Physical Constants.*) From these results,

$$C_r - C_p = 12.37 - 12.86 = -0.49 = 2\beta T,$$

and since the values were calculated at 290 abs.

$$\beta = -9.0 \times 10^{-4}$$

At $T = 290$ deg. abs., $Q = -35{,}600$, so that at $T = 1{,}873$, $Q = -38{,}700$. The difference is therefore negligible, and no appreciable error is introduced by taking the values at ordinary temperatures.

To find the difference in the value of the equilibrium constant K

$$\frac{d}{dt} \log K = -\frac{Q}{RT^2} \qquad (11)$$

and on integrating

$$\log \frac{K_1}{K_2} = -\frac{Q}{R}\left\{\frac{T_1 - T_2}{T_1 T_2}\right\}.$$

The ratio between the value of K at 1,600 deg. C. and K at 1,550 deg. C. is consequently

$$\log \frac{K_1}{K_2} = \frac{38{,}700 \times 50}{2 \times 2.30 \times 1{,}873 \times 1{,}823} = 0.124$$
$$\frac{K_1}{K_2} = 1.33.$$

Since $K = \dfrac{C_{CO}}{C_{FeO}\, C_C}$, an increase in K implies an increase in CO or a diminution in the product of the bottom terms. The steel is, however, saturated with CO, and, like all gases in solution, the saturation strength must diminish very considerably with a rise in temperature. At the finishing stage, pigging back is usually started when the carbon is in the neighborhood of 0.17 to 0.20, so that the carbon concentration is practically constant and independent of other conditions. An increase in the value of the equilibrium constant of 33 per cent, as found above, means a reduction in the amount of ferrous oxide in solution of more than 33 per cent.

Appendix II.

The reaction

$$FeO + CO = CO_2 + Fe_1 + 3.7 \text{ cal.}$$

can be treated in exactly the same manner as the previous reaction in Appendix I, but it presents some peculiar features. To begin with, the log K from Baur and Glässner's results plotted with 1/T does not give a straight line, which implies that Q varies with temperature to an appreciable extent.

The heat of reaction at ordinary temperatures is $+3{,}700$ cal. and the molecular heat of CO_2 is 8.9. This gives, as before

$$2\beta T = C_r - C_p = 17.16 - 15.05 = 2.11,$$
$$\therefore \beta = 3.6 \times 10^{-3}$$

This value is unusually high. At 825 deg. C. the heat of reaction Q_{825} is

$$Q_{825} = 3{,}400 + \beta(1{,}098)^2 = 7{,}750 \text{ cal.}$$

The equilibrium constant K has the following values:

750 deg. C.	1.56
900 deg. C.	2.51

which, calculating back by means of equation (8), Appendix I, gives

$$Q_{825} = 7{,}650 \text{ cal.}$$

This agrees very well with the previous value, found by quite a different method.

Substituting $Q_0 + \beta T^2$ in the integration of equation (11), Appendix I, the value of K at different temperatures will be:

1,200 deg. C.	5.8
1,300 deg. C.	7.5
1,400 deg. C.	9.5
1,500 deg. C.	12.1
1,600 deg. C.	15.2

The gas given off from a steel ingot immediately after solidification gave a ratio for K of 11.0,[13] and at lower temperatures 3.1 to 4.2. In the former case the temperature cannot have been far removed from the temperature of solidification, which was in the neighborhood of 1,475 deg., and in the latter case the temperatures were probably about 700 to 800 deg. C. These figures show the great importance of equilibrium conditions, and support the contentions of the author regarding the methods of estimating the gases in solution in steel.

[13] Baraduc-Muller, *loc. cit.*

Northwest Magnesite Co. Not a Monopoly

One of the principal arguments used against tariff on magnesite before the Ways and Means Committee was that the magnesite production of the United States is in the hands of the Northwest Magnesite Co. This concern was characterized as a monopoly. This charge is declared by Roy N. Bishop, general manager of the Northwest Magnesite Co., as being entirely unjustified. In the hearings on magnesite before the Senate Finance Committee Mr. Bishop said in that connection:

"Because we put $750,000 into a plant and developed magnesite so badly needed by the country during the war, we were charged in the previous hearings before the Ways and Means Committee with being a monopoly. A complete refutation of that is that we own only one-eighth of the raw material in the United States and that we never have produced more than 35 per cent of the magnesite that has been produced in the United States. As soon as a tariff is granted on it, those who own the other seven-eighths of the raw material will become very active competitors."

The cost of magnesite to the Northwest company, Mr. Bishop testified, is a little over $21 a ton. He declared that the company had sold at that price during the war, but "the people to whom we sold it in turn sold it to the steel companies with an addition of about $10 a ton to our price. For practically indorsing the bill of lading, they made a greater profit out of the magnesite than we did."

The Sterilization of Water by Means of Ultra-Violet Rays*

Records and Information on Potable Water Installation for Isolated Plant Supply—Fluctuations of Bacteria Counts in Raw Water — Exposure Required for Ray Sterilization — Water Consumption Rates and Quantities per Capita — Capacity of Ultra-Violet Ray Apparatus

By WALTER L. DECKER†

SCANNING the pages of history, we note that time after time this and that community has been visited by some dire epidemic which has caused the death of thousands and thousands of people. Failing to realize the cause, it was often attributed to the wrath of God. Having run its course and passed away, people settled down again to their former mode of existence.

With advancing knowledge and research, investigators began to doubt the wrath of God theory and began, by the process of elimination, the systematic study of cause and effect. Eventually it was found and proved that the water used by the community was the cause of the trouble. Chemical analysis failing to show the presence of any deleterious salts in the water that would cause sickness, resort was had to the microscope. This finally revealed the presence of certain organisms, invisible to the naked eye, which if eliminated from the water removed the cause of the trouble.

Suitable Drinking Water

Our former ideas of a suitable drinking water must be modified. Water may appear clear, cool and sparkling and yet contain organisms which are inimical to one's health.

A pure water may be defined as one which contains no disease-producing bacteria or an excess of organic matter of any kind. An impure water is generally defined as one which receives more or less sewage, one therefore that is not fit for human consumption. A pure water supply is one of the best safeguards of the health of a community. A relatively small number of diseases are transmitted by impure water. These diseases are typhoid fever, dysentery and Asiatic cholera. A pure water supply seems to affect the general health of a community and to decrease its death rate wholly apart from the decrease due to the elimination of the specific diseases mentioned. This is doubtless due to the fact that the impure water so affects the average health of a community that the individuals become more readily susceptible to other diseases.

The increased growth of our cities, with increased contamination of our water supplies, has brought about a general awakening of the community to the importance of the arts of sanitation. Bacteriology has ceased to be a subject of interest and importance to the medical profession only, but has become intimately connected with the work of the chemist, the biologist and the engineer. To the sanitary engineer the subject of bacteriology is indispensable.

Micro-Organic Life

Bacteria are the most numerous and the most widely distributed of living things. They are found in the surface of the earth, in the water under the earth, and in the air above the earth. Wherever there is life, waste matter is constantly being produced, and this finds its way to the earth or to some body of water. The excretions of animals, the dead tissues and broken down cells of both animals and plants, as well as the wastes of domestic and industrial life, all eventually find their way to the soil. In a majority of cases these substances are not of such chemical composition that they can be utilized at once by green plants as food, but it is first necessary that they go through a decomposition or transformation in which their chemical nature becomes changed, and it is as the agents of this transformation that bacteria assume their greatest importance in the world of life. When a bacterium cannot multiply, the only vital activity which can take place is a katabolic wasting away, which soon proves destructive, and the higher the temperature the more rapidly the fatal result is reached.

Bacteriology may be defined as that branch of science which treats of the forms, functions and activities of bacteria. The lines of demarcation between bacteria, yeasts, and molds of the vegetable kingdom, and certain protozoa of the animal kingdom are very poorly marked. It is not difficult to differentiate between the higher animals and plants, since there are many points of contrast plainly to be seen. With the microscopic organisms much greater difficulty is experienced, and some intermediate forms are known that constitute a complete series of intergradations between the two groups.

Types and Growth of Micro-Organisms

Four types of cells are found among bacteria: spherical, rod shaped, spiral and filamentous, these in turn being called coccus, bacillus, spirillum, and trichobacteria. All bacteria multiply in but one way, by a simple splitting of a cell into two. This may be termed vegetative reproduction. Some bacteria produce specialized resistant cells fitted to reproduce the species after a period unfavorable for growth. These are termed spores.

Chemicals may stimulate the growth of an organism, they may partially or completely inhibit its growth, or they may destroy it. Thus, a germicide is any substance which will kill micro-organisms, and an antiseptic is one which inhibits their growth without necessarily destroying them.

In general it may be stated that the plant cell differs from that of the animal by the possession of a firm and well differentiated wall, wholly distinct from the contained protoplasm. The typical cell wall of plants is made up of cellulose; the limiting membrane of the animal cell is nitrogenous.

Plenciz first clearly stated the germ theory of disease in 1762, claiming that each disease was caused by a particular kind of organism. This relationship was

*A paper read before the Cleveland Engineering Society, January, 1920.

†Construction Engineer, The American Shipbuilding Co.

later worked out more satisfactorily by Pasteur, Koch and Weigert.

Bacteria live upon organic matter, taking in oxygen and giving out carbonic acid. In the absence of dissolved oxygen gas in water they take their oxygen from the organic matter itself; that is, they decompose it, giving out not only carbonic acid, but also carbon monoxide, methane and other gases. This process has been sometimes called anaërobic respiration, that is, respiration without air. It is also called putrefaction.

Bacteria in Water and Their Quantitative Determination

Sedimentation is only one method by which bacteria are removed from water. We find that the bacteria furnish food for the protozoa; they in turn provide food for the rotifera and crustacea; they in turn are consumed by fish; and fish in turn provide food for men. Pathogenic germs when scattered through a mass of water cannot be detected by ordinary microscopical methods on account of their small size and because they

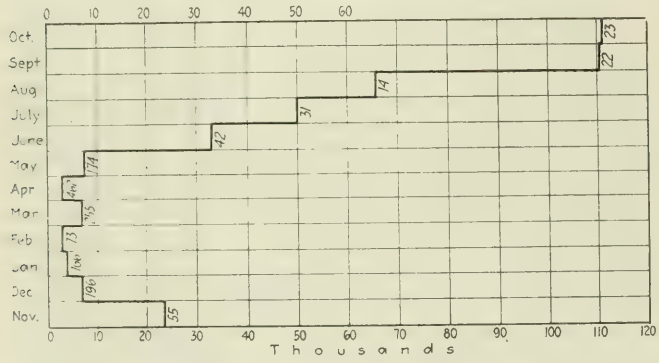


FIG. 1. MONTHLY FLUCTUATION OF BACTERIA IN RAW WATER AT WYANDOTTE

are greatly outnumbered by the ordinary water bacteria. Perhaps the most important service that the microscopical examination renders is that of explaining the cause of the taste and odor of water and its color. The microscopic organisms found in water show variations in their seasonal occurrence as great and almost as characteristic as those of land plants.

The *Bacillus coli* is a normal inhabitant of the intestinal tract of man and many other animals, and occurs regularly in their excreta, and on this account it is of the highest importance to sanitarians, since its presence in water supplies is a direct evidence of sewage pollution. Specific disease germs are difficult to isolate even when they are present, and water may be grossly polluted with sewage without any specific disease germs being present. All sewage pollution, however, is potentially dangerous, since where fecal matter exists, disease germs are at any time likely to be present.

A test for fecal matter as distinguished from infected material is therefore essential, and for such a test the colon group of bacilli are especially well suited. They are not dangerous in themselves, but they are significant indices of the probable presence of disease germs. What we dread in drinking water is the presence of pathogenic bacteria, mainly from the intestinal tract of man, and it is quite certain that the related nonpathogenic bacteria from the same source will behave more nearly as these disease germs do than will any chemical compound.

The procedure for the quantitative determination of bacteria in water consists in mixing a definite amount of a suitably collected specimen of the water with a sterile solidifiable culture medium and incubating it for a sufficiently long time to permit reproduction of the bacteria and the formation of visible colonies which may be counted. The typhoid bacillus and the colon bacillus stand at the opposite ends of a series of many different varieties of organisms which are intermediate in their properties, which produce a more or less characteristic growth on solid media.

Wyandotte (Mich.) Drinking Water Supply

It was during the height of the German drive in 1918, when all of us at home were diligently striving for increased production or increased means for production, that the question of an adequate supply of drinking water arose at the Wyandotte plant of the American Shipbuilding Co., Wyandotte, Mich.

At the time, the writer was engaged in supervising the construction of some fifty-odd buildings at the various plants of the company. Lack of time prevented him from giving the subject the amount of thought and study which it merited. It was a case where decision must be made at once and the results left to the hope of future accomplishment. Due to continual sickness in Wyandotte and to the fact that another thousand employees must be added to this plant at the earliest possible moment, it became necessary, more than ever, to give some thought toward the prevention of sickness among such a body of men if the work was not to be delayed by their enforced absence.

Due to its adverse location just below Detroit, and due to Detroit's rapidly increased growth and population, the increased amount of sewage that was dumped into the Detroit River rendered Wyandotte's problem of an adequate source of drinking water a more and more perplexing problem. Wyandotte was taking its source of water directly from the Detroit River and treating same with bleaching powder before distribution in its city mains. On account of excessive contamination and the lack of a filtration basin the amount of chlorine that had to be used was exceedingly high. The water as a rule smelled and tasted of chlorine, which made its use objectionable from more than one standpoint. Fig. 1, showing a comparison of the contamination of the Detroit River above and below Detroit, gives a clear idea of Wyandotte's problem. The curve shows the monthly fluctuation of the average number of bacteria in the raw water and the numbers on the curve show for comparison the average number of bacteria as found in the raw water supply of the city of Detroit.

Sterilization With Chlorine

Chlorine as a disinfectant was first used about the year 1800, and hypochlorite of lime (bleaching powder) as early as 1854 was used by the English Royal Commission for deodorizing the sewage of London. The first practical use of chlorine in water treatment in this country was in 1908, when Johnson used hypochlorite of lime in the treatment of the Bubbly Creek water at the Union Stock Yards in Chicago. After treatment and filtration, laboratory tests showed the effluent from the filters to be more nearly free from pathogenic bacteria than the water being furnished to the City of Chicago taken from Lake Michigan long distances from the shore. At present over 1,000 cities are treating their water supplies with either chlorine or hypochlorite of lime.

Laboratory experiments indicate that there is little

difference in the effectiveness of hypochlorite of lime and liquid chlorine as a sterilizing agent, but on account of losses in handling and mixing the bleach it requires a larger amount of chlorine in the bleach treatment than when liquid chlorine is used. In treating a water supply which is to be used largely for domestic purposes it must be considered that one of the primary qualities required in such a supply is an agreeable taste, and any treatment which cannot make water safe for drinking purposes without causing a disagreeable taste cannot be considered a successful and satisfactory method of treatment.

Since 1913, when the first commercial liquid chlorine machines were used, the popularity of this process has increased in a remarkable manner. Prior to this, water supplies were treated mainly with hypochlorite of lime. This process requires the use of mixing tanks for mixing the hypochlorite with water to a creamy consistency; storage tanks for holding the day's supply of chemical; and mixing tanks for regulating the amount of solution that is to be added to the raw water. The discharge of the hypochlorite solution is usually regulated either by maintaining a constant head on an orifice of variable dimension or by varying the head on an orifice of fixed dimension. Sludge is continually being formed in the storage tanks and the depth of same must be kept below the discharge outlet to prevent plugging of the pipe lines and measuring devices. For a small plant the bleach treatment is out of the question, as a trained chemist must be kept in attendance at all times in order to test the strength of each solution as it is made up.

The dosage or amount of chlorine to be added to raw water depends upon the following four points:

Content of readily oxidizable matter.

Temperature of water.

Method of application.

Contact period.

The amount of chlorine required for germicidal action is small and tests made by Race show that 1,000 *B. coli* per c.c. in absence of organic matter can be reduced to two *B. coli* per 100 c.c. (the U. S. Government standard) by 0.1 p.p.m. of available chlorine in 10 min. at 65 deg. The accompanying table shows the results of tests by Lederer and Bachmann upon the percentage reduction of various bacteria with a 15-min. contact period.

There is no marked difference in the resistance of ordinary water bacteria to chlorine, and the common intestinal organisms are also very susceptible to destruction by chlorine. The spore-forming bacteria usually found in water are derived largely from soil washings and from sewage and manure. The spores of these organisms are very resistant and survive all ordinary concentrations. In practice no attempt is made to destroy the spore-bearing organisms, as they have no sanitary significance and the concentration of chlorine required for their destruction would cause complaints as to tastes and odors if the excess of chlorine were not removed.

Action of Ultra-Violet Rays

What was desired at our Wyandotte plant was some system that would do away with this constant supervision, some system that would function day and night, whether the incoming water contained 100 bacteria or 100,000 per c.c. Upon inquiry, I found that there was such a system in existence, but that little reliance or faith was placed in it. To me the system appeared of value and I felt that the fault was mainly due to its practical application.

In order to have a better understanding of the system, we will revert back to the experiment that used to be performed in the physical laboratory. If a ray of sunlight, which appears white to the eye, is allowed to fall on a prism we have projected on the screen a succession of various colors called the spectrum. According to their refrangability the colors are arranged with violet the highest, then blue, green, yellow, orange and red as shown in Fig. 2.

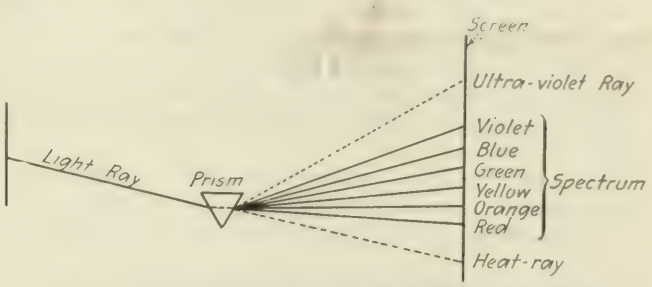

FIG. 2. DISSOCIATION OF SUNLIGHT INTO ITS PRIMARY COLORS

The vibrations of the ether are capable of producing other effects besides illumination. They constitute what is called radiant heat, and they are also capable of producing chemical effects, as in photography. Vibrations of high frequency are the most active chemically, those of low frequency have usually the most powerful heating effects. The color of lowest pitch is deep red, its frequency being about 400 million million vibrations per sec. The color of highest pitch is deep violet, its frequency being about 700 million million vibrations per sec. Fig. 3 shows a comparison of the frequency of vibration of the light waves with other invisible waves. Dividing the velocity of transmission (188,000 miles per sec.) by the various frequencies gives us the wave length of the various waves. Almost every source of light produces with the visible rays some wave lengths shorter than those which are perceptible to our eyes, these being called ultra-violet rays.

In so far as when intercepted they are converted into heat, all rays are heat rays, but neither the ultra-violet nor any other radiation is heat, but it may become heat when it ceases to be a radiation. Thus all radiations are chemical rays if they strike a body which is responsive to them. When a beam of radiation impinges upon a body it is resolved into three parts: one part is reflected, one part absorbed (converted into heat energy or chemical energy or some other frequency of radiation), and one part passes through and out of the body if it is not too thick. No body reflects, or absorbs, or transmits all the radiation, as even the most perfectly reflecting body absorbs and transmits some radiation.

The ultra-violet rays are extremely destructive to the eye; exposure even to a moderate intensity of them for a very few minutes produces a severe and painful inflammation, the after effects of which last for years, and long exposure would probably result in blindness.

Radiation impinging on the tissue of the human body or other living organisms exerts an influence depending on the intensity, power and frequency. The effect of radiation on the living protoplasm of the cells is stimulating if of moderate intensity, destructive if of excessive intensity. The intensity of light which is destructive to life largely depends on the amount of light to which the organism is accustomed. Those organisms that live in the dark may be killed by an amount of light which is necessary for the life of other organisms.

As men have lived for ages in the light, the cells of the human body are far more resisting to the light than the disease germs, which for ages have lived in the dark. Light, and more particularly the high frequency ultra-violet and the X-rays, thus have found a useful application in killing disease germs in the human body.

That the chemical activity of radiation is some form of resonance is made probable by the relation which exists between the active frequency and the weight of

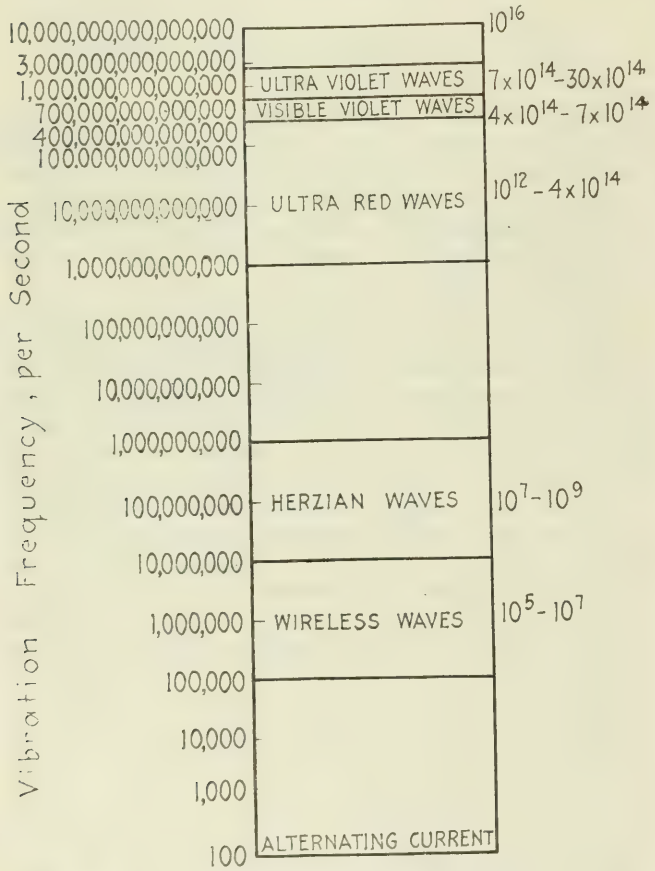

FIG. 3. COMPARISON OF VARIATION FREQUENCY OF DIFFERENT WAVES

the atom or molecule which responds to vibration. Thus, while the fairly heavy silver atom (atomic weight 108) responds to rays near the violet end of the spectrum, the much lighter oxygen atom (atomic weight 16) responds only to much higher frequencies. These very short radiations energetically produce ozone (O_3) by dissociating some of the oxygen molecules (O_2) into free atoms, and these free atoms then join existing molecules to form ozone.

Response to long waves of red and ultra-red light thus may be expected from atoms or groups of atoms which are very much heavier than the silver atom, and this indeed seems to be the case in the action of radiation on the life of plants. Those parts of the plants which contain chlorophyll, mainly the leaves, take carbon dioxide (CO_2) from the air through breathing openings, absorb the radiation and convert its energy into chem-

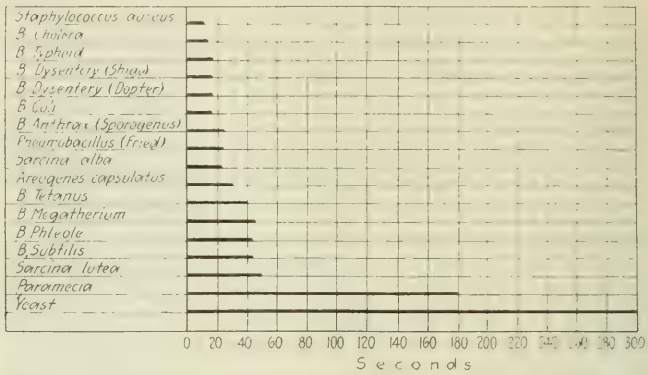

FIG. 4. SECONDS NECESSARY TO KILL DIFFERENT TYPES OF GERMS AT 200 MM. FROM A QUARTZ LAMP OPERATING AT 66 VOLTS, 3.5 AMPS.

ical energy, and use this energy in splitting up CO_2, exhausting the oxygen and using the carbon in producing the complex carbon compounds of their structure.

Sterilization With Ultra-Violet Rays

Ward was the first to demonstrate that the typical characteristic of ultra-violet light is the bactericidal power of these radiations. He threw the spectrum on an infected agar plate with the result that the parts of the plate which were exposed to the violet end of the spectrum did not show any growth of colonies, while the parts which were exposed to the red end of the spectrum developed growth.

The great source of ultra-violet radiations is the sun. Rivers and lakes are freed from a great part of their bacterial contents by the bactericidal power contained in the sun's rays. Small amounts of ultra-violet are produced by practically all artificial light sources. Electric discharges between metal electrodes are powerful producers of ultra-violet radiations. The disintegrated metal has to be replaced after being volatilized by the heat of the arc. The replacement is easiest if the disintegrated metal condenses easily and can be made to flow back, as is the case if mercury is chosen as electrode. The material in which the arc is enclosed has to be transparent to the discharge of ultra-violet rays. The only industrial material filling this demand is fused quartz. Glass which is transparent for visible light is nearly opaque

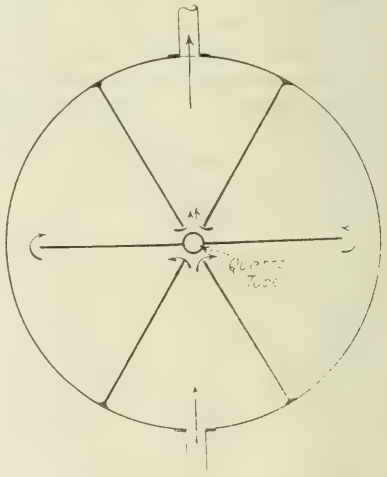

FIG. 5. ARRANGEMENT OF BAFFLES IN STIRRING APPARATUS

to ultra-violet light, hence cannot be used for this purpose.

The next step then was to determine whether ultra-violet rays would sterilize water. Accordingly various germs were placed in clear water and subjected to the action of these rays, and the length of time of exposure necessary to kill the various germs is shown in Fig. 4. Experiments have demonstrated that as the mercury vapor lamp can be run at different temperatures, by increasing or decreasing the voltage on the electrodes, its destructiveness of bacterial life is accordingly increased or decreased. An increase in watts, that is to say, of temperature, produced a much greater increase of the red and yellow than of the blue and violet, but it was found that the ultra-violet end of the spectrum increases about like the red end.

Water, if clear, is practically as transparent as air to ultra-violet rays. In many cases, however, it must first be filtered to free it from suspended matter and, if possible, also from colloidal matter, which would otherwise retard the passage of the rays. Careful observation of well-filtered water, however, nearly always reveals the presence of a small amount of suspended matter of a large enough size to allow microbes to be protected against the rays. To sterilize such water with safety it was found advantageous to agitate it while passing through the illuminated zone and to expose it several times to the light of the same lamp. This stirring up is best accomplished by a proper arrangement of baffles in the apparatus as shown in Fig. 5.

Having decided to try out this system of sterilization, the next point was to determine what system of records

FIG. 6. RECORD OF OPERATIONS AT WYANDOTTE

it would be advantageous to keep for the operating end. It was deemed advisable that a continuous record of performance would be an ideal one, for in this manner the operating department would have a clearer conception of what was taking place and the result of any changes that were made from time to time toward the betterment of the system. Accordingly, it was determined that it would be of interest to keep a continuous record of the following points: the bacteria in the raw water; the bacteria in the filtered water; the bacteria in the sterilized water; the turbidity of the raw and filtered water; the per cent of efficiency of bacterial removal in the filters alone; in the combined filters and apparatus; the grains of alum used per gal. of water in the filters; the rate of filtration in gal. per sq.ft. per min.; the hourly and daily consumption of water; the number of men working; the oxygen consumed in the raw water; the presence or absence of pathogenic germs in the treated water. A record of operations involving the above points is shown in Fig. 6. The system as at present installed consists of one 60-in. quartz filter, two 30-in. bone black filters, and two ultra-violet ray sterilizers in series, the normal capacity of which is 3,000 gal. of water per hr. free from pathogenic organisms.

The most important curve of the series is the second one from the top of the sheet reading, "Number of 10 c.c. tubes showing gas in 48 hr." It is this curve that denotes the presence or absence of pathogenic bacteria in the drinking water as same issues from the sterilizers. This curve is to be taken in conjunction with the curve marked, "Bacteria at 20 deg. C. in sterilized water."

You will note that with the excessive contamination with which we had to deal this latter curve denotes the presence of bacteria in numbers from 1 to 400.

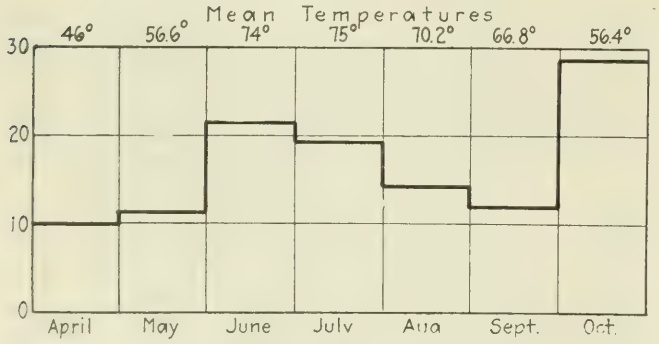

FIG. 7. GAL. OF WATER USED PER MAN PER 24 HR.

Remembering that the spore-forming bacteria are much harder to kill and that the objection to them *per se* is nil, as they are not inimical to one's health, the point then in question is to what family do the bacteria belong whose presence is shown in the curve of sterilized water.

Luckily, the pathogenic bacteria, together with the *B. coli*, are made to reveal their presence by a certain method of treatment. If placed in a tube of standard lactose solution they ferment same with the production of gas. Thus it is a simple matter to simply note the presence or absence of gas in the tube after 48-hr. incubation to determine with reasonable certainty the presence or absence of these objectionable bacteria.

In each case three tubes are planted for the filtered water and three tubes for the sterilized water. You will note that in the majority of analyses the water after passing through the filters showed the presence of *B. coli* in all three of the tubes. The curve for the sterilized water is a straight line zero curve, showing that the violet-ray sterilizer has functioned properly in killing all the *B. coli* germs that were left after passing the filters.

Rates of Consumption of Water

One of the interesting points developed was the excessive use of water per man. Being unable to find any record of the amount of water used per man in a distinct and separate system of drinking fountains, we had to simply fall back on an assumption of how much water might be used during the hottest days of summer and then multiply this by a factor of safety, or more properly speaking, a factor of waste. Fig. 7 shows the amount of water used per man per day for a period of seven months, from April to November. The water meter, being located next to the apparatus, naturally recorded the passage of all water, whether consumed or running to waste through some leak or leaks in the system of underground piping or in the drinking fountains. The sudden increase in the curve for October was unexpected and was due to a break in one of the underground mains, which continued to waste water until located. It was this loss of water that brought the average for the month higher than any other month, even though the number of men employed was considerably reduced.

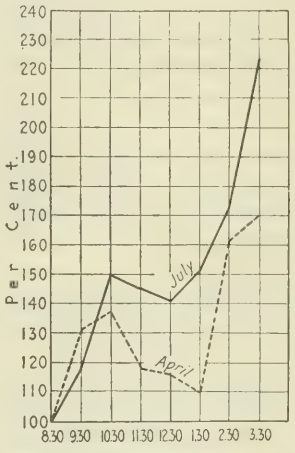

FIG. 8. PERCENTAGE OF WATER USED DURING THE VARIOUS HOURS OF THE DAY DURING THE MONTHS OF APRIL AND JULY

Fig. 8 shows a comparison of the amount of water used during the main working hours of the day. That used between 7:30 and 8:30 was arbitrarily assumed at 100 per cent and the amounts used during the other hours of the day as a percentage of this amount. The curve was first drawn up for July. It shows a very decided and pronounced increase from 1:30 to 3:30, which was quitting time. In order to ascertain if this same tendency for a drink during the last two hours of

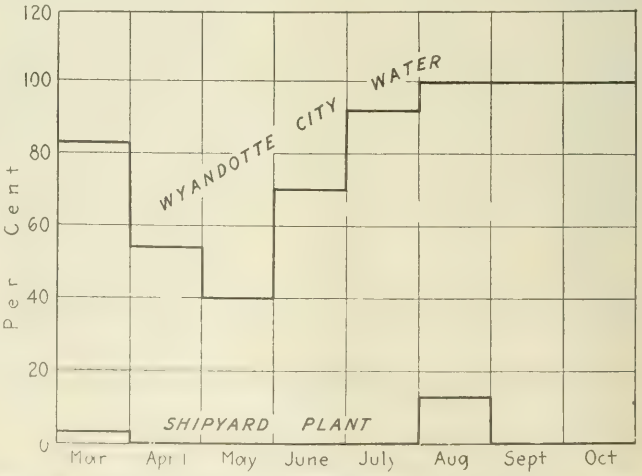

FIG. 9. PERCENTAGE OF TEST TUBES SHOWING PRESENCE OF PATHOGENIC BACTERIA

work existed during the cooler months, the month of April was picked out and the quantities for this curve were derived. From a study of the curves it would lead one to believe that the operator in the plant that recorded the readings had as good, or perhaps a better, survey of the amount of activity going on than the superintendent on the ground.

According to the old adage that "the proof of the pudding is in the eating," Fig. 9 is the proof that the system adopted provided a drinking water that was superior in all respects to that furnished by the city, and that our hoped-for results had been at least fairly well accomplished. Analyzing this record, with the inclusion of the November record, which was also zero, we find that during the nine months period on only three days was there any question as to the absence of pathogenic germs in the drinking water. On two days in August we fell down on our record for the reason that there was a sudden high increase in the bacterial count

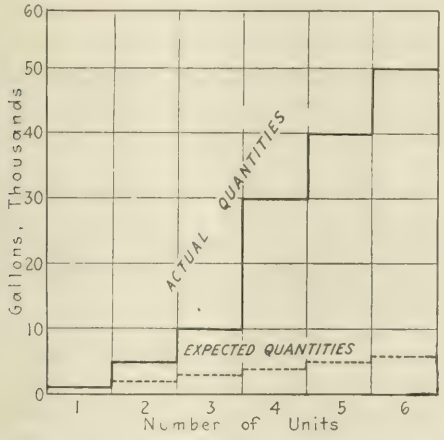

FIG. 10. GAL. OF WATER PER HR. PER UNIT OF VIOLET RAY APPARATUS

in the raw water, and at the same time the system was operating at 50 per cent overload, and one day in March when the capacity of the system was being increased and before all proper adjustments had been made.

An interesting development of the violet-ray apparatus is that the amount of water that can be treated does not vary in arithmetical progression with the number of units used. If the destruction of pathogenic germs depends upon the length of time of exposure to a light source, it would be only natural to assume that if one unit treated 1,000 gal. of water per hr. at a stated velocity through the apparatus should the velocity be increased by two, it would be necessary to put a second unit in series with the first so that the total length of time of exposure in the two would equal the one unit at half the velocity. Repeated tests, however, have demonstrated that such is not the case.

In the new units that are being developed it has been found that the amounts of water that can be treated by six units in series is as shown in Fig. 10. Beyond six units in series there is no further effect in the reduction of pathogenic organisms.

Recent tests have developed the unique and interesting fact that water treated with ultra-violet rays has a residual effect. If to a sample of water that has been sterilized fresh bacteria are added it was found that in an hour's time 90 per cent of these added bacteria had succumbed. What was in the water that killed them is at present open for study and research.

Belgian Industries One Year After the Armistice

THE Belgian Ministère de l'industrie, du Travail, et du Ravitaillement has just completed a survey of the status of unemployment and of the extent to which various Belgian industries had recovered in December, 1919. The investigation was conducted jointly by the Administration of Mines and the Labor Inspection Service, the former considering conditions in the extractive and metallurgical industries, and the remaining industries being covered by the labor inspectors, whose inquiry was extended to all establishments employing more than twenty workmen in 1914. Comparisons are made on the basis of production and employment on corresponding days in December, 1913, and December, 1919. It is obvious that comparisons made on the basis of one day's output may sometimes be misleading.

At first glance the results of the investigation are discouraging from the standpoint of comparative labor output. From the standpoint of actual production in comparison with pre-war output, they indicate, however, the remarkable industrial revival already commented upon by all recent visitors to Belgium. The effect of the general introduction of the 8-hr. day and of the large amount of work necessary to restore plants and mechanical equipment in some industries is shown by the following figures:

In December, 1919, the coal mines produced 94 per cent of the 1913 output, although labor employed amounted to 104 per cent of the pre-war figure. Coking plants were producing 37 per cent of the pre-war output while employing 53 per cent of their 1913 personnel. Plants for making briquets for the railways and other industrial uses attained 98 per cent of the pre-war production, with an increase of 9 per cent over the pre-war labor force.

The poor showing made by the iron and steel industry is no doubt attributable to the unusually severe damage suffered by such plants and the consequent necessity of employing large numbers in rebuilding and repairing foundries and mills and installing new machinery or stolen equipment recovered from Germany. With 60 per cent of the pre-war personnel, the iron foundries and steel mills produced in December only 34 per cent of their pre-war output, but this was a considerable increase over preceding months.

Still more serious is the condition of the zinc foundries, which in December were turning out 18 per cent of the pre-war production with 54 per cent of the labor employed in 1913. Special difficulties in obtaining ores and other raw materials are probably responsible for this large proportion of labor to output. The production of lead was only 9 per cent of the 1913 total, while copper production was about 28 per cent. In the quarries, an important and very diversified Belgian industry, production was slightly less than 50 per cent with a personnel of about 54 per cent.

According to the finding of the Administration of Mines, 115 establishments, including coal mines, coke and metallurgical plants, and quarries of various kinds, gave war destruction as the chief reason for subnormal production, eighty plants specifying lack of transportation facilities, fifty-two lack of adequate coal, forty-nine labor shortage, thirty reduction of working day, twenty-three lack of raw materials other than fuel, and thirty-three (all quarries) lack of orders.

Legal Notes

By Wellington Gustin

Pointers to Inventors and Users of Secret Processes

Some of the distinctions in the remedies one may have in courts of equity as against courts of law are given in a case from the Court of Chancery of Delaware involving the claims of an inventor who discovered a new process for making powder. (O'Neil vs. E. I. du Pont de Nemours & Co., 106 A., 50.) In his bill which states his cause of action the complainant alleges that in 1909 and 1910, while employed by the government of Brazil, he discovered an improved process for the manufacture of propellant explosives. This formula he submitted to one of the directors of a powder corporation for the purpose of selling it to that company. This corporation is alleged to have manufactured and sold great quantities of powder made in accordance with this process, without the knowledge or consent of the inventor. In October, 1915, the defendant corporation purchased all the assets and assumed the liabilities of this powder company, and in December, 1915, the inventor entered its employment.

The inventor further alleges that as soon as he learned of the use made of his process, he made inquiries and on Aug. 9, 1915, the defendant company presented to him applications for patents of his process, with assignments to be executed by him to it of the full and exclusive right to the process and invention. The assignments were made, as the inventor alleges, "with express understanding that your orator would be compensated for the value of the said process and invention, and relying upon the promises and inducements so held out to him, and relying further upon the bonus plan which had been promulgated by the said defendant company and the promises of reward therein contained."

Inventor Alleges Promises Were Fraudulent

Continuing, the inventor alleged that he was later informed by the company that the bonus plan did not apply to him. However, in July, 1918, he received notice that certain benefits under the bonus plan of the company had been granted to him, but these he refused to accept as not being fair or adequate compensation for the assignments. Then, it was alleged, by reason of undue advantage taken by the defendant company of the confidential relations between employer and employee, and of the distressful financial condition at the time the assignments were made, the assignments were secured by the defendant without consideration, and as the result of the fraudulent promises and practices of the defendant company, he had been deprived of the use of the process, and by its use the company made large profits to which he was entitled, and the defendant company was chargeable with the profits it made.

The relief asked for by the inventor were an injunction against the taking of any steps to obtain the patents on the process; for a reassignment of the applications for patents; and for an accounting by the defendant.

To these allegations of the complaint the defendant demurred, raising the question whether his remedy was in court of law or in equity, assuming of course, that the facts claimed gave the inventor a right to enforce compensation from his employer. If he has a full, adequate and complete remedy in a court of law then he has no right to relief in a court of equity, said the Chancellor. In either court he must prove the contract, or facts from which the law will imply a contract, and his damages or compensation for the use of his invention. At law he has power to examine the books of the defendant company as fully as in equity. Indefiniteness in the terms of the agreement, or his inability to prove the making of it, do not entitle him to equitable relief, said the Chancellor. The demand for payment would not create a right in equity, or at law. Neither would the tender of certain benefits as stated have any greater weight in equity than at law if used as evidence of a recognition of a duty to compensate the inventor. And the prayer for an accounting of the profits derived from the use of the process does not of itself give jurisdiction to equity.

Conclusion of the Court

The following are the holdings and conclusion arrived at by the court. Where an inventor disclosed his new process to his employer, relying on promises of compensation if it proved valuable, and the employer without his knowledge used it and made large profits, and also obtained for a nominal consideration an assignment from him of applications for patents, and thereafter tendered him compensation which he deemed insufficient, he has an adequate remedy at law for breach of contract, and therefore cannot maintain a suit in equity for an accounting.

Where an inventor for a nominal consideration assigned his applications for patents to his employer, which in addition agreed to compensate him if the invention proved valuable, but no price for such compensation was fixed, his action is in a court of law in a suit on a quantum meruit. Further, if the employer used the invention and derived a profit through such use, the employee inventor could not maintain a bill in equity for cancellation of the assignment of the application for patents; there being no fraud, actual or constructive, and his remedy being at law for recovery on the agreement to compensate.

Again, said the court, where an inventor disclosed his invention and assigned his application for patents thereon for a nominal consideration to his employer, which agreed to compensate him, failure so to compensate him would not in itself give a right to equitable relief, on the ground of the existence of a confidential relation between the parties. Further, where the employer, in addition to the nominal consideration, agreed to compensate the inventor if the process proved valuable, his employer's mere failure to compensate him under such agreement is not ground for recission of the agreement or cancellation of the assignments of the applications by the inventor, affording relief in a court of equity.

Regarding the inventor's right in his invention before issuance of patent, the Chancellor said he had a property right before the patent is obtained, which right is enforceable in a court, where he has agreed that another may use the invention in consideration that compensation be paid him in case the invention is found valuable.

Allegations of a bill in equity as to fraud must show the subject matter constituting the fraudulent conduct, as distinct from the evidence to prove the subject matter, said the Chancellor; and though a bill in equity characterizes defendant's acts by the expressions "fraud," "fraudulent," "fraudulent conduct and practices," where it avers no substantive facts as to fraud, no case of fraud is made out, so as to bring the case within equitable jurisdiction.

Aluminum Rolling-Mill Practice—IV Slabbing

Design of Rolling Mills and Plant Layout Are Discussed by the Authors, Together With a Detailed Account of All Hot and Cold Slabbing Operations Before Delivery of the Metal to the Finishing Department*

BY ROBERT J. ANDERSON AND MARSHALL B. ANDERSON

MILLS for rolling aluminum have been fairly well standardized as to design, and the essential features have not been changed in recent years. In the design of aluminum rolling mills, it is convenient to couple up a number of mills from one main drive so as to form a train. There is no advantage to be gained in driving the mills separately except in the case of strip mills.

ALUMINUM HOT MILL

An aluminum hot mill is a two-high mill employed mainly for breaking ingots down into slabs. Fig. 1 is a photograph of an aluminum hot mill, taken so as to show the front of the mill, while Fig. 2 is the same mill from the rear. The coupling stand for coupling up additional mills is shown in the foreground of both figures. In Fig. 1, a roughing mill is shown coupled into the system, at the left hand side of the photograph, thus forming part of a roll train. The hot mill illustrated in the photographs is a typical breakdown mill with geared mechanism on top of the mill for raising and lowering the upper roll.

Rolls are made of gray cast iron with a heavily chilled face, and their breakage is a heavy expense item in aluminum rolling. When the rolls become hot, the differential expansion of the gray and white iron, together with the internal strains usually present in a chilled roll, is often sufficient to cause fracture. Rolls fracture more often when the breakdown temperatures are too high or where there is lack of uniformity in the temperatures of successive ingots.

The hot mill shown in the photographs has rolls 28 x 84 in. (0.61 x 2.13 m.) running at the rate of 24 r.p.m. or a peripheral speed of 176 ft. per min. (53.6 m.). The flywheel in the system shown weighed 32 tons, and such a wheel is heavy enough to balance ten finishing mills, five hot mills, or a train of say one hot mill, two roughing mills and six finishing mills.

In the case of an aluminum hot mill, it is convenient to have a dial, shown on top of the mill in Fig. 2, divided into fifty equal parts, numbered consecutively. This dial is geared to the mechanism and motor for raising and lowering the upper roll in such a way that one revolution of the dial corresponds to a lateral movement in the upper roll of 1 in. Hence, fifty numbers equal 1 in., or one number equals 0.02 in. (0.5 mm.). By this arrangement the hot roller can figure his reductions readily. Due to wear in the journals and strain in the mill, the pointer of the dial may get out of alignment with the numbers and the position of the roll, and it is advisable to make adjustments at least daily. When a shift comes on, and before any rolling is performed, the screw boy should run the upper roll down tightly against the lower one; if the dial pointer is not at 50, i.e., zero, proper adjustment should be made.

Front and back floor plates (shown in Figs. 1 and 2) are important parts of breakdown mills, and unless these are of the correct design, much difficulty will be had in rolling. The front plate should be equipped with six small rollers set not more than 2 or 3 in. from the lower roll and if so placed the workmen will be relieved of much lifting. Back floor plates should consist of a heavy rod, set in the grooves from housing to housing; eight cast iron fingers, with small rollers on the end, are placed in a groove in the top of the rod. If a slab becomes stuck to the mill, the fingers will fly back and remove the strain from the back floor plate rod, as the slab goes around on the roll. Then the mill can be shut down and the slab removed. With rigid fingers, a slab stuck as mentioned will push on the fingers and break the back floor plate.

Roughing and finishing mills are similar in their general characteristics, and slabbing is done on a mill similar to a hot mill. Both roughing and finishing mills are of lighter construction than hot mills and slabbing mills because the work performed by the former is not so heavy. The upper roll is raised and lowered by hand, in the case of roughing and finishing mills, by means of a hand wrench on either side; the mechanism is shown in Fig. 1. Geared mechanism with motor drive is not used on these mills because the upper roll is not moved far, either up or down, as is the case with hot mills and slabbing mills. Roughing and finishing mills run at somewhat faster speeds than breakdown mills; for example, rolls in the former mills may run at the rate of 34 r.p.m., or a peripheral speed of 250 ft. (76.2 m.) per min. for 28-in. (0.71-m.) rolls. Roughing and finishing mills are built in various sizes

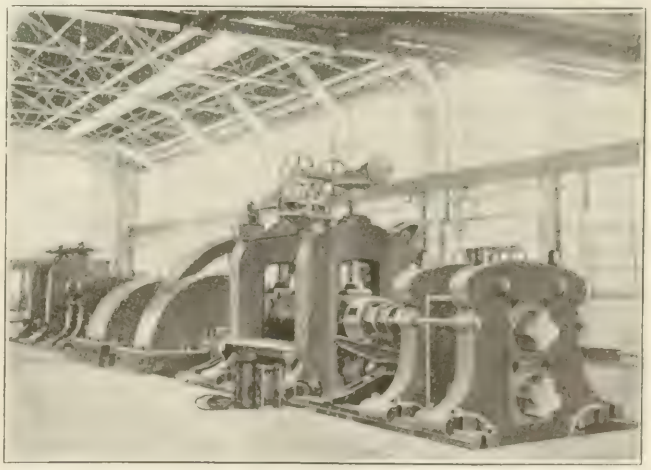

FIG. 1. ALUMINUM HOT MILL, 28-IN. ROLLS, IN TRAIN, FRONT VIEW

*For Parts I, II and III, see CHEM. & MET. ENG., vol. 22, Nos. 11, 12 and 13, March 17, 24 and 31, 1920, pp. 489, 545 and 599.

according to requirements; thus the rolls may be 28 x 60, 28 x 84, and up to 120 in. (0.71 x 3.05 m.).

Strip mills are usually operated as separate units, and this is so largely because of the amount of space required on both sides of a strip mill for handling coils. A typical single-unit strip mill has rolls 20 x 36 in. (0.51 x 0.91 m.), running at 25 r.p.m., or a peripheral speed of 131 ft. (40 m.) per min. Single-unit strip mills are driven by an individual motor, and they have mechanism similar to the hot-mill mechanism for raising and lowering the upper roll. This mechanism may be controlled by hand wheels rather than hand wrenches. A two-high continuous strip mill, with five mills in a row driven by one motor, is used for rolling strip faster than is possible in a single-unit strip mill. The reductions may be so arranged that the mills are set as follows:

Mill	Takes metal, in. thick (1 in. = 25.4 mm.)	Breaks to, in. thick (1 in. = 25.4 mm.)
First	0.375	0.300
Second	0.300	0.225
Third	0.225	0.150
Fourth	0.150	0.090
Fifth	0.090	0.064

A 0.375-in. slab will thus enter the first mill and emerge from the last as finished 14-gage strip, in one operation. The precise details in design of aluminum rolling mills vary with different builders, and the above brief descriptions give only the main points with regard to their construction. Furthermore, the layout for aluminum rolling mills will vary according to the amount of the output, the variety of the output, and other factors.

Layout of a Rolling Mill

In planning the layout of a mill, it is necessary to correlate carefully the capacities of the various mills with the melting and annealing equipment so that the complete mill will not be overbalanced in any department. No mention of the construction of mill buildings will be made other than to say that they should be well lighted, properly heated and ventilated and of modern design. Considering a mill of moderate size which shall have an output of 14,000 to 15,000 lb. (6.3 to 6.8 metric tons) of heavy sheet and 10,000 to 12,000 lb. (4.5 to 5.4 metric tons) of light sheet per day, the necessary equipment will comprise the following: Two 5,000-lb. (2,300-kg.) melting furnaces, one hot mill, two roughing mills, four finishing mills, and a strip mill. An ingot-heating furnace and two annealing furnaces will make up the metal-heating equipment.

Two 5,000-lb. melting furnaces can produce 9,000 lb. (4,100 kg.) of rolling ingots in 8 hr., or 27,000 lb. (12,250 kg.) per day. One five-track ingot-heating furnace will have sufficient capacity for preheating the ingots. A day shift can break down 27,000 lb. of ingots in the hot mill, and the same amount of metal can be cold slabbed on this mill by a night shift. Roughing, finishing and strip rolling performed continuously day and night with the equipment mentioned will turn out 24,000 to 27,000 lb. (11 to 12 metric tons) of finished aluminum sheet per day. In this case, we are assuming that about 33 per cent of the output consists of metal lighter than 20-gage and 66 per cent heavier, since heavy sheet can be rolled faster than light gage—for example, 14-gage cold-rolled aluminum sheet can be turned out about 1.5 times as fast as 20-gage, while the disproportion is larger with wider variations in gage.

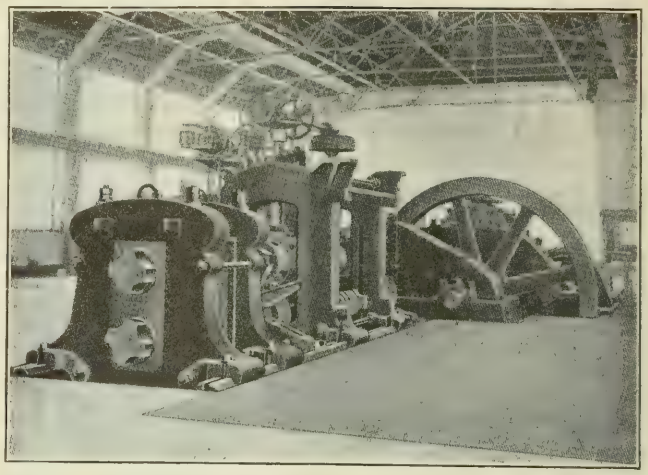

FIG. 2. ALUMINUM HOT MILL, 28-IN. ROLLS, IN TRAIN, REAR VIEW

With a mill as outlined, the hot mill, two roughing mills and four finishing mills would be run on one roll train with direct motor drive; the strip mill would be operated as a separate unit. In breaking ingots down into slabs, it is advisable to employ two hot mills in a plant of double capacity than the one outlined. With two hot mills, a crew of four men (one roller and three catchers) would be employed. After rolling metal on one mill for 30 min., that mill would be cooled, and the crew would move over to the other mill; the catchers would work on shifts, one catcher resting every 30 min. With one hot mill, ingots are being rolled only about half the working time because of the necessity for cooling the rolls at intervals.

A well-designed mill of the capacity mentioned should have at least five shears: A circle shear, a gang shear, a slab shear, and a large and a small shear for finishing and re-squaring. Slabs and light sheets should not be cut on the same shear. In addition to the equipment already mentioned, a mill of moderate size should include a flatter and a strip cleaner. The latter should be placed in a separate building if gasoline is used for cleaning. A suitable overhead electric crane, with say 5- and 20-ton hoists, should run the length of the main mill building.

Hot-Mill Crew

A hot-mill crew consists of the following men: An ingot pusher, a trucker, a roller, two catchers, and a screw boy. Strictly speaking, the ingot pusher should be classed as an ingot-furnace operative, and the trucker as partly an ingot-furnace and partly as a hot-mill operative. These distinctions are, however, somewhat academic in discussing rolling-mill practice from the metallurgical viewpoint, but they do become important in cost finding.

These operatives perform the following work: The ingot pusher stacks up cold ingots at the charging end of the ingot-heating furnace and operates the pushing ram so as to keep pace with the withdrawal of hot ingots from the front of the furnace. The trucker withdraws hot ingots from the front of the furnace by means of tongs, trucks ingots to the hot mill, and places them in position on the hot-mill floor plate for rolling. The roller is in charge of the work and puts the metal through the rolls from his side of the mill. The catchers, working on the opposite side of the mill from the roller, catch the rolled metal with tongs after each

pass, return it over the upper roll of the mill to the roller, and, after the final pass, place the resultant slab in a pile adjacent to the mill. The screw boy controls the reduction of the ingot with each pass by operating the electrically-driven upper roll through a hand controller.

Under good conditions, such a crew can roll, on an average, 275 4 x 12 x 14 in. (10 x 30 x 35 cm.) ingots in 10 hr. to 38 x 86 x 0.25 in. (96 x 218 x 0.6 cm.) slabs, the number being dependent upon the size of the ingots and the required slabs.

Rolling Temperatures

Allowing for the cooling of a hot ingot during the elapsed time between its withdrawal from the furnace and the first pass, the metal is rolled at a temperature of from 410 to 435 deg. C., although these figures are simply estimates. Some actual temperature measurements have been made by the writers in the case of ingots rolled directly from the molds. These measurements showed that the temperatures of succeeding ingots varied considerably, due to different pouring and mold temperatures and variations in time elapsed after pouring and before rolling. Furthermore, the interior of an ingot may be at a different temperature than the exterior; it may be higher than the exterior in ingots rolled directly from the molds, and lower in ingots preheated for too short a time, or cooled for too long a time after heating, prior to rolling. In any event, there is doubtless considerable variation in temperature not only between individual ingots but also in different parts of the same ingot. Fire-cracked slabs have been mentioned previously as being the result of too high breakdown temperatures. Fire cracks can be largely eliminated in the subsequent rolling if there is sufficient thickness after roughing so that the cracks can be eliminated on finishing.

Rolling Practice

Ordinarily, an aluminum ingot is rolled by giving it two or three passes so that the ingot is elongated to a length sufficient to make the desired width of the slab, whereupon this resultant thick slab is turned at right angles to the original direction of rolling and cross-rolled to the desired thickness. Provided an ingot of the correct size has been rolled, the resultant slab will be of the required dimensions. In breaking down, the first pass should be light so that the roller can obtain an idea of the condition of the metal; if too hot, the ingot will probably break or crack; if too cold, that fact will be noticed in the mill. If the required sheet is not too wide, say under 60 in. (1.5 m.), and 4 x 12 x 17 in. (10 x 30 x 43 cm.) ingots are being broken down, it is good practice to roll to the width with a heavy reduction on the second pass; on the other hand, if the required sheet is to be wider than 60 in., it is better to take only a fairly heavy second pass and roll to width on the third or fourth pass. In hot rolling ingots for wide sheets, it is better to make the passes reasonably light, otherwise the slab is likely to become distorted out of square and thus cause high scrap losses at the hot mill. Where the length is extremely disproportionate, it is difficult to keep the slabs even approximately square at the corners. Broadly speaking, the heaviest reduction should take place on the second pass, but the practice is necessarily variable.

Partial curling up or sticking of slabs to the hot-mill rolls is due to lack of kerosene, which should be liberally sprayed on the rolls before rolling each ingot. Kerosene is much better than so-called "solutions," made by mixing lubricating oils in water; it is often difficult to start an ingot when such solutions are used, and at times, after the ingot does start into the rolls, it will turn suddenly at right angles and roll on the wrong dimension. If an ingot curls up even though kerosene is used, it often helps if a little cup grease is rubbed on the surface; on the succeeding pass the slab will then straighten out.

Supposing now for explanatory purposes, 16-gage (1.29-mm.) cold rolled sheet is desired which shall, when finished, cut without an undue amount of scrap to 36 x 144 in. (0.91 x 3.66 m.). In order to obtain the required slab to make such a sheet, an ingot whose dimensions are 4 x 12 x 17 in. is first given a light pass in the hot mill—the 4 x 12 in. side entering the angle of nip on the rolls—and then a heavy pass (reducing about 1 in.) in the same direction and then a light pass so that the resultant thick slab after these three passes has approximate dimensions of 1.8 x 12 x 38 in. (4.6 x 30 x 97 cm.). The slab is then turned 90 deg. with the first direction of rolling and cross-rolled to ¼ in. (6.3 mm.) thick, when it will have approximate dimensions of 0.25 x 85.9 x 38 in. (0.63 x 218 x 97 cm.). The first three passes are calculated to produce a length of 38 in. (97 cm.), and when this thick slab is turned for cross rolling this 38-in. length becomes the width

Ingot is cross-rolled on the passes where the dial numbers are printed in bold face type (see text).
Many variations are possible in breaking down ingots.
1 in. = 2.54 cm. 1 dial division = 0.55 mm.

The exact reductions which are given to ingots may vary considerably for the reason that there are numerous combinations possible. An empirical scale for hot rolling is given in Table XV for breaking 3.5 x 12 x 24 in. (9 x 30 x 61 cm.) ingots to various widths and thicknesses, the length being allowed to run. The dial numbers refer to the numbers at which the pointer should stand after each set of the rolls, and those numbers in bold-face type indicate that the ingot should be turned at right angles (cross-rolled) on the pass. In each instance, the ingot is normally rolled by putting

the 3.5 x 24 in. side through the rolls on the first pass, so that cross-rolling may be interpreted as rolling at right angles to this dimension, i.e., on the 3.5 x 12-in. side. Where bold-face figures appear for the first pass, the 3.5 x 12 in. side enters the rolls; before each pass indicated by a bold-face number, the ingot will be turned.

After each ingot is broken down, the resultant slab is piled in a pile adjacent to the hot mill, and all lots are kept separate. After a track of ingots has been rolled, the rolls are cooled with a water spray from a perforated pipe for about 15 min. During this time the rolls are revolving. The water cooling should not be continued too long, as otherwise a coating may form on the rolls; this coating will then come off when the next ingot is rolled, and possibly scrap the slab.

Cold Slabbing

All aluminum slabs made on the hot mill, except those intended for strip rolling and sheets to finish 0.101 in. (10-gage, 2.59-mm.) or heavier, are slabbed cold on a slabbing mill. In a small plant, it is often necessary to slab cold on the hot mill at night, and run the hot mill on ingots only during the day. Whether that is done or a separate mill is employed does not alter the principles involved, since slabbing mills are the same as hot mills to all intents and purposes, so far as construction goes. Slabbing may also be done on a roughing mill.

On a slabbing mill there will be one roller, one helper, and two catchers. The roller and his helper work in front of the mill and the two catchers behind the mill. In slabbing, the roller and helper push the slab through the mill, and the two catchers receive it and pass it back over the top roll. In the manufacture of sheets, aluminum is handled with tongs only at the hot mill; during slabbing, roughing and finishing it is manipulated by hand.

The majority of hot-mill slabs are slabbed cold to one-half the original hot-roll thickness; for example, 0.25-in. slabs are reduced to 0.125 in., 0.30-in. slabs to 0.15 in., and so on. The exceptions to this rule have been stated previously in connection with the examples for calculations, and the slabbing thicknesses for sheets of various gages and sizes are given in Table IX.* The desired object is accomplished by giving the slab about five to fifteen passes with two or three sets of the rolls. Slabbing is a continuous operation, and there is no "spelling." Normal production will be about 2,000 lb. (910 kg.) of metal per hr. Kerosene should be swabbed on the rolls and metal during the slabbing operation in order to prevent the metal from sticking.

Slab Shearing

After cold slabbing, all slabs going to make sheet aluminum are sheared on both ends and cut to such lengths as will make (with certain exceptions to be noted later) the required finished sheets. Slabs are cut into from two to twenty-five pieces. Where only one large sheet is to be made from a slab, a hot-mill slab is sent directly to the finishing mill without cold slabbing, shearing or roughing. All slabs destined for the strip mill are sheared on both ends, and the edges are trimmed to remove any cracked metal; shearing the edges helps to prevent further cracking during strip rolling, and provides for straight edges. In the case of strip-roll slabs, two or four pieces are cut from the hot-mill slab.

Slab shearing follows cold slabbing in the mill scheme with the exceptions already described. The amount of scrap made by slab shearing averages from 10 to 12 per cent of the hot-mill production, but will vary with conditions. With correct shearing, it should be close to 10 per cent. Slab shearing is performed upon large power shears of well-known types, and the slabs should be sheared as fast as they are rolled on the slabbing mill. The slab shear is operated by a shearman and two helpers. After shearing, the slabs are stacked near the roughing mill, if they are to be roughed; some slabs are sheared and sent directly to the finishing mill; in either case, the sheared slabs should be piled near the proper mills.

In the example for calculating sheets, it was pointed out that very large shearing losses may arise in the manufacture of aluminum sheets because of miscalculations with regard to the size of ingots rolled. If the right size ingots are rolled, the slab-shear scrap should not exceed 10.1 per cent of the hot-mill output. There is 10 per cent allowed for rounded ends and other irregularities in shape, and 0.10 per cent is added because most of the calculations cannot come out exactly. An example is given in the following: In calculating an order for 16-gage sheets, 40 x 144 in., the figures are:

0.150 ÷ 0.050 = 3
160 ÷ 3 = 53+
106 ÷ 53 = 2, the number of cuts to a slab. This results in practically exact figures. Comparing this with an order for 20-gage sheets, 25 x 60 inches, the figures are:
0.125 ÷ 0.031 = 4
80 ÷ 4 = 20
177 ÷ 20 = 8 + 17, or there will be eight cuts to a slab and 17 in. of scrap.

The 17-in. scrap end is weighed with the slab-shear scrap, and 0.10 per cent allowed as an average will provide for such cuts. Excessive slab-shear scrap is due to wrong calculating, to wrong shearing by the shearman, and to poor breakdown practice at the hot mill.

(Part V, the last of the series on Aluminum Rolling-Mill Practice, dealing with finishing operations, will be published in our next issue.)

Imports and Exports of Chemicals

Imports and exports of certain chemicals, as reported by the Bureau of Foreign and Domestic Commerce, for January, 1920, and the figures for January, 1919, as finally revised, are as follows:

EXPORTS OF CHEMICALS

	Jan., 1919 Lb.	Jan., 1920 Lb.
Acids:		
Carbolic	229,497	440,832
Nitric	49,411	13,270
Picric	22	5,567
Sulphuric	1,067,763	1,768,749
Calcium acetate	55,765	3,632,782
Calcium carbide	2,286,388	736,959
Calcium chloride	1,579,847	2,983,782
Copper sulphate	2,847,199	346,947
Potassium chlorate	410,979	409,154
Soda:		
Caustic	17,402,125	14,180,004
Sal soda	1,453,780	552,193
Soda ash	15,034,056	5,676,972
Sodium silicate	2,008,597	1,771,143
	Value	Value
Dyes and dyestuffs	$2,318,061	$1,449,153

IMPORTS OF CHEMICALS

	Jan., 1919 Lb.	Jan., 1920 Lb.
Calcium acetate and chloride (crude), carbide and nitrate	11,260,828	5,684,135
Dyes	216,952	539,144
Gums	4,694,962	12,328,990
Potassium carbonate, including crude or black salts	120,953	1,289,938

Methods for Analytical Control of Electrolytic Zinc Production

A Description of the Methods Used at the Electrolytic Zinc Plant Laboratory of the Judge Mining & Smelting Co., Park City, Utah, for the Analysis of Leach and Electrolyte Solutions, Concentrates, Calcines and Leach Residues, Zinc Dust Precipitate and Anode Scale From Cells

By H. F. BRADLEY

IT IS not the purpose of this paper to describe analytical methods for all elements likely to be determined in electrolytic zinc work, but to present a few methods which have been tested and found especially suited to the materials produced in the process outlined below. These methods are in use at the electrolytic zinc plant laboratory of the Judge Mining & Smelting Co. No special originality is claimed, except possibly in suitably combining and modifying standard procedures.

The materials to which the methods apply are produced in the following process:

Concentrates consisting chiefly of zinc blende and pyrite are roasted to convert the zinc to forms soluble in sulphuric acid. The calcine is agitated with a slight excess of dilute H_2SO_4, and the excess acid neutralized with $CaCO_3$ or $Ca(OH)_2$. After settling and filtering, the solution is purified by agitation with zinc dust. The resulting pure electrolyte is electrolyzed with lead anodes and aluminum cathodes, the "cell tail" solution being used again as leach liquor.

Analysis of Leach and Electrolyte Solutions

Leach Solution

The solution used has been neutralized with lime but not purified by agitation with zinc dust.

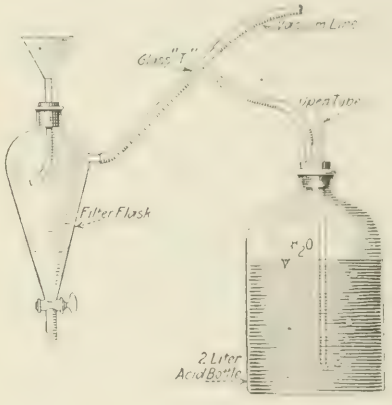
Copper. With pipette take 25 c.c. of solution, add 5 c.c. 50 per cent acetic acid, a little sodium or ammonium phosphate solution to precipitate any iron present, then 10 c.c. of 25 per cent solution of NaI. Titrate as usual with "hypo" (1 c.c. = 0.0025 g. Cu).

This method gives results very slightly higher than the precipitation as sulphide and subsequent titration with "hypo." In this solution, the As and Sb are in the higher oxidized condition, and do not interfere.

Cadmium. Measure a convenient amount of solution (depending on the cadmium content), say 100 to 200 c.c., add 15 c.c. H_2SO_4 for each 100 c.c. taken; then add slowly, with stirring, enough Na_2S (10 per cent solution of crystals) to precipitate the copper. Boil about 2 min., test with a drop of Na_2S, and if the copper is completely precipitated, filter hot, washing with hot water. Any CdS precipitated by the Na_2S dissolves again on boiling with the above strength of H_2SO_4 (27 per cent).

Cool the filtrate, and add 15 c.c. strong NH_4OH for each 15 c.c. H_2SO_4 originally added, stirring the solution during the addition. Cool again, dilute to twice the original volume of solution taken, and pass in H_2S 30 min. or more. The dilution and treatment with NH_4OH has reduced the acid strength to about 9 per cent, which is suitable for the precipitation of CdS. (It is usually necessary to start the precipitation by adding a few drops of NH_4OH after passing the gas 5 minutes).

Let the precipitate settle 20 min., and filter by suction on fine papers (such as Munktell's Swedish No. 0), used double with filter cone. A Shaw filter flask,* pear-shaped, with stopcock at the bottom, will be found convenient for suction filtering. A simple vacuum regulator, to prevent breaking the paper, is shown in the accompanying figure. Wash the CdS once with water, then dissolve it in a small volume of hot 1:1 HCl, opening the inner fold of the paper to expose all the precipitate, and finally washing four times with hot water. To the solution add methyl orange, then carefully add NH_4OH until the neutral point is just passed, then add 10 c.c. trichloracetic acid solution (40 per cent). Cool, dilute to 100 c.c., and repeat the H_2S precipitation, filtering and washing five times with Na_2SO_4 solution (about 15 per cent of anhydrous salt). If washed with water, CdS is likely to run through the filter after two or three washings.



Tear the filter into several pieces and place in the original beaker, which now contains 60 to 80 c.c. of cold 1:1 HCl. Add starch and titrate immediately with iodine (2.35 g. per liter) to a distinct blue color, which remains at least 30 sec. while the solution is stirred. The sulphur formed in the reaction causes a pale blue color which must not be confused with the true end-point. Whether or not the true end-point has been reached can be determined by adding more iodine and noting whether the color becomes permanently deeper. 1 c.c. iodine = 0.0010 g. Cd. Standardize the iodine against standard "hypo" (Cu × 0.884 = Cd).

If preferred, an excess of iodine can be added, the solution stirred for 2 or 3 min., then titrated back with "hypo" (see references 1 and 2). This method checks very closely with the gravimetric method in which the CdS is changed to and weighed as $CdSO_4$.

Solutions containing less than 0.05 g. cadmium per liter should be analyzed by the method given under "Pure Electrolyte." When very low concentrations of cadmium are precipitated with H_2S in acid solution, the results are usually too low by a considerable amount.

* Sold by Eimer & Amend, New York, N. Y.

Antimony. (References 3 and 4.) To 250 or 500 c.c. of solution add 10 per cent by weight of H_2SO_4, heat to boiling, and pass in H_2S about 60 min. Let the precipitate settle a few minutes, and filter on a Büchner funnel, washing five or six times with warm 5 per cent H_2SO_4 to which a little Na_2S has been added, then once with water. Boil the paper and sulphides with 50 c.c. of Na_2S (5 per cent solution of crystals), filter and wash with small volumes of hot water. Treat the filtrate for Sb exactly as in "Pure Electrolyte," below, from the point where $NaClO_3$ is added, etc.

Total Iron. Rapid method. (Reference 5.) To about 300 c.c. of neutral filtered solution add *two drops only* of H_2SO_4, then add $KMnO_4$ from a burette to a *faint* pink color. With pipette take 5 c.c. of this oxidized solution and place in a vial or colorimetric tube of clear glass. Add 2 c.c. of conc. salicylic acid (2 g. per liter), dilute to 25 c.c., mix and compare with standards. If the color is too strong for a comparison, dilute the oxidized solution to two, three or five volumes and repeat the color test, taking the dilution into account when calculating the Fe.

For Acid Solution. Take 20 c.c. of solution and titrate the acid with Na_2CO_3 and methyl orange indicator. Now titrate another 20 c.c. *without* indicator, stopping the titration a little short of the previous reading, so that the solution contains about 0.5 g. H_2SO_4 per liter. Dilute to 40, 60 or 100 c.c. and treat with $KMnO_4$ and salicylic acid as above.

Preparation of Color Standards for Iron. Dissolve 0.249 g. $FeSO_4$ crystals (purified by alcohol) in distilled water, add six drops of H_2SO_4, add $KMnO_4$ from a burette to a faint pink end-point, and dilute to 1,000 c.c. This solution contains 0.050 g. Fe per liter, and can be used straight or diluted to make standards of different values, measured amounts being treated with salicylic acid as above. Standards must be freshly prepared every three or four weeks.

For the determination of Zn, Mn, CaO and MgO, see "Pure Electrolyte," below.

Pure Electrolyte

Traces of impurities remaining in the electrolyte after agitation with zinc dust to displace ions electronegative to Zn are determined as follows:

Antimony and Copper. (Distilled water and pure reagents must be used throughout.) With a graduate measure 1,000 c.c. of solution, add 6 or 7 per cent by weight of H_2SO_4, then add slowly, with stirring, 30 to 50 c.c. of Na_2S (3 per cent solution of crystals; this must be free from chlorides if copper is to be determined). Heat to boiling and boil 1 or 2 min. Let the precipitate settle about 30 min., add a little more Na_2S, and filter by suction on Büchner funnel (10 cm.). (Whatman No. 30 papers, used double, are the best for this purpose.)

Wash four times with dilute H_2SO_4 to which a little Na_2S has been added, and once with water. Continue the vacuum about 1 min. after washing. Fold the paper as usual and place in ordinary funnel, opening the inner fold to expose all of the precipitate; wipe out sulphides adhering to the Büchner funnel and add to the main precipitate.

Now wash the paper with 30 c.c. of hot 3 per cent Na_2S, passing first part of filtrate through again (Whatman No. 30 papers filter rapidly at this point). Wash twice with small volumes of hot water.

To the filtrate add about 0.7 g. $NaClO_3$, heat nearly to boiling, add 15 to 20 c.c. of strong HCl, and boil off most of the chlorine. Cool 1 or 2 min., add 3 c.c. of freshly made 10 per cent Na_2SO_3, and boil a few minutes. (A sheet of asbestos paper under the beaker will prevent bumping.) Cool again about 2 min. and repeat the above treatment with Na_2SO_3 twice more to insure complete reduction of Sb. Add about 0.3 g. tartaric acid and boil down to about 25 c.c. to remove SO_2 and As.

Cool, add a piece of litmus paper, carefully neutralized with NH_4OH, make slightly acid with HCl, and cool again. Add starch, dilute to 100 c.c., add an excess of $HNaCO_3$ or HNH_4CO_3, and titrate immediately to a distinct blue end-point, using the same iodine as in titrating Cd. (See "Leach Solution," above.) The end-point is much sharper in the presence of tartrates than in their absence. One c.c. iodine = about 0.0011 g. Sb (Cu $\times$ 0.945 = Sb).

A synthetic solution resembling our electrolyte was made up from spelter, c.p. H_2SO_4, $CaCO_3$, distilled water and other materials known to be practically free from Sb. Various amounts of Sb (as tartar emetic) were added to 1,000 c.c. portions of this solution and the assays carried through exactly as above, with the following results:

Sb Added, Grams	Sb Found, Grams	Sb Added, Grams	Sb Found, Grams
None	0.0003	0.0020	0.0020
None	0.0004	0.0030	0.0029
0.0010	0.0012	0.0040	0.0040
0.0010	0.0011		

The "blank" appears to be practically compensated by some other factor, probably the small amount of Sb_2S_3 remaining in solution.

Copper. After washing with Na_2S, the filter paper still contains the CuS. Pour upon it a few drops of neutral zinc nitrate solution (made by adding a slight excess of ZnO to 1:3 HNO_3; both this solution and the Na_2S used above must be free from chlorides). Place the paper on a scorifier and burn in a muffle at a red heat. The zinc nitrate changes to ZnO and effects the complete oxidation of the CuS to CuO, etc.; any chlorides present will cause loss of $CuCl_2$ by volatilization.

Dissolve the ZnO and CuO in not more than 1 c.c. of 1:2 HCl (warming for a few seconds may be necessary). Add 5 per cent KOH until a permanent white precipitate forms; dissolve the precipitate with an excess of acetic acid, keeping the volume as small as possible; add a few drops of sodium or ammonium phosphate solution to precipitate traces of iron, then about 1.5 g. solid NaI and a little starch. Titrate with weak "hypo" (5 or 10 g. crystals per liter).

The above treatment with zinc nitrate, etc., making unnecessary the usual evaporation with HNO_3, can be applied to as much as 0.020 g. of Cu, possibly more, if the CuS has been precipitated in a fine granular condition. The use of phosphate for Fe was noted in *Chem. News,* vol. 118, pp. 193-4 (R. H. Deakin).

Cadmium. (Use distilled water throughout). To 500 c.c. of solution add 50 g. NH_4Cl, heat to about 60 deg. C., add NH_4OH gradually until zinc hydrate dissolves, then about 15 c.c. excess. Dilute to about 800 c.c., and add slowly, with stirring, 20 c.c. of Na_2S (1 per cent solution of crystals). Heat to boiling and boil about 30 sec.

Let the precipitate settle about 40 min. and filter on a Büchner funnel, using fine double papers (Munktell's Swedish No. 0). Wash several times with warm 1:6 NH_4OH, to remove soluble zinc. Continue the vacuum 1 min. after washing.

Tear the paper into several pieces and place in a 250 c.c. beaker, wiping out any sulphides adhering to the

Büchner funnel. Add 30 c.c. 25 per cent H_2SO_4, boil 2 or 3 min. and filter hot, by suction, washing four times with water.

The filtrate contains Cd and some Zn. Add methyl orange, just neutralize with NH_4OH, add 10 c.c. trichloracetic acid (40 per cent), and determine Cd by two precipitations with H_2S and titration exactly as in "Leach Solution," above. The above method was derived from a method of spelter analysis formerly used by the Anaconda Copper Mining Co.

Zinc. For fairly accurate work, measure 5 c.c. of solution with pipette, add a few g. NH_4Cl, 0.5 to 1 g. ammonium persulphate, dilute to 100 c.c., add 15 c.c. NH_4OH, and boil 6 to 8 min. Filter off Mn and Fe hydrates, washing with dilute NH_4OH. To the filtrate add $CuSO_4$ solution to give a distinct blue color, acidify with 6 to 8 c.c. excess HCl, and add 5 c.c. of Na_2S (20 per cent solution of crystals) to precipitate Cu. Heat not above 75-80 deg. C., and titrate as usual with ferrocyanide.

The $CuSO_4$ acts as a better indicator than methyl orange, and the presence of CuS appears to give a less deceptive end-point than when Cu is absent. But the end-point will often be very deceptive if the solution has been heated to boiling before titrating.

For very accurate work, some standard gravimetric method is preferable.

Manganese. Pipette 20 c.c. of solution into a 100 c.c. measuring flask (calibrated against the pipette), dilute to the mark with distilled water, transfer the beaker, and mix well. If the Mn in the original solution is 0.4 g. per liter or less, take an aliquot of 20 c.c.; if more than 0.4, take 10 c.c., etc. Place the aliquot in a 150 c.c. beaker containing 0.020-0.023 g. $AgNO_3$ and 4 or 5 c.c. HNO_3.

Dilute to 30 c.c., cover, and heat to incipient boiling. Add about 1 g. ammonium persulphate and heat gently (just below boiling) for 1 min. after the pink color appears. Cool to room temperature, dilute to 100 c.c., and add 3 c.c. of NaCl (5 g. per liter). Titrate with sodium arsenic until the pink color just disappears and only the white of the AgCl is visible.

Sodium Arsenite Solution. Dissolve 0.675 g. As_2O_3 in hot distilled water containing 2 g. Na_2CO_3, and dilute to 1,000 c.c. (1 c.c. = 0.0002 g. Mn). Theoretically, about 0.908 g. of As_2O_3 is required, but the reaction actually does not proceed according to the usual equation. Apparently, this is not realized by some writers giving this method.

Standardize the arsenite as follows: From a burette run 10 c.c. $KMnO_4$ (0.574 g. per liter) into a small beaker containing the $AgNO_3$ and *colorless* HNO_3. Dilute to 100 c.c., add the NaCl and titrate as above. Run at least three standards and take the mean. If 1 c.c. $KMnO_4$ = 0.0010 g. Fe, 10 c.c. contains 0.001967 g. Mn.

Traces of chlorides do not interfere, but any considerable amount should be avoided. If a large number of determinations are made daily, time can be saved by using "Analoid Tablets" (see reference 8).

Total Iron. This is usually less than 0.002 g. per liter. To about 200 c.c. of neutral solution add *two drops only* of H_2SO_4. Add weak $KMnO_4$ from a burette to a faint pink end-point. Treat 25 c.c. with salicylic acid and compare with standard. (See "Total Iron in Leach Solution," above.)

Any considerable amount of strong acid destroys the color. Acetic acid may be present, but large amounts of Na or Zn acetate weaken or modify the color so as to render the test useless.

Arsenic. This is seldom determined at our plant, being present only in traces in the pure electrolyte. We should say that the Gutzeit method might be applied here. (Reference 6.)

CaO and MgO. Pipette 20 or 40 c.c. of solution, add 20 to 30 g. NH_4Cl and 3 g. ammonium persulphate. Dilute to 75 c.c., add 15 c.c. NH_4OH, boil 8 min., and filter by suction on fine papers, to remove Mn. Wash with dilute NH_4OH.

To the filtrate add 1 g. oxalic acid, or ammonium oxalate, boil, filter, and wash once with NH_4Cl solution. Dissolve the precipitate in hot 1:3 HCl, add a little NH_4Cl and oxalic acid, dilute to about 60 c.c., make alkaline with NH_4OH, boil and filter. Wash well with hot water and determine CaO as usual.

Combine the two filtrates from the calcium oxalate and determine MgO by the usual phosphate method, making a double precipitation.

"Cell Tail" Solution

H_2SO_4. Pipette 10 c.c. of solution into a beaker. If the solution contains suspended MnO_2 or the pink color of $HMnO_4$, add a very small pinch of ferrous sulphate and agitate until colorless. Dilute to 100 c.c. with distilled water, add methyl orange, and titrate with Na_2CO_3 (22 g. per liter) until the pink color has just disappeared and the solution is pure straw yellow. (1 c.c. = 0.020 g. H_2SO_4.

Add the Na_2CO_3 drop by drop when approaching the end-point; otherwise, the end-point will be passed before the indicator changes color, on account of the precipitation of zinc carbonate.

Unless H_2O_2 is available that is free from acid it should not be used to destroy the $HMnO_4$. This destruction of the $HMnO_4$ uses up some of the acid in the solution, but not enough to affect the results to any appreciable extent. $HMnO_4$ often destroys the indicator color or produces a false end-point which occurs too soon.

Determinations of other elements are made as given above.

Ores and Residues

Concentrates, Calcines and Leach Residues

Total Soluble Zinc (acid soluble + water soluble). The following method is due to C. A. Hansen of the General Electric Co., and gives the percentage of the total zinc solubles in 6 per cent H_2SO_4 under ordinary leaching conditions:

To 0.5, 1.0, or 2.0 g. of ore add 100 c.c. of hot dilute H_2SO_4 (7.5 g. per liter). Boil 5 min., cool 1 or 2 min., add a little NH_4Cl, 5 c.c. H_2O_2 (or ammonium persulphate if much Mn is present), then add 10 c.c. NH_4OH. Boil, filter and determine zinc as usual in the filtrate.

Actual tests have shown that the above result agrees closely with the zinc actually dissolved from calcines under leaching conditions at our plant.

Water-Soluble Zinc. Leach the sample with hot water, filter, precipitate Mn by boiling with NH_4OH and ammonium persulphate, filter and determine zinc as usual. The addition of $CuSO_4$, as in the case of zinc in "Pure Electrolyte," is helpful in determining the end-point.

Uranium nitrate usually gives a more satisfactory end-point than the acetate.

Cadmium. Dissolve 4 g. finely ground ore in HCl and HNO_3, add 15 c.c. H_2SO_4, and boil to fumes of SO_3. Cool, dilute to 100 c.c., boil, and filter, washing with small volumes of water.

To the filtrate add, with stirring, 4 or 5 c.c. 10 per cent Na_2S, heat nearly to boiling and pass in H_2S until Cu is completely precipitated (about 30 min.). Heat to boiling and filter hot, washing with hot water. CdS remains in solution in the above strength H_2SO_4 when the solution is hot.

Cool the filtrate, add 15 c.c. NH_4OH, cool, dilute to 200 c.c., and determine Cd exactly as in "Leach Solution," from the point where the Cu has been removed and NH_4OH added.

Manganese. Dissolve 1 g. ore in HCl and HNO_3, add 10 c.c. H_2SO_4, and boil to fumes. Cool, dilute to about 75 c.c. with distilled water, and heat to boiling. Cool, dilute to 100 c.c. in measuring flask, mix well, take a 20 c.c. aliquot and determine Mn as in "Pure Electrolyte."

Sulphur Present as Sulphate. Take a factor weight of ore, or any convenient fraction of the factor weight, add about 4 g. of c.p. $HNaCO_3$, then add 60 c.c. of boiling distilled water and boil gently 30 min. This converts practically all sulphates except $BaSO_4$ to the soluble form. Filter hot, washing with hot water. Carefully acidify the filtrate with 4 or 5 c.c. excess HCl, dilute to 250 c.c. and determine sulphur by the usual $BaSO_4$ method. (See reference 7.)

Zinc Dust Precipitate

Copper, Cadmium and Zinc. This material consists chiefly of these metals and their oxides, with small amounts of Pb and SiO_2.

To 1 g. of the precipitate add a little water, 5 c.c. HCl and 5 c.c. HNO_3, and heat. Solution is very quickly effected. Add 15 c.c. H_2SO_4 and boil to fumes. Cool, dilute to 90 c.c., and let stand a few minutes (boiling is unnecessary). Filter off the SiO_2 and $PbSO_4$, washing with small volumes of cold water.

To the filtrate add slowly, with stirring, Na_2S (10 per cent solution of crystals) until Cu is completely precipitated. About $\frac{3}{4}$ c.c. of Na_2S is required for each 1 per cent Cu present. If any CdS is observed, the Cu is completely precipitated. Boil about 2 min. The CdS dissolves again when boiled with this strength acid. Test solution with a drop of Na_2S, and filter hot, washing with hot water.

The paper containing the CuS is burned and Cu determined as usual.

Cool the filtrate, add 15 c.c. strong NH_4OH, dilute to 200 c.c., and determine Cd as in "Leach Solution."

The first filtrate from the CdS is boiled a few minutes to remove most of the H_2S, cooled, 5 c.c. H_2O_2 added, the Fe precipitated with NH_4OH, and Zn determined as usual. (See "Pure Electrolyte.")

Anode Scale From Cells

This consists chiefly of MnO_2 and PbO_2, and some Sb, probably as Sb_2O_5. Any coarse metal present should be screened out before analysis.

Antimony. To 10 or 20 g. of the scale add 100 c.c. distilled water and 15 to 20 c.c. H_2SO_4. Heat, gently at first, and add tartaric acid in small portions until the residue becomes rather light brown in color and the solution can be boiled without much foaming. Cool and filter on a Büchner funnel, washing with cold water.

To the filtrate add 60 to 80 c.c. of 3 per cent Na_2S, heat to boiling (take precautions against bumping), and treat the precipitate for antimony exactly as in "Pure Electrolyte."

Manganese. Scale to the amount of 0.295 g. is boiled with 20 c.c. of 1:1 HCl until dissolved. The chlorine may be boiled off, or it may be quickly destroyed by adding a little zinc dust, agitating a moment, and filtering off the lead sponge, etc. Mn is then determined by Volhard's method. If 1 c.c. $KMnO_4$ = 0.010 g. Fe, then 1 c.c. = 1 per cent Mn for 0.295 g. of ore.

Lead. Dissolve 1 g. of scale in HCl, take to fumes with H_2SO_4, and use Alexander's molybdate titration.

If preferred, the Mn can be determined in the filtrate from the $PbSO_4$.

Chemical Industry in Holland

The *Journal* of the Society of Chemical Industry concludes from articles in the *Schweiz Chemiker Zeitung* and the *Zeitschrift für Angewandte Chemie* that things are in a bad way with Dutch chemical industries. The year 1918 was a much better year than 1919. Large quantities of Chilean nitrate have been imported, which affects adversely the fertilizer manufacturers. Great fluctuations in prices make necessary immediate deliveries of all products. Many firms have difficulty in getting export permits, while no obstacles impede the importation of manufactured wares from central Europe and products of German origin are offered below the cost of raw materials. The paper industry did well during the war, but adverse conditions have intervened. Japan and America have captured a good part of the home and foreign markets. Coal is high and so is transportation, while labor is scarce and wages are high.

The manufacture of foods, condiments, wines, etc., has a better outlook. The sugar output is below normal owing chiefly to labor conditions. Margarine production has increased and the outlook is good. Brewers lack raw materials. Ample supplies are available to the cocoa and chocolate producers, but there is trouble about exports and it is feared that the old market for Dutch cocoa and chocolate will be captured by England and Switzerland.

Nitrate Industry in Chile*

Geography, Geology and Economic Situation of Chilean Nitrate — Present-Day Recovery of Nitrate From the Raw Material Is Far From Satisfactory and There Is Urgent Need for Improvements

By ALEJANDRO BERTRAND

CHILE'S nitrate deposits are limited to a strip of territory extending between the southern latitudes 19 deg. and 26 deg., i.e., for a length of 670 km. (about 400 miles) and along the seventieth meridian. The width of the deposits is very irregular. Thus in the northern districts of Tarapaca and Toco they are found in a series of separate but narrow strips of 5 km. (about three miles) maximum width. In the Antofagasta and Aguas Blancas districts they are scattered over polygonal areas of about 40 km. (25 miles) diameter, and those of the Taltal district are at least 40 km. wide. Fig. 1 gives the geographical location of the deposits.

Although geographically the location might indicate a tropical zone, in reality it is a veritable desert and offers a great contrast with the luxuriant vegetation, climate and hydrography of the Brazilian coast along the same latitudes. There is only one river worth mentioning in the nitrate region, the Rio Loa. The Cordillera de la Costa, sloping down to the coast, end in palisades of about 800 m. (2,600 ft.) high all along the Pacific coast and present only four outlets to the ocean: Quebrada de Tiliviche, to the Bay of Lisagua, located at latitude 19 deg., 33 min.; Rio Loa, the only water stream, at latitude 21 deg., 23 min., Antofagasta, at latitude 23 deg., 40 min., to which runs the Bolivian Railway, and the Quebrada de Taltal, at latitude 25 deg., 25 min.

There is not much rainfall in this region, but frequent clouds form heavy fogs, called *camanchacas*, which render the atmosphere damp and cover the soil with dew. The wind blows regularly from west to southwest, especially in the afternoons; it often reaches a great force and acts as a strong erosion factor. The temperature varies between 25 and 35 deg. C. (77 and 96 deg. F.) during the day and between 4 and 8 deg. C. (40 to 46 deg. F.) during the night. Freezing temperature occurs only exceptionally.

Many symptoms show the existence of a strong radioactivity in the nitrate region. The electric tension of the atmosphere is sufficiently strong to produce visible sparks when rubbing woolen clothes and to cause frequent telegraphic and telephonic disturbances.

Administrative Districts of the Nitrate Region

All the nitrate deposits are grouped into five administrative districts:

1. The Tarapaca district is the oldest and comprises a number of contiguous concessions. It is served by three railways (one broad gage and two narrow gage) connecting the workings with the harbor of Pasagua and Iquique. Branches extend to Junin and Caleta Buena. This district extends to about 21 deg. south latitude, south of which there is about 100 km. (62 miles) of land in which no nitrate deposits have yet been located.

2. The Toco district covers a length of about 70 km.

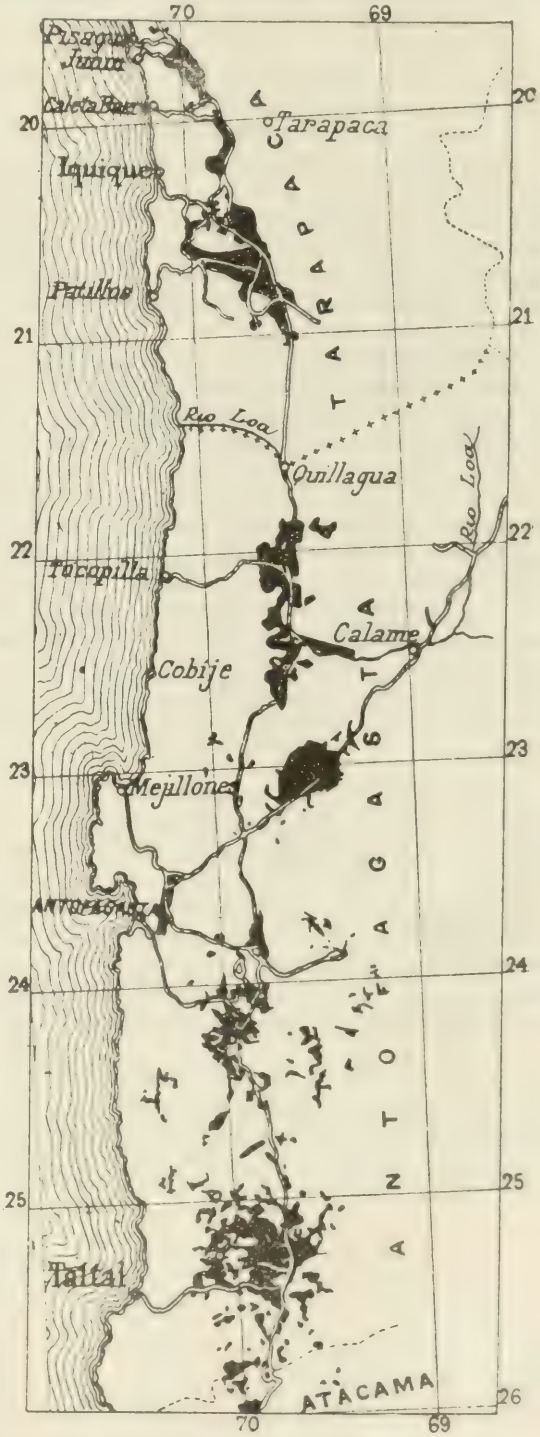

FIG. 1. GEOGRAPHIC DISTRIBUTION OF THE CHILEAN NITRATE

*Abstracts from a paper presented at the Nov. 26, 1919, meeting of the Société de Chimie Industrielle and printed in the January, 1920, issue of *Chimie et Industrie*.

FIG. 2. TYPICAL CHILEAN NITRATE PLANT

(44 miles) on the left bank of the Rio Loa. Its maximum width is about 20 km. (13 miles).

3. To the south of Rio Loa the nitrate deposits form two convergent series joined near the harbor of Antofagasta (latitude 23 deg., 38 min.). The first consists of scattered and insufficiently explored deposits in intermittent depressions, the second constitute the exploited saltpeter district of Antofagasta, whose maximum width is 15 km. (9.5 miles). It is served mainly by the Bolivian Railway.

4. Between latitudes 23 deg. 30 min. and 24 deg. 40 min. there are a number of groups of deposits, the principal group being the Aquas Blancas, 80 km. (about 50 miles) long, north to south, and 40 km. (about 25 miles) wide, east to west.

5. After a few kilometers of practically sterile land the nitrate deposits reappear, reaching the maximum width of 90 km. (56 miles) and ending at about south latitude 26 deg.

There are nine harbors to which the mined nitrate is taken for exportation. Table I shows the export tonnage capacity in metric tons of these harbors.

TABLE I. HARBORS AND THEIR EXPORT TONNAGE CAPACITY

Name	Yearly Capacity	Name	Yearly Capacity
Pisaqua	120,000	Mejillones	550,000
Junin	80,000	Antofagasta	480,000
Caleta Buena	310,000	Coloso	200,000
Iquique	700,000	Taltal	300,000
Tocopila	260,000		
Total			3,000,000

Table II gives the railways which reach these harbors, their gage, total length and average yearly tonnage.

The different railway gages are a great handicap to their efficient utilization, as can well be imagined.

Formation of the Nitrate Deposit

The nitrate deposits form generally horizontal beds covered usually by three distinct superposed layers. In some places one or even two of these layers may be missing.

TABLE II

Name of Railway	Width of Gage in Meters (1 Meter = 3.281 Ft.)	Length in Km. (1 Km. = 0.6214 Miles)	Nitrate Metric Tons (Metric Ton = 1.102 Short Tons)

Aqua Santa	0.76	116	300,000
Tocopilla Railways	1.07	122	260,000
Bolivia and Aquas Blancas Rys.	0.76	600	1,060,000
Taltal Railways	1.07	350	300,000
Longitudinal	1.00	630	
			3,000,000

A typical vertical section shows the following arrangement:

1. A layer of "chuca," which is a gray incoherent mass containing 45 to 65 per cent of quartzose silica and quite variable proportions of nitrates, chlorides, sulphates, carbonates, phosphates and iodates of potassium, magnesium, calcium, iron, aluminum, manganese, etc. The clear color indicates an appreciable quantity of crystallized sodium sulphate.

2. Next, a layer of "panqueque" (from the English pancake), a spongy, less friable variety of chuca, richer in calcium sulphate.

3. "Costra" (crust), next below, a kind of breccia of a color varying from dark brown to light gray. Costra contains from 40 to 70 per cent of insoluble matter. Among the soluble salts between 10 and 15 per cent is sodium nitrate. This layer is intimately associated with the following layer, which is the "caliche," the useful nitrate deposit.

Caliche, Its Composition and Properties

"Caliche" is an extremely complex and variable conglomerate. Its insoluble matter is cemented by a great variety of soluble salts. The proportion of insolubles varies from zero to 50 or even 60 per cent. The maximum percentages of the most important of the salts are shown in Table III. The salts for which the percentage is not indicated are usually present in small quantities or completely absent.

TABLE III. MAXIMUM OF THE MOST IMPORTANT SALTS CONTAINED IN CALICHE

	Per Cent Maximum		Per Cent Maximum
Sodium nitrate	80.0	Potassium sulphate	....
Potassium nitrate	5.0	Magnesium sulphate	....
Magnesium nitrate	....	Calcium sulphate	*10.0
Calcium nitrate	....	Aluminum sulphate	*8.0
Sodium chloride	60.0	Iron sulphate	....
Potassium chloride	....	Potassium perchlorate	....
Magnesium chloride	1.0	Sodium sulphonitrate	....
Calcium chloride	....	Calcium iodate and borate	....
Sodium sulphate	10.0	Sodium iodochromate	....

* Exceptional.

The caliches are classified according to their properties and their content in nitrates and other soluble salts.

Color. The color varies from white to black (manganic and ferrous), brown (earthy and argillaceous), sulphur yellow (chromous), orange (bromine salts), violet (iodine salts), etc.

Structure. The physical structure is extremely vari-

FIG. 3. VIEW OF A NITRATE DEPOSIT

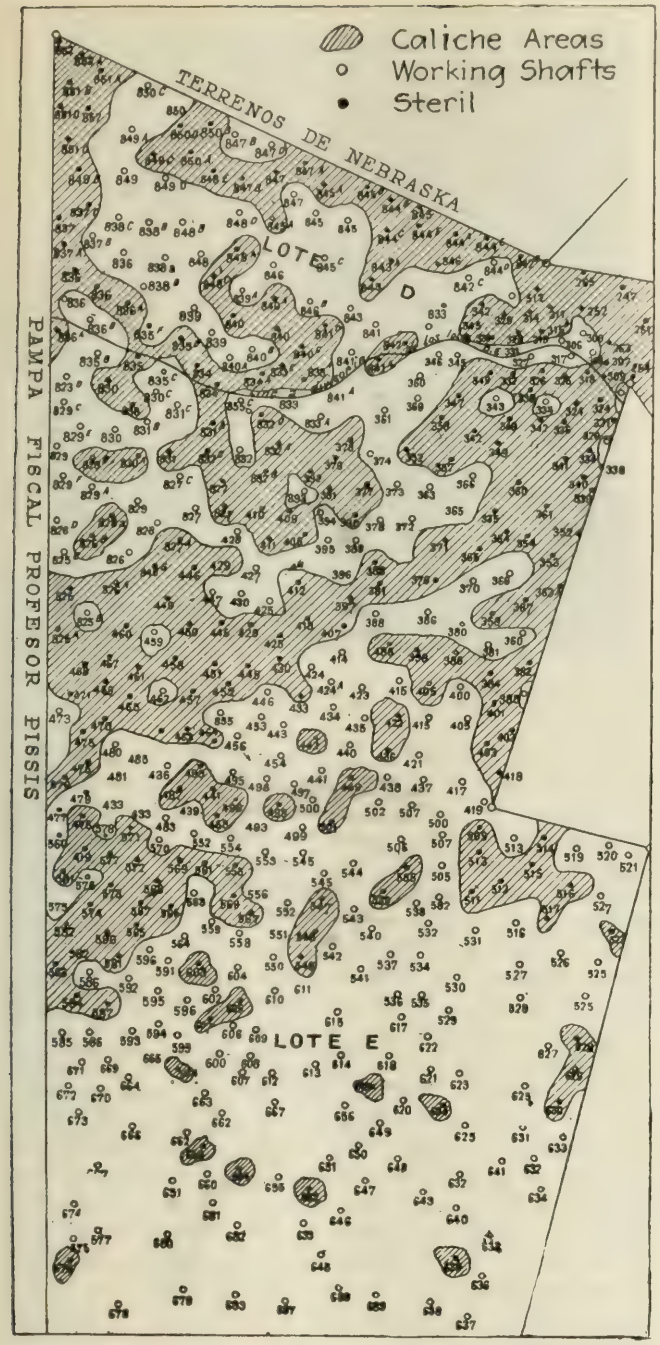

FIG. 4. PLAN OF A PROSPECTING CLAIM

able and has a great influence on the success of lixiviation. Breccia-like is the most common structure, with stony nodules of medium hardness. Others are porous, spongy, argillaceous and very compact (bony). Some are hydroscopic due to their contents of calcium nitrate.

Hardness. Hardness is a function of the structure. This property is of importance and serves to classify the caliche on the basis of the facility with which it is crushed.

Density. The density is not over 2.3 and can be as low as 1.9; for spongy caliche (45 to 52 per cent voids), it is 1.25 and even 1.0.

Substrata

Continuing in the typical vertical section there are usually three strata underlying the caliche, namely:

1. "Conjelo," which is breccia-like, the cement being sodium chloride and sulphate. The proportion of these salts may reach up to 75 per cent. Sometimes this conjelo is missing or is thoroughly intermingled with the caliche.

2. "Banco." This is also in the form of a breccia containing, besides sodium chloride and sulphate, some sodium nitrate, gypsum, etc.

3. "Coba." This is always present. It is composed of an earthy mixture with pebbles. It rests on volcanic rocks which constitute the skeleton of the Cordilleras.

It is impossible to fix the average thickness of the various layers. Caliche is never thicker than 2 m. (6.5 ft.), but coba can reach a thickness of 20 m. (65 ft.).

Prospecting for Nitrates

No plausible explanation of the origin of the deposits has as yet been given. This is a remarkable example of the imperfect human knowledge about nature's processes in the formation of a product existing on such a big scale as the Chilean nitrates.

Fig. 3 gives an idea of the usual appearance of a nitrate deposit.

A typical example of a prospecting claim is shown in Fig. 4. It is a portion of a plan published by the Chilean Government and shows the prospecting done since 1910. The government keeps geologic records on all the shafts.

The workmen have a practical way of judging the quality of caliche. They throw a small quantity of a pulverized sample on incandescent tinder. Caliche with less than 5 per cent nitrates does not give sparks, with 6 to 10 per cent nitrates the sparks are barely visible, with 10 to 20 per cent the sparks are more and more visible and numerous, with 20 to 30 per cent the sparks are visible in full sunlight. Caliche with more than 35 per cent nitrates will produce complete deflagration and flames appear. Sodium chloride decrepitates.

The prospecting holes are usually 100 m. (330 ft.) apart. Augers and scoops are used in the rudimentary prospecting work, explosives being employed but seldom.

Tables IV and V show typical examples of obligatory reports to be presented to the Chilean Government.

Separation of the Nitrate

The nitrate being present in the form of a mixture with other soluble salts and insolubles, its separation does not require any chemical reactions. Theoretically this separation appears to be extremely simple, because the only other soluble salt found in appreciable quantity in the caliche is sodium chloride and the solubility curves found experimentally and shown in Fig. 5 suggest an easy and purely physical separation of the nitrate from the chloride.

Experience has proved that the separation of the nitrate and chloride can be made to a limit of only 6 per cent chloride in solution by dissolving the caliche in boiling water. By cooling this solution to 0 deg. C. nearly 88 per cent of the nitrate free of chloride is precipitated.

This method of separation, although very simple in theory, is neither economical nor efficient, due to the great quantity of heat required and other physical conditions.

Methods of Separation

Two methods of operation are to be considered in practice. First, whether all the mass of caliche and insolubles shall be treated to boiling temperature with

the solvent. Second, whether there shall be a preliminary separation of insolubles at ordinary temperature and then treat the solution for the separation of nitrate by heating and cooling. The first method is the one which finds favor with the nitrate producers.

In the early days of the working of the Chilean nitrate (during the first half of the nineteenth century) only the caliche containing over 50 per cent nitrate (usually 60 to 80 per cent) was thought worth working.

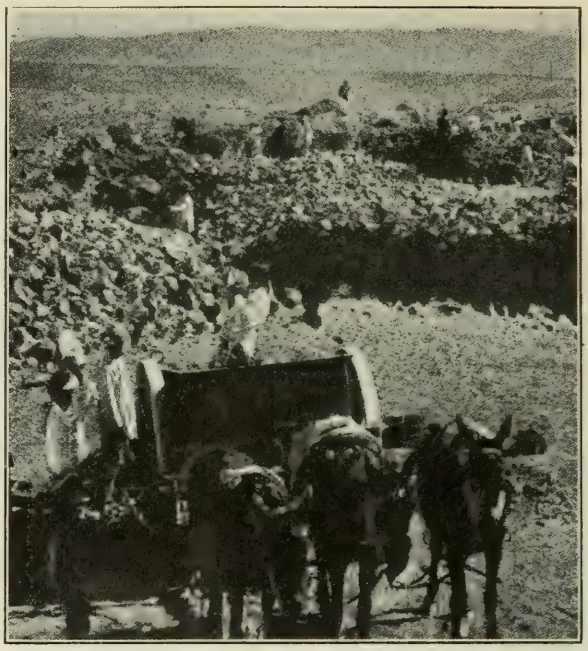

FIG. 6. METHOD OF TRANSPORTING THE CALICHE FROM THE MINE TO THE PLANT

This caliche was placed in round open tanks, treated with water, heated by open fire to boiling temperature; the solution decanted into settling tanks, where the insolubles in suspension and the sodium chloride were separated. The clarified solution was then transferred to crystallization vats or "bateas." The residue in the settling tanks usually retained from 15 to 25 per cent nitrate. This was sometimes re-treated with a new batch of caliche, but oftener it was considered as waste. Previous to 1856 about 200,000 tons of nitrate was obtained by this rudimentary method.

Beginning with 1856 improved methods of treatment were introduced. The first improvement was the substitution of steam heating for direct fire heating of the dissolving tanks. This improvement served two purposes, namely: To avoid burning the bottom of the tanks, and to agitate the mass by injection of live steam under a pressure of 3 to 4 kg. per sq.cm. (43 to 57 lb. per sq.in.). Tanks were, therefore, replaced by rectangular boilers of the Cornish type.

Next, direct steam heating was replaced by indirect steam heating.

These were the principal improvements during the period 1856-1876 when about 4,000,000 tons of nitrate was produced from caliche containing an average of 50 per cent nitrate.

The above rudimentary processes of operation resulted in excessive accumulation of residue "borras" from the

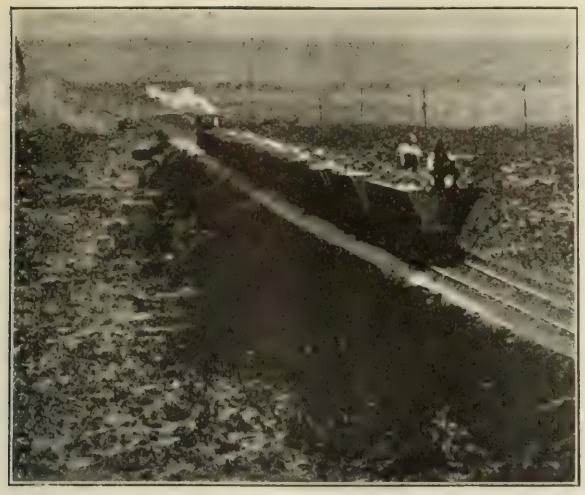

FIG. 7. RAIL TRANSPORTATION OF CALICHE

treatment, which residues contain up to 50 per cent of that nitrate originally in the caliche, in addition of the untreated waste "ripios," containing up to 30 per cent nitrate.

In 1876 the Shank process of lixiviation was introduced, thus enabling the treatment of caliches of poorer percentages of nitrate. Since first introduced it has been adopted by hundreds of plants and about 55,000,000 tons of nitrate has been thus extracted from the caliche.

This process, in which all the raw caliche and the solvent are brought to boiling temperature (the above-mentioned first method of operation) was a great improvement over the previous process during the early years of its introduction, because then the caliche treated contained on the average 50 per cent nitrate and only maximum 20 per cent of insolubles, and the useless heating of this last

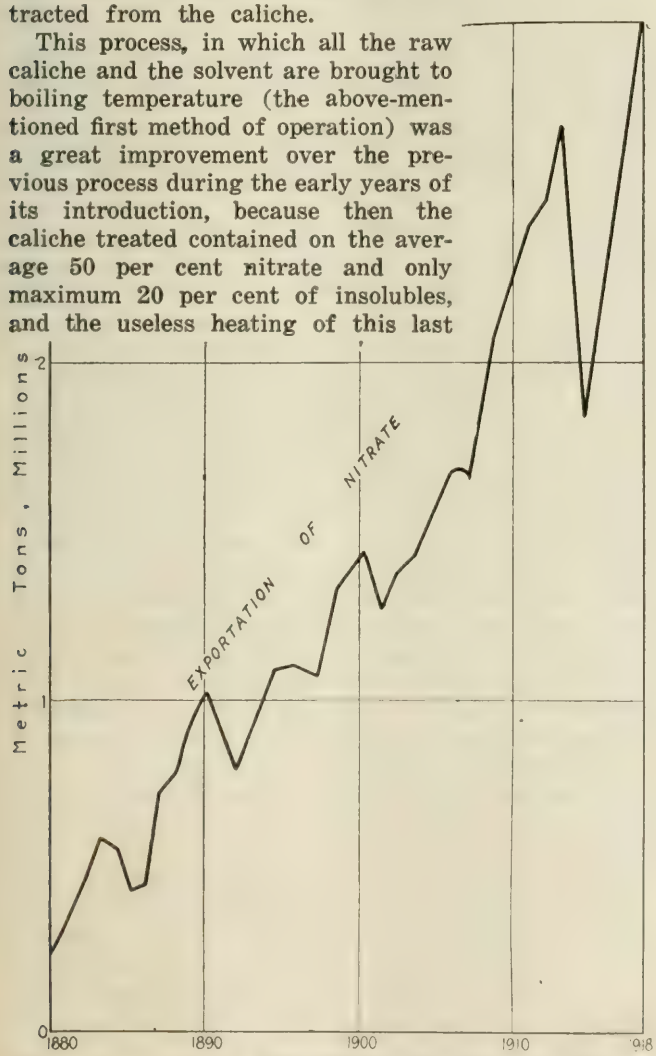

FIG. 8. PROGRESS OF THE EXPORT OF CHILEAN NITRATE FOR THE PERIOD 1880-1918

amount was relatively small. At the present time the Shank process is expensive and inefficient, because the caliche to be treated contains at the most 17 per cent nitrate and the insolubles reach about 60 per cent. These conditions require ever-increasing quantities of water per unit of nitrate produced and a corresponding increase in fuel consumed. Whereas in 1885 the separation of twelve units of nitrate required a consumption of one unit of fuel, now only five and in some cases as little as two and a half units of nitrate are produced per unit of fuel. Besides, the nitrate

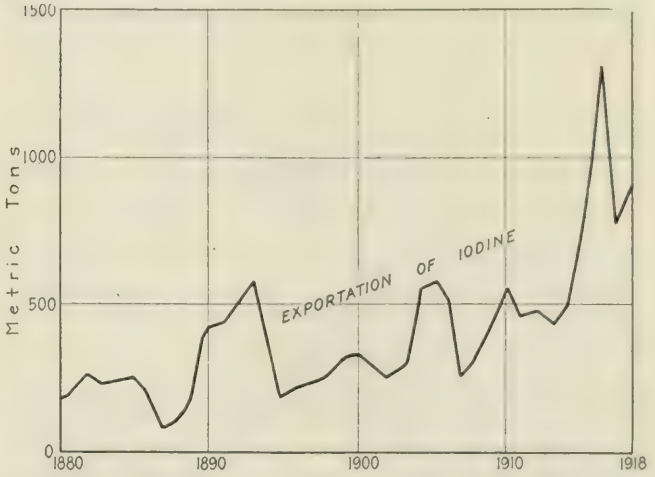

FIG. 9. PROGRESS OF THE EXPORT OF IODINE FOR THE PERIOD 1880-1918

recoveries by the process do not exceed 60 per cent, the average being 50 per cent, although the contents of the ripios have been reduced to even less than 5 per cent.

Need of an Improved Process

Up to the present the processes for the separation of the sodium nitrate from the caliche are based on the preparation of a hot saturated solution, from which the sodium nitrate crystallizes on cooling.

It is to be expected that other factors will be taken into consideration when improved processes are looked for, such as the use of reagents with catalytic effects.

Translator's Note: The author finishes by making a strong plea for technical research leading to a more efficient treatment of the Chilean nitrate, and states that in a subsequent paper he will dwell at length on the technologic questions involved in the treatment of caliche.

Industrial Growth in Norway

According to an official report bearing upon the industrial development of Norway from 1897 to 1917, the population of Norway increased from 2,157,000 to 2,629,000 inhabitants. Within the same period the number of industrial establishments increased from 9,422 to 32,174. During this period the increase of 22 per cent in the population of the country was accompanied by an increase of 112 per cent in the number of industrial workers of various kinds. The number of horsepower in Norway in 1917 was 1,613,283, as compared with 172,397 in 1897. The increased use of electricity for motive power is evidenced by the fact that in 1900 there were only 417 electric motors in all Norway, and their total capacity was only 4,121 horsepower. In 1917 there were 26,040 motors with a capacity of 342,251 horsepower.

Synopsis of Recent Chemical & Metallurgical Literature

Strength of Steel at High Temperatures.—G. P. McNIFF, in a written discussion, called attention to various independent researches corroborating the results obtained by H. J. French on the Tensile Properties of Boiler Plate at Elevated Temperatures, presented before the February meeting of the A.I.M.E., and abstracted in CHEMICAL & METALLURGICAL ENGINEERING for March 3, 1920, vol. 22, p. 393. He presented several photographs pertinent to this subject, of an experiment carried out at the Shelby works (Ellwood City, Pa.) of the National Tube Co., during 1913 and completed in January, 1914. One of the photographs showed a general view of the testing machine with the test piece in place surrounded by an electric tube furnace very similar to the set-up used by French. A Le Chatelier rare metal thermocouple was used for the temperature readings.

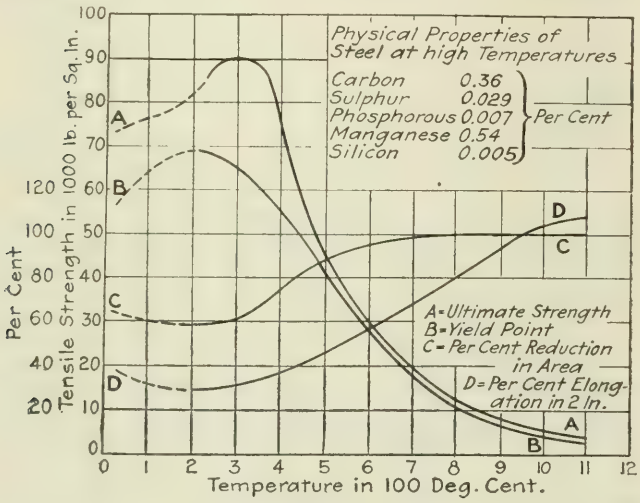

FIG. 1.

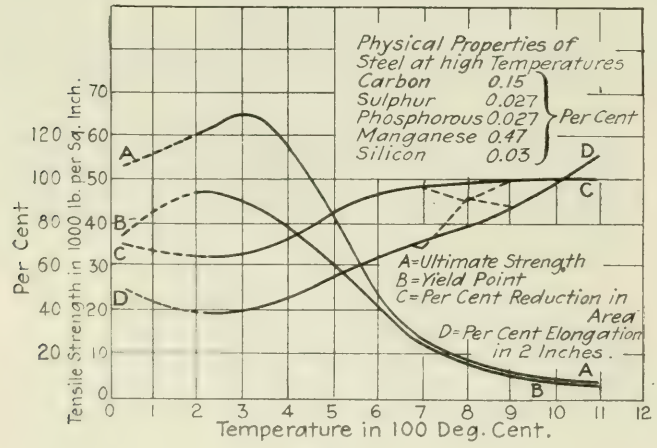

FIG. 2.

The material investigated was seamless tubing of several different carbon contents. A summary of the results obtained is shown on the curves attached. Fig. 1 gives results on a 0.36 per cent carbon steel, Fig. 2 on a 0.15 per cent (boiler tube grade) and Fig. 3 gives a comparison between the results of Kollmann[1] and Howard[2] previous investigators on this subject, results at the Shelby laboratory and those obtained recently by French.

In each case the results obtained are fairly concordant and seem to indicate that for all carbon steels their strength and characteristics at temperatures above normal are a direct function of these same characteristics at normal temperatures, and show no great variation with the carbon content.

FIG. 3.

H. D. Hibbard also mentioned that the Watertown Arsenal[2] had obtained very similar results a great many years ago.

British Blast-Furnace Practice.—According to the *Engineer*, March 5, 1920, vol. 129, p. 246, the paper which W. H. BUCKLEY, M.I. Mech. E., read on "British Blast-Furnace Practice" before the members of the Manchester Association of Engineers on Feb. 28 covered a large amount of ground, including descriptions of the furnace stack, stoves, and connections, dust catchers, charging arrangements, storage arrangements, pig-bed equipment, slag disposal, blowing plant, boilers, pumping plant, and gas-cleaning plant. The author said that the prevailing conditions in connection with British blast furnaces were open to considerable improvement in many directions. Future blast-furnace plants were not likely to exist as isolated units, but they would be operated in conjunction with and in close proximity to coke ovens and steel works. Thus the cost of handling and the loss of heat would be reduced to a minimum. Mr. Buckley said that electrical smelting on a large scale was not likely to be developed in the immediate future, until such times as our potential sources of power production were further developed. Enrichment of blast with oxygen had been tried in Belgium, but so far it was not a practicable success. The conservation of heat about a blast-furnace system was likely to receive more attention in future. Radiation losses could be considerably reduced if efficient means of insulation were provided. The recovery of heat from slag was also a question of vital importance, and so far only experimental work in that direction had

[1] *J. Frank. Inst.*, vol. 112, p. 241 (1881).
[2] *Iron Age*, April 10, 1890.

been carried out. If slag be granulated in water so that low-pressure steam be developed, such steam was not fit for use in low-pressure turbines, and an intermediate system of evaporation must be introduced, but there did not appear to be any reason why such dirty steam—which, incidentally, contained about 5 per cent of incondensable gases—should not be used for gas producers, in conjunction with air blowers. Potash was already recovered in large quantities from the fine dust in the gas, and the coarser dust—which had a comparatively low potash content—was likely to have a higher value in future, as some might be used on plants nodulizing fine ores. If waste heat could not be satisfactorily utilized for steam raising, there was a big field for the use of it in either drying ores or preheating blast, or air for combustion.

Nickel:Chromium Alloys and Thermocouples.—W. A. GATWARD recently read a paper on this subject before the Engineers' Society of Western Pennsylvania, in which he sketched the development and present status of this industry. Since both constituents melt at a high temperature, nickel takes carbon into solution, and chromium is easily oxidized, the alloys are very difficult to make. At no time in their development was it possible to predict the properties of untried combinations. Since 1906 about 2,000 tons of Ni:Cr metal has been used in the manufacture of heating devices alone. They actually contain varying percentages of Mn, Al, Fe or Si. Seven commercial alloys are described which may be used for heating elements, all of them quite durable at 800 deg. C. As the temperature goes up, their life rapidly shortens. The best of them, however, rapidly assume a closely-adhering coat of protective oxide. The author lists thirteen requisites of a good heating element. Principal among them is a low temperature coefficient. Experience shows that the presence of a cold body near a certain part of a heating element causes that portion to advance slightly in temperature. If the wire possesses too large a coefficient, this will cause that portion to become increasingly hotter until it melts.

Specific resistance should be high so that large sections and short lengths are possible for a given resistor. This is responsible for rugged elements, small in bulk, operating at a low temperature. It is desirable but apparently impossible to obtain a high heat conductivity at the same time, in order that the heat developed below the surface of the wire can be radiated effectively.

Nickel:chromium alloys have been invaluable in pyrometry, producing the first good positive element for base-metal couples. The secret of their success is proper protection, maintaining a strictly oxidizing atmosphere at all times. If graphite, carborundum or silfrax protecting tubes are used, a gas-tight lining should be provided. Luckily one of the same alloys, "chromel," is impervious to CO at working temperatures, and can therefore be used for this purpose.

If fusible material of almost any kind comes in contact with the hot wire, the protective scale is destroyed and a burn-out soon follows, from this cause if not from short-circuiting. Cyanide and sulphur fumes also cause rapid deterioration. Welding of clean surfaces may be done by feldspar and flame or an electric arc. Carburizing boxes or other sound castings can now be made weighing up to 1 ton and to 15 ft. long. Such pieces would have walls about 1 in. thick, or somewhat heavier than cast iron. They resist molten lead quite well.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Chlorpicrin.—The process of preparing chlorpicrin by treating picric acid with bleaching powder in the presence of water is difficult to control. The reaction is violent; the evolution of CO_2 and HCl and the absorption of these gases in the $Ca(OH)_2$ simultaneously produced cause foaming; the heating is excessive; the yield varies from zero to nearly theoretical without apparent reason; oxidation occurs, reducing the yield by the formation of resinous byproducts. ROBERT J. KING of Stamford, Conn., prefers the following: 10.8 parts of calcium picrate is dissolved in about 30 parts of water and added gradually to a solution of 88 parts of bleaching powder (35 per cent available chlorine) in 170 to 770 parts of water. A vigorous reaction takes place and the yellow color of the mixture rapidly disappears. The chlorpicrin is separated by steam distillation. (1,327,714; Jan. 13, 1920.)

Powdered or Granulated Aluminum.—When molten aluminum is subjected to violent agitation during cooling, at a temperature just below the melting point the mass will be broken up into granules. The degree of granulation may be controlled by the violence of the agitation. (1,327,743; LEWIS B. TERRETS, 2d, of St. Louis, Mo.; Jan. 13, 1920.)

Synthetic Ammonia.—When air or nitrogen is passed through a solution in which nascent hydrogen is being evolved, ammonia is formed. The nascent hydrogen may be produced electrolytically or by the action of acids or alkalis upon appropriate metals. (1,328,082; ROBERT F. GARDINER of Clarendon, Va.; Jan. 13, 1920; application filed under the act of March 3, 1883.)

Explosive.—There are two classes of high explosives similar in their explosive properties to existing standard grades of dynamite. The first comprises mixtures of small percentages of TNT with nitroglycerine for the production of the so-called low-freezing dynamite. These are expensive to manufacture, the liquid constituent tends to exude, and users are liable to contract severe headaches in handling the explosive. In the second class, low percentages of TNT are used with relatively large percentages of explosive salts having a high oxygen content such as ammonium nitrate, ammonium perchlorate, potassium chlorate, etc. These explosives are relatively insensible to detonation, are liable to become extremely hard in storage and are usually very dusty. A more satisfactory explosive is suggested by LEON O. BRYAN and WENDELL R. SWINT of Wilmington, Del. The following composition is typical: Nitrogycerine, 5 per cent; trinitrotoluol, 40 per cent; sodium nitrate, 55 per cent. Other examples are given which are equivalent to standard industrial dynamites. (1,327,859; assigned to E. I. du Pont de Nemours & Co.; Jan. 13, 1920.)

Calcium Carbide and Wood Distillation Products.—JAMES HENRY REID of Newark, N. J., describes a process for the production of wood distillation products and calcium carbide in one operation. A mixture

of sawdust and calcium oxide is heated in an electric furnace. At first products of the destructive distillation of the sawdust are obtained. Later, the temperature is raised until calcium carbide is formed. In a modification, coking coal is used instead of sawdust. A third patent describes an automatic controlling device for the furnace electrodes. (1,327,736; 1,327,737; 1,327,738; assigned to International Nitrogen Co.; Jan. 13, 1920.)

Purifying Ammonium Sulphate.—Damp crude ammonium sulphate crystals containing free acid, pyridine bases or sulphates of pyridine bases are placed in rotary container and heated to about 250 deg. F. by a current of hot air. Simultaneously, ammonia vapor is passed into the container. Ammonium sulphate is formed by neutralization of the free acid and the pyridine sulphates are decomposed. The pyridine bases are volatile at this temperature. The final product is dry ammonium sulphate, free from acid and pyridine. (1,328,342; WILLIAM A. SLOSS of Toledo, Ohio; Jan. 20, 1920.)

Sulphuric Acid Manufacture.—The efficiency of the chamber process is increased by removing the acid mist which forms in the first chamber and passing it through an electrical precipitator. The presence of the mist particles of nitrosyl sulphuric acid in the chambers tends to inhibit the completion of the reaction. Additional advantages claimed by HARRY V. WELCH of Los Angeles, Cal., are: Circulation of the gases in the chamber by withdrawing the vapors at one end of the chamber and returning them (after having passed through the precipitator) at the opposite end; cooling of the gases so that the heat of reaction does not raise the temperature above the optimum. Chamber acid flows through the precipitators and the strong acid thus formed is fed to the Glover tower. (1,328,552; assigned to International Precipitation Co.; Jan. 20, 1920.)

Artificially Cooled High-Frequency Coil.—The temperatures attainable in the Northrup induction furnace are materially increased by making the inductor coil hollow so that it may be cooled by water, oil, etc. Temperatures above 2,500 deg. C. may be reached. (1,328,336; EDWIN F. NORTHRUP, assignor to the Ajax Metal Co.; Jan. 20, 1920.)

Reduced Sulphite Waste Liquor.—Commercial neutral waste sulphite liquor of 30 deg. Bé. is acidified with 1 or 2 per cent of H_2SO_4 and iron filings or iron wire added. The reduction may be hastened by adding a little copper to form a couple. The reduced liquor, after removing undissolved iron and iron salts, is evaporated to 20 to 30 deg. Bé. It may be used as a dye, producing shades of greenish brown or unmordanted wool. The liquid also has considerable insecticidal value. It may be used with the usual spraying apparatus. Retaining some of the physical properties of the original sulphite liquor, it adheres well to leaves, vines, etc. (1,327,862; FRANK E. COOMBS of San Francisco, Cal.; Jan. 13, 1920.)

Sodium Ferricyanide.—The process which is commonly used for the manufacture of potassium ferricyanide from potassium ferrocyanide—namely, oxidation by means of a halogen according to the equation:

$$2K_4Fe(CN)_6 + Cl_2 = 2KCl + 2K_3Fe(CN)_6$$

fails when applied to the corresponding sodium salts. It is very difficult to separate the sodium chloride and sodium ferricyanide by fractional crystallization. ROGER WILLIAMS of Providence, R. I., has found that sodium chloride dissolves readily in anhydrous liquid ammonia while sodium ferricyanide does not. Accordingly, when the solution of the two salts is evaporated to dryness and the residue treated in a suitable apparatus with liquid ammonia, the sodium chloride is completely extracted. The final residue may be dissolved in sufficient water to form a saturated solution and allowed to crystallize. To favor the production of particularly large crystals, some additional water may be gently poured upon the top of the concentrated solution, which when allowed to stand will then deposit large red crystals. The ammonia is recovered from the solution of sodium chloride by heating, cooling and compressing. In order to reduce losses of ammonia to a minimum the apparatus employed should be air-tight. (1,328,938; assigned to Nitrogen Products Co.; Jan. 27, 1920.)

Calcium Fluoride.—When prepared by the interaction of dilute solutions of calcium chloride and hydrofluoric acid, the precipitate of calcium fluoride is slimy and great difficulty is experienced in filtering and washing. By using concentrated solutions, WALLACE S. CHASE of Lakewood, Ohio, finds that the character of the precipitate is greatly improved. If the precipitate is dried at a temperature between 100 and 150 deg. C. and then pulverized, washing and filtering may be accomplished with ease. This process of preliminary drying is also applicable to other slimy precipitates. (1,329,072; assigned, by mesne assignments, to National Carbon Co.; Jan. 27, 1920.)

Stabilizing Nitrostarch Explosives.—There are certain substances, such as rosaniline base, and diphenylamine, which are well recognized as stabilizing agents in connection with nitrocellulose products. Owing to the greater ease with which nitrostarch tends to colloid, the introduction of these materials into the manufacture of nitrostarch explosives has been limited, and accordingly the use of these valuable stabilizing agents has in a measure been prevented. The colloiding action of these stabilizers may be prevented by dissolving them in a heavy mineral oil before adding to the explosive. A further advantage is the uniform distribution of the stabilizer. (1,329,211 and 1,329,212; WALTER O. SNELLING and WILLIAM R. LAMS of Allentown, Pa., assignors to Trojan Powder Co.; Jan. 27, 1920.)

Acetone and Butyl Alcohol by Fermentation Process.—The process of fermenting carbohydrate material to form acetone and butyl alcohol, using bacteria of the amylobacter group, is accelerated by a preliminary treatment with molds or enzymes having a strong proteolytic action. The mold used must not produce organic acids or alcohols which would interfere with the subsequent fermentation. CHARLES WEIZMANN and GEORGE A. HAMLYN of London, England, cite the following example: A sterilized mash prepared from rice, corn or other grain is inoculated with *Aspergillus oryzae*, which is allowed to grow for three or four days at 30 to 37 deg. C. The mash is then inoculated with cultures of amylobacter, which normally do not produce active fermentation. Fermentation sets in very rapidly and continues for 48 to 60 hr. The product is then distilled. The yield of acetone and butyl alcohol varies from 15 to 20 per cent of the weight of grain used. (1,329,214; Jan. 27, 1920.)

Current Events
in the Chemical and Metallurgical Industries

Chemical Warfare Service

None of the opposition which was manifested in the committee against a separate Chemical Warfare Service was voiced in the House when that section of the Army reorganization bill came up for consideration. The committee's report for a separate Chemical Warfare Service was adopted without a record vote.

In the bill proper the duties of the Chemical Warfare Service were not prescribed. This was remedied by an amendment which reads as follows:

> The duties of the Chemical Warfare Service shall comprise the investigation, development, manufacture, or procurement and supply to the Army of all smoke and incendiary materials, all toxic gases, and all gas-defense appliances; the research, design, and experimentation connected with the chemical warfare and its matériel; and chemical projectile filling plants and proving grounds; supervision of the training of the Army in chemical warfare, both offensive and defensive, including the necessary schools of instruction; reorganization, equipment, training, and operation of special gas troops.

As passed by the House the Chemical Warfare Service is to consist of one chief, with the rank of Brigadier General, ninety officers, in grades from Colonel to Second Lieutenant, and 1,500 enlisted men. An effort by Representative Dent to amend the bill so as to designate the specific number of officers of each grade, as well as the number of chemical engineers to be employed, was lost. In explaining his amendment Mr. Dent pointed out that the Chemical Warfare Service is a development of the war and that "if it has any unfriendly administration we all know that unless the personnel is fixed the Service itself is liable to prove a failure."

Mr. Dent was asked by one of the members of the House how the Service would secure its expert chemists, since the bill provides that the officers must have served during the war in order to be entitled to a commission. In reply Mr. Dent expressed the opinion that it would be necessary to get chemists from outside the military service, which he thought would be precluded by the wording of the bill. He used that as an argument for recommitting the bill to the committee so that its defects might be remedied. This the House declined to do, however.

In the course of the discussion several tributes were paid to General William L. Sibert, who until recently was the head of the Chemical Warfare Service. That the House is not satisfied with the explanation of the Secretary of War that General Sibert's removal from the Chemical Warfare Service to be commander at Camp Gordon was simply to prevent a loss of one grade in rank became very evident during the debate. It was plainly intimated that the real reason for the change in assignment, in the opinion of some members, was due to its criticism of the legislation as recommended by the General Staff. Mr. Dent declined to express himself in that connection, but said it is his personal opinion that the Chief of the Chemical Warfare Service should be a Major General rather than a Brigadier General.

Despite the pressure for a vote on the bill Mr. Dent insisted on reviewing the accomplishments of General Sibert as head of the Chemical Warfare Service, which he referred to as one of the greatest developments of the war. His reference to General Sibert is as follows:

> A native Alabamian, William L. Sibert graduated from West Point with high distinction. He was assigned to the Corps of Engineers. He performed valuable river and harbor work upon the Ohio River in particular. Without any political pull, when the Panama Canal was to be constructed, President Roosevelt selected him as one of the commissioners to build the canal. He was assigned to the specific duty of constructing the Gatun Dam and Locks. He dammed the Chagres River when the late Senator Morgan, of Alabama, who for years had advocated some form of transcontinental canal, said that that river could not be dammed. After his service there the Congress of the United States, along with the other members of that commission, extended to him its thanks, authorized a promotion above the grade that he occupied, and further authorized his voluntary retirement before reaching the age of sixty-four. This he has continuously refused to accept. After his work with the Panama Canal he was assigned to the Pacific coast in charge of the Coast Artillery as a line officer. He succeeded well and ably in that work. When the war broke out he was assigned to the organization and training of the first division that went to France.
>
> He organized it, trained it, and carried it to France. He commanded that division in France and was for a time placed second in command to General Pershing. For some reason he was returned to this country and placed temporarily in command of the Southeastern Department at Charleston, and then when the Chemical Warfare Service was established the Secretary of War very properly called General Sibert to take charge of the organization and development of that branch of the service. General Sibert took charge of it, developed it during the war, and has made out of it, in my humble judgment, one of the greatest developments that the war established.

Tungsten Bill Reported to Senate

Arguments to the effect that the tungsten resources of the United States are so limited that the existing deposits should remain untouched as a safeguard in a future emergency evidently were not accepted by the Senate Finance Committee, as it has reported favorably to the Senate a tariff bill which is believed to grant sufficient protection to permit the development of domestic mining industry. The Senate committee from its investigation found the cost of domestic production averaging $13 per unit. The data showed foreign costs to be from $2 to $4 per unit. It pointed to the fact that tungsten was selling at New York from $6 to $7.50 per unit and that fully 50,000 units per month are being imported, duty free. As the domestic mines cannot meet those prices, all of them are closed and prompt action is necessary to prevent the destruction of the industry, the committee reports. It is the belief of the committee that eventually the entire domestic requirements for this metal can be met from our own mines. During the period of development, it is pointed out, a substantial revenue should be received by the Government from importations of ore.

Fifth Annual Meeting of T. A. P. P. I.

The fifth annual meeting of the Technical Association of the Pulp and Paper Industry will be held in New York on April 13, 14 and 15. The business and technical sessions will be held at the Waldorf-Astoria Hotel and the annual banquet will take place at the Hotel Astor. The order of meetings will be as follows:

Tuesday, April 13, 9:30 a.m.

Meetings of standing committees in Myrtle Room and Room 151, Waldorf-Astoria.

First General Session

Wednesday, April 14, 9:30 a.m., Myrtle Room

Business meeting.

Appointment of committee to nominate officers to serve during the ensuing year.

The reports of committees will be received in the following order:

Abstracts of Literature—Ross Campbell, chairman.

Bibliography—Henry E. Surface, chairman.

Groundwood—William A. Kelly, chairman.

Heat, Light and Power—Edward P. Gleason, chairman.

Paper Testing—Frederick C. Clark, chairman.

Pulp and Paper Machinery—George R. Wyman, chairman.

Soda Pulp—Martin L. Griffin, chairman.

Standard Methods of Testing Materials—E. C. Tucker, chairman.

Sulphate Pulp—Olai Bache-Wiig, chairman.

Sulphite Pulp—Herbert G. Spear, chairman.

Vocational Education—George E. Williamson, chairman.

Second General Session

Wednesday, 2 p.m., Myrtle Room

Reading and discussion of special papers:

Some Further Mill Trials on the Pulping of Second Cut Cotton Linters, by Otto Kress and Sidney D. Wells.

Testing Tearing Strength of Paper With the Elmendorf Tearing Tester, by Armin Elmendorf.

Fuel From Sulphite Waste Liquor, by George Barsky and Ralph H. McKee.

Grinding Woodpulp Efficiently, by A. F. Meyer.

Advantages of Liquid Sulphur Dioxide for Sulphite Pulp Manufacture, by Vance P. Edwardes.

3:30 p.m., Room 151

Symposium on Rag Selection and Cooking. E. C. Tucker, chairman:

1. Selection of rags and their standardization.

2. Cooking of rags: (*a*) Reasons for cooking and objects accomplished; (*b*) the cooking liquor; (*c*) the rotary boiler and drive, with special reference to any recent improvement, power consumption, etc.; (*d*) the factors of time and pressure and how cooking is influenced by them; (*e*) the washing of rags in the boiler and their handling from boiler to washer.

Wednesday Evening, April 14

Annual banquet at Hotel Astor; reception at 7 p.m., dinner at 7.30 p.m.

Guests and speakers: Raymond S. Hatch, president; Judge Charles F. Moore, toastmaster; Joseph W. Fordney, chairman of the Ways and Means Committee, House of Representatives; Prof. William H. Walker, Massachusetts Institute of Technology; Prof. Charles Baskerville, College of the City of New York; George Carruthers, president of the Interlake Tissue Mills, Ltd., Toronto, Canada; Henry W. Stokes, president of the York Haven Paper Co., York Haven, Pa.; John Stadler, Belgo-Canadian Pulp & Paper Co., Ltd., Shawinigan Falls, Canada; John E. Alexander, Nekoosa-Edwards Paper Co., Port Edwards, Wis.; Evan Davies, New York; Howard S. Neiman, New York.

Third General Session

Thursday, April 15, 2 p.m., Myrtle Room

A short session will be held prior to recessing for attendance on the general meeting of the American Paper and Pulp Association in the Astor Gallery.

Nomination and election of officers.

Fourth General Session

Thursday, April 15, 2 p.m., Myrtle Room

Reading and discussion of scientific papers:

Possibilities of Developing a More Efficient Method of Extracting the Soda Salts From Black Ash, by George M. Trostel.

Improved Equipment for the Sulphite Mills, by E. R. Barker. This paper will describe a new type of limestone acid system; a new apparatus for automatic melted sulphur feed; an automatic alarm to show sublimed sulphur; a device for regulating the strength of acid in Jenssen towers, and a system for controlling automatically the strength of acids from milk of lime systems.

Methods of Cooking Control, by W. E. Byron Baker.

Limestone Analysis and Evaluation for Bisulphite Liquor Manufacture, by W. E. Byron Baker.

Sectional Individual Motor Drive for Paper Machines, by Stephen A. Staege.

The Application of Pragmatic Philosophy to the Papermaking Industry, by John W. Brassington.

Some New Methods of Waste Sulphite Liquor Recovery, by Walter H. Dickerson.

2 p.m., Room 151

Symposium on the extent to which the jordan can replace the beating engine in the production of paper. The discussion will be led by W. L. Nixon, of the Chemical Paper Manufacturing Co., and Max Zimmerman, of the Charles Boldt Paper Mills, will contribute a special paper on the subject.

A symposium is planned for the discussion of black liquor recovery with special regard to the most durable method of lining the smelters used in the sulphate recovery process. The discussion will be led by G. F. Enderlein, of the Brompton Pulp & Paper Co., Ltd., East Angus, Que., and R. M. Radsch, of the Thilmany Pulp & Paper Co., Kaukauna, Wis.

Proposed Tariff on Antimony Compounds

New tariff duties on antimony and antimony salts are proposed in a bill just introduced by Representative Watson of Pennsylvania. Antimony as regulus or metal and matte containing antimony, but not containing more than 10 per cent of lead, is to be dutiable at 10 per cent ad valorem. His bill also provides for a 25 per cent ad valorem duty on antimony oxide and a duty of 7c. per lb. and 45 per cent ad valorem on antimony salts, titanium salts, hydrosulphites, sulphoxylates and artificial bases.

Meeting of the California Section of the American Chemical Society

At the regular meeting of the California Section of the American Chemical Society held Friday, March 26, at the Engineers' Club, San Francisco, two interesting papers were presented. The first, by Dr. L. H. Duschak of the United States Bureau of Mines, on "The Chemical Basis for the Volatilization Process as Applied to Silver Ores," and the second, by Dr. W. H. Rodebush, Fellow of the National Research Council, on "Industrial Alcohol in the Industries."

Dr. Duschak reported experiments conducted at the Bureau of Mines Station in determining the vapor pressure of silver chloride at high temperatures from 980 to 1,140 deg. C. Vapor pressure of silver and of silver sulphate were also studied, as well as the possible formation of silver silicate. The experiments showed that there was no evidence of the formation of silver silicate under furnace conditions as had previously been indicated by some investigators. Investigation showed that the presence of oxygen and water vapor was necessary for a satisfacory volatilization and also that it was necessary to have an excess of chloridizing agents present to produce what Dr. Duschak termed "protective chlorination," in order to prevent the reduction of the chloride formed to the oxide or to the metal.

Dr. Rodebush reviewed the sources of supply of industrial alcohol, together with its use in the arts. He suggested the possible development of agriculture in the tropics for the production of sugar-bearing plants as a source of future supply. He reviewed the industrial possibilities of water-free alcohol and the production of ethylene-glycol and of ethyl acetate from alcohol and the use of these in industry. Ethylene is a more satisfactory substance than acetylene for use in welding. Attention was called to the fact that ethyl acetate is being used extensively as a solvent.

Cleveland Section Meeting, A. C. S.

At the March meeting of the Cleveland Section, American Chemical Society, held March 19, Dr. Charles L. Parsons gave an extremely interesting illustrated lecture on "Nitrogen Fixation." Before commencing his talk Dr. Parsons outlined the aims of the Society and told how it had become a powerful force in national affairs during the past three or four years. He cited, as an instance, the recent establishment by Congress of the Chemical Warfare Service as a separate corps against the wishes of the General Staff.

In his lecture he outlined the various processes of nitrogen fixation that held commercial possibilities in this country and described some of the plants that had been erected during the war, especially the ones at Muscle Shoals and at the Solvay plant at Syracuse. Dr. Parsons expressed the opinion that the Haber and the sodium cyanide processes seemed to offer the greatest possibilities for future development and that with the development the farmers should be educated to the use of the various nitrogenous fertilizers.

Chemical Warfare Service Stops Recruiting

No enlistments are being accepted for the Chemical Warfare Service, the Adjutant General of the Army announces, "as this branch is filled by men who are securing advanced instruction in chemistry."

Protection for Trademarks in Foreign Countries

Legislation which will bring about much needed protection to American trademarks and commercial names abroad has been approved finally by both houses of Congress and is before the President for his signature. It is expected that the President will sign the measure.

The legislation referred to is the ratification of the Buenos Aires convention, which allows American interests to file their trademarks and commercial names in an international bureau at Havana, thereby precluding separate registration in any of the South American republics.

The Latin-American countries already have ratified the convention. The bill also carried an amendment to the trademark act of Feb. 20, 1905, which adds to that law the following words:

> And if any person or corporation shall have so registered a mark upon the ground of said use for ten years preceding Feb. 20, 1905, as to certain articles or classes of articles to which said mark shall have been applied for said period, and shall have thereafter and subsequently extended his business so as to include other articles not manufactured by said applicant for ten years next preceding Feb. 20, 1905, nothing herein shall prevent the registration of said trademark in the additional classes to which said new additional articles manufactured by said person or corporation shall apply, after said trademark has been used on said article in interstate or foreign commerce or with the Indian tribes for at least one year, provided another person or corporation has not adopted and used previously to its adoption and use by the proposed registrant, and for more than one year such trademark or one so similar as to be likely to deceive in such additional class or classes.

Chemical Engineering at University of Nebraska

The department of chemistry of the University of Nebraska has introduced some new courses in practical chemistry, which have been working out very successfully. These courses were opened last September. For some years this department was not in position to offer technological chemical courses, because of lack of facilities. Now the department is housed in a very fine new laboratory and the chairman of the chemistry faculty, Dr. F. W. Upson, set about arranging for courses devoted to chemical engineering subjects. The department has also put in a course in "Oil and Gas" which is primarily for geologists. This work is in charge of Associate Professor C. J. Frankforter. Mr. Frankforter returned to the department last September, after having served twenty-two months in the Army.

Chemistry of the Earth's Crust

In an address before the Geological Society of Washington on March 24, Dr. H. S. Washington presented a recalculation of the composition of the earth's crust and the density of the earth over different areas. A very striking relationship was pointed out for the first time by Dr. Washington between the average density of the earth and the elevation above sea level. Several charts showing the relationship for both northern and southern hemispheres give almost complete agreement between the average analyses and the altitude figures. A correlation with the variation of density as measured by the pendulum method by Bowie was also given.

A new classification of the elements in the periodic system was presented, showing a systematic relationship between the elements which occur mainly in minerals and those which occur in rocks.

Civil Service Examinations

The following examinations are announced by the Civil Service Commission:

Assistant Examiner, Patent Office.—Examinations will be held April 7 to 9, May 5 to 7 and June 9 to 11 at places specified in Form 1237. Entrance salary, $1,500 a year, with temporary increase of $240 a year.

Mold Maker (Optical Glass or Ceramics).—Two vacancies exist in the Bureau of Standards; one in the position of mold maker, optical glass, at $1,680 a year in Washington, D. C., the other in the position of mold maker, ceramics, at $1,380 a year for duty in Pittsburgh, Pa. Apply on Form 1312 before April 20.

Petroleum Engineer and Assistant Petroleum Engineer (Oil and Gas Production).—Salaries, $3,000 to $4,500 and $2,100 to $3,000 a year, respectively. The closing date for receipt of applications (Form 2118) has been postponed from March 16 to April 27.

Laboratory Assistant.—Vacancies in Bureau of Construction and Repair, Navy Department, at $5.20 per day and at the U. S. Navy Yard, Washington, at $6 per day will be filled from examinations held at the usual places April 28 and 29, June 9 and 10 and July 21 and 22.

Mechanician and Laboratory Assistant.—For duty at Berkeley (Cal.) Station of Bureau of Mines at $5.25 per day. April 28 and 29, 1920.

Physicist.—Applications will be received until further notice for positions in Bureau of Standards (assistant physicist, $1,400 to $1,800 a year; associate physicist, $2,000 to $2,800 a year) and in the Signal Service of the War Department at $1,500 to $1,800 a year.

Laboratory Assistant.—Applications will be received until further notice for position in Bureau of Standards at $1,200 to $1,380 a year.

Technologist.—Positions of associate technologist, $2,000 to $2,800 a year, and assistant technologist, $1,400 to $1,800 a year, in the Bureau of Standards will be filled from this examination. Applications will be received until further notice. Applicants must qualify in rubber, leather, paper, textile, oil or general technology.

In all the positions mentioned, appointees at annual compensation of $2,500 or less, whose services are satisfactory, may be allowed the temporary increase of $20 per month granted by Congress.

Dr. Whitney to Receive Chandler Medal

At a meeting to be held in Havemeyer Hall, Columbia University, at 8:15 p.m. on April 27, the Chandler medal will be presented to Willis Rodney Whitney, director of the research laboratory of the General Electric Co. Dr. Whitney will speak on "The Littlest Things of Chemistry."

The Charles Frederick Chandler Foundation was established in 1910 by friends of Prof. Chandler. The income from this fund is used to provide a lecture by an eminent chemist and to provide a medal to be presented to the lecturer in further recognition of his achievements in science. Previous lecturers on this foundation were Dr. L. H. Baekeland and Dr. W. F. Hillebrand.

Navy Releases Sodium Nitrate for Fertilizers

To assist in relieving the shortage of fertilizing materials the Secretary of the Navy has authorized the sale of 9,925 tons of its surplus of sodium nitrate.

No Liquidation of American Property in Germany

From the first issue of *Transatlantic Trade*, the official organ of the American Association of Commerce and Trade in Berlin, we quote the following note relative to the way in which Germany handled American property during the war:

"There have been so many false reports circulated in the United States as to what happened to American property in Germany during the war that a statement of actual facts seems necessary. American commercial interests were neither liquidated nor sold. Personal and household property of our citizens underwent no change whatever; today American citizens are in full possession of their property. Former members of the American colony, now in the United States, will be glad to learn that their property is intact; much of such property was stored in warehouses at the beginning of the war in 1917. In several cases the storage rent has not been paid, but the German agencies to whom it was entrusted are still carrying this property pending claims of the rightful owner. American business houses in Germany were put under a controller at a salary in keeping with the firm's financial capacity. The principal functions of this controller were to watch the company's finances, and to exercise a general control over the undertaking. His instructions prevented him from injuring the American features of the undertaking.

"In several cases the action of the controller has given rise to criticism. Reference is made to those American firms with headquarters in Berlin and a large network of agencies scattered over the country. With importation of goods cut off, it seemed advisable to the controller, in the interests of the company, to close up these agencies in other cities which involved a large expense in office and shop rent and salaries. This act has been looked upon by the head offices in the United States as a partial liquidation, but the controller defends the act by stating that it was in the company's interests. With the head office intact; he claimed that agencies could be reopened after the war when goods were available: German firms were doing the same."

Freight Rates on Sodium Nitrate

On complaint of the General Chemical Co., the Interstate Commerce Commission has handed down an important decision reducing the rates which have been charged on sodium nitrate imported from Chile, from north Atlantic ports to points in the Middle West. The Commission prescribes rates which are to govern in the future, as follows: New York to Hegewisch (a Chicago rate point) 33c. per 100 lb.; New York to Willow, Ohio, 71 per cent of the Hegewisch rate; Philadelphia and Baltimore to Hegewisch and Willow, and from Baltimore to Ivorydale, 100, 71 and 87 per cent, respectively, of the New York-Hegewisch rate. These rates apply to carload lots and do not include the regular port differentials.

Idaho Phosphate Rock for the Orient

A recent development in the utilization of the phosphate deposits of the West is to be noted in a contract for the shipment of 35,000 tons to Japan. The rock will be mined at Paris, Idaho, and shipped via Portland, Ore. This is to be considered in the light of a preliminary shipment and it is estimated by the Portland Chamber of Commerce that about 300,000 tons of the rock will be thus exported from that port this year.

Engineering and Accident Prevention

For the purpose of bringing the safety movement and the engineering world more closely together, the Engineering Section of the National Safety Council has called a conference of all persons interested in engineering and accident prevention, to be held at the Engineering Societies Building in New York City, April 27. The morning session will first take up the relationship of safety and engineering efficiency—the question whether, apart from its human values, safe operation of a factory or a railroad is in truth inseparably connected with efficient operation. If this question can be answered in the affirmative, the answer will prove conclusively that safety is worthy of greater attention from engineers and that it deserves a place in the curriculum of engineering colleges. This topic—safety education in technical schools—is the next subject on the program. The afternoon session will be devoted to safety standards: first, the present movement for uniform standards; second, the National Safety Council's part in this movement.

Patent Royalties for Government Employees

Government employees are to receive a portion of any royalties which may accrue from patents which may be made of discoveries or inventions made or developed on Government time, according to the provisions of a bill which just has passed the Senate. The Federal Trade Commission is assigned the duty of administering the patents for the benefit of the public. The President is to fix the percentage which is to be allowed the employees.

Water-Power Bill Delayed

Meetings of the conferees on the water-power bill again are being held, but little progress is being made in adjusting the differences between the bills as passed by the Senate and by the House. Some fear protracted delay before a compromise can be agreed upon.

Book Reviews

INORGANIC CHEMICAL SYNONYMS. By *Elton R. Darling, Ph.D.*, in charge of industrial chemistry department, Newark Technical School. 100 pp. New York: D. Van Nostrand Co. Price, $1.

In the commercial world, chemical products are frequently known by names which have no apparent connection with scientific nomenclature. Furthermore, these colloquialisms vary according to geographical location, so that a single chemical may be represented by as many as twenty different terms. Most chemists will recall instances in which a great deal of time and effort was expended in search of the meaning of some strange new compound, only to find that it was an old laboratory friend masquerading under a trade name.

In this book, the author has gathered together over seven hundred synonyms for one hundred and twenty compounds of the following elements: Aluminum, antimony, arsenic, barium, bismuth, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, nickel, potassium, silver, sodium, zinc, hydrogen. A separate section is devoted to each element in the order given, with a few introductory paragraphs giving the physical properties and a brief review of the history of the element. Under iron, as an example, we find that ferric oxide has the following synonyms: Ferri oxidum, ferri sesquioxidum, ferri rubigo, rubigo, ferri peroxidum, ferri oxidum rubrum, peroxide of iron, red oxide of iron, iron rust, sesquioxide of iron, crocus ferri, crocus martis, ferrugo, polishing crocus, jewelers' rouge, venetian red, stone red, purple oxide, scarlet red.

A miscellaneous section contains eighty additional synonyms covering compounds not included in other sections. An excellent alphabetically-arranged cross-index enables one to identify quickly names which do not indicate the true chemical nature of the compound. The value of the book for reference work is increased by the inclusion of tables giving atomic weights, dates of discovery of the elements, occurrence of the metals in nature, temperature interconversions, comparison of specific gravity and degrees Twaddell and Baumé, weights and measures and conversion factors.

A few errors will be noted, such as listing barytes as a synonym of barium oxide, but these will undoubtedly be corrected at the first opportunity. As a time-saver, the book deserves the attention of every chemist in contact with the field of industrial chemistry.

ALAN G. WIKOFF.

Personal

Dr. HENRY ARNSTEIN, formerly technical director of the Cereal Products Refining Co. of San Francisco, has recently opened offices at 573 Twenty-second Ave., San Francisco. Dr. Arnstein has specialized in the manufacture of compressed yeast, maltose, alcohol, fats, vegetable oils and other food products and will enter consulting practice along these lines.

E. M. BISSONETTE, formerly with E. I. du Pont de Nemours & Co., Deepwater, N. J., is now with the Atlantic Refining Co., Pittsburgh, Pa.

F. W. BROWN recently resigned his position as sulphite superintendent of the Cascade Mill, Berlin, N. H., to accept the position of general manager of the bleached sulphite pulp plant of the Fraser Cos., Ltd., Edmundston, N. B.

GEORGE N. FISHER, formerly associated with the Certain-teed Products Corp., Niagara Falls, is now connected with the General Chemical Co., East St. Louis, Ill., as chemist.

F. C. FREEMAN, chief engineer for the Providence Gas Co., Providence, R. I., recently gave an illustrated lecture before the Providence Engineering Society on the manufacture of gas.

JOHN S. HARRIS, formerly of Klondike, Ariz., is now employed in the chemical department of the Empire Gas & Fuel Co., El Dorado, Kan.

E. J. HORWOOD, works manager for the Broken Hill Proprietary at Broken Hill, has been transferred to the Melbourne office of the company.

Dr. EDWARD H. HUME, head of the Yale University movement in China, addressed the Chicago Foreign Trade Club last week on the organization of the China Society of America.

HENRY N. LYONS, formerly with the Hercules Power Co., is now chief chemist with the Columbia Chemical Co., Barberton, Ohio.

Prof. ELIHU THOMSON, Swampscott, Mass., chief consulting engineer, General Electric Co., Lynn, Mass., has been appointed acting head of the Massachusetts Institute of Technology until a successor is chosen for the place, which was made vacant by the death of Richard Maclaurin.

HENRY LANE WILSON, former Ambassador to Mexico, spoke before the Detroit Chamber of Commerce on March 23, on business conditions in Mexico.

H. W. YOUNG, research chemist for the gas department of the Midwest Refining Co., has returned after an extended tour of the East, collecting information to be used in equipping an experimental laboratory at Salt Creek, Wyo.

Obituary

JOHN JEPPSON, superintendent and one of the founders of the Norton Co., Worcester, Mass., died in the Plaza Hotel, Havana, Cuba, Friday night, March 26, after an illness of two weeks. Mr. Jeppson's sickness dated from an attack of acute indigestion, from which he recovered sufficiently to reassure his relatives as to his condition, and the news of his death, received by Charles L. Allen, treasurer and general manager of the Norton Co., in a dispatch from George N. Jeppson, Mr. Jeppson's son, came as a surprise and shock to his thousands of Worcester friends.

Mr. Jeppson was born on a farm near Hoganas, Sweden, July 1, 1844, the son of Godman and Bengta (Person) Jeppson, and was seventy-five years, eight months and twenty-five days old. His remarkable career in Worcester began April 29, 1869, four days after he landed in New York, a poor Swedish immigrant.

Current Market Reports

The Non-Ferrous Metal Market

New York, April 5, 1920.—The copper market is still steady. March exports totaled 13,100 tons. For May delivery the price is 19.25c. There has been no movement in the price of nickel for a number of weeks, but silver has been fluctuating and is now $1.26½, against $1.23½ last week. Lead and zinc are steady both here and in East St. Louis. Tin has advanced a cent, as have scrap metals. Mercury is up $8 over last week.

	Cents per Lb.
Copper, electrolytic	19.00
Aluminum, 98 to 99 per cent	32@33
Antimony, wholesale lots	10.50@10.75

Zinc, scrap	4½@4½

The Iron and Steel Market

Pittsburgh, Pa., April 2, 1920.

The iron and steel market has become still quieter, and may almost be described by the term stagnant. The situation does not necessarily reflect any loss in the fundamental strength of the iron and steel position, though of course the extreme conservatism of banking interests at this time and the fear in some quarters that there will be an industrial depression in the near future might be contributing causes. The quietness in the iron and steel market is rather to be ascribed to the technical position of the market, through its having undertaken an advance which it could not sustain. The fancy prices recently paid for prompt deliveries of steel products, including not only sheets and plates but also several other descriptions of steel, are passing and indeed have already passed except for a very limited turnover. The higher prices being charged by large independents over Steel Corporation prices also have to go, though the complete elimination of these premiums may not be until quite a while in the future. With the steel market in process of readjustment buyers are naturally indisposed to take hold.

CAUSES OF STEEL MARKET DULLNESS

In the foregoing reference to the dullness in the steel market reference was made to two causes as if they were totally separate and distinct, but that, perhaps, is not the case. Reference was made to the general industrial and financial situation, on the one hand, and to the technical position of the steel market itself on the other. In a sense, however, the latter is a replica on a small scale of the former. The financiers and others who hold that there must be a readjustment in values and credits, and that there may be a mild industrial depression as a process of readjustment, maintain that prices are too high, that there is such inflation that sound business on a large scale cannot be conducted. If that is the general or average situation in business, the steel situation is the same thing in its narrower sphere. Steel prices started to advance above the Industrial Board price schedule of March, 1919, except that the United States Steel Corporation elected to continue selling at those prices. Many independent steel producers predicted a "runaway market" in steel, and the runaway actually started. Perhaps the proximate cause of the arrest of the runaway market was a production larger than had been expected by those who, actuated by their fears of a steel famine, paid fancy prices for prompt deliveries to eke out their contract deliveries, but a runaway would have been prevented from going far, even with smaller production, by a large amount of latent demand being held back from actual expression. Neither the railroads nor investment buyers generally would invest in steel at prices obviously affording the producers an inordinate profit after paying very high wages and buying supplies at extremely high levels.

Thus the steel market requires a readjustment because it had started out on the road of inflation, but what the bankers assert is that the whole country is on an inflated basis and all commercial operations will have to be adjusted to a more moderate, and therefore safer, level. Accordingly, whether one attributes the present dullness in the steel market to there having begun a readjustment in business generally, or to there having begun a readjustment in steel prices, in either case the matter rests upon the same economic principle, that successful business cannot long be conducted on an inflated basis. It is pertinent to observe another connection, that the Steel Corporation has steadfastly refused to participate in the advance in steel prices, adhering to the Industrial Board schedule, and that the policies of the Steel Corporation are, in the last analysis, directed largely by financial interests.

RAILROAD BUYING

When inquiries for freight cars began to appear in volume at the beginning of March, when the railroad lines were returned to their owners, it was predicted that car buying on this movement would involve not less than 50,000 cars and might run to 100,000 cars. Now it appears doubtful

whether even the lower figure will be attained. The chief difficulty mentioned is that of financing, the railroads offering payment largely in notes, and in some cases proposing to pay only 25 per cent in cash. Undoubtedly another difficulty is that the railroads feel that prices are too high, since the car companies could secure but little steel for early deliveries at the Steel Corporation prices. There is scarcely any railroad inquiry for bridges and structural material generally.

Steel Prices and Sales

The large independent steel companies have not formally opened their order books for third quarter deliveries of such materials as bars, shapes and plates, but may do so shortly. It appears that their customers prefer that the opening should occur later, preferring not to be forced to commit themselves just at this time. Some business has been done, however. Mills have been stating that they do not expect to set their third quarter prices at above 3c. for bars, 3.10c. for shapes and 3.25c. for plates. The Steel Corporation continues to sell in most of its lines, but transactions have been lighter of late, and the corporation's unfilled tonnage statement may show a decrease for March, after heavy increases in preceding months.

Open Coke Market

In one branch of the general market there have been spectacular performances in the past week, the Connellsville coke market. Predictions have been made that when Government price limits, $6 for furnace coke and $7 for foundry, should be removed the market would advance to $9 or thereabout for furnace coke. The actual removal of the restrictions became actually effective at the end of March, but before that time transactions began, for shipment and invoicing April 1 and later. The initial sales were at $9, a few prompt lots going at this figure as well as a fair sized tonnage for the month of April and a small monthly tonnage for the remainder of the year. Then the market began advancing sharply from this level, by 50c or $1 a day, and in the past two or three days it has stood at $11 to $12 for furnace and at $13 to $14 for foundry coke per net ton at ovens. Coke operators seemed to feel that the price should be the same whatever the delivery, whether April, second quarter or balance of year, but at such high levels furnaces became reluctant to commit themselves for more than the month of April.

Nearly all the April business has now been done. The turnover has been chiefly in coke that was released by the expiration of first quarter contracts or understandings between producer and consumer, good for the period of Government control, that coke would be furnished and invoiced at the Government price. As contract deliveries had been somewhat under requirements, the termination of these contracts and understandings operated to create larger uncovered consumption than unsold production.

The advance in coke seems to have had a stiffening effect upon the attitude of blast furnaces in the matter of pig-iron prices, which are now quite firmly held. Pig-iron consumers, however, are not in the market to any extent.

Chemical and Allied Industrial Markets

New York, April 5, 1920.

There has been no change in the general condition of the heavy chemical market during the past week. Spot offerings are practically unobtainable and there is very little material to be had on future delivery. Prices have strengthened and where there has been no actual rise quotations are firmer at the previous levels. The shipment of supplies from the West is still being hampered by transportation difficulties.

General Chemicals

Barium chloride still remains in a nominal position. Spot material is practically unobtainable and producers are working to fill back contracts. The quotation of $140@$150 per ton still holds. *Potassium bichromate* is firmer at 36@37c. per lb. than at the previous quotation of 32@33c. There is very little material available and producers are reported well sold up for the next few months. *Chloroform* came up slightly, being listed at 29@30c., against 28c. of last week. The usual business is being done, with nothing of particular interest in view. *Alcohol*, wood, has jumped still higher, quotations ranging from $2.35@$3.50 per gal. according to the proof. *Caustic potash* is practically unobtainable, the present listing being 28@29c. per lb. Supplies on *sal soda* are still tighter, which has affected the price, it being listed at $22@$26 per ton, against $21@$22 of last week.

Coal-Tar Products

The already reported shortage in all branches in this market still holds. Crude material is especially short and this is holding up production to such an extent that the spot market is at a standstill. There is no scarcity of buyers who are anxious to obtain material at most any price. *Aniline oil* has tightened up slightly, being listed at 34@45c. per lb. *Dimethylaniline* is still off the market, although some small quantities have changed hands at $1.50 per lb.

Naval Stores

This market remains in the same position in which it was last week. Rosins are still scarce, while turpentine is not to be had in the New York market at any price, but $2.36 per gal. is the nominal quotation of the week.

Crude Rubber

This market has been at a standstill during the past few weeks. There are several reasons for this condition, the principal one being fluctuating foreign exchange, as manufacturers will not go in the market on a speculation basis. Other contributing causes are the present condition of the spot market in relation to future delivery and the difficulty on the part of the tire manufacturers to obtain fabric, which has limited the buying of rubber. During the war the Government cut importations of crude rubber in half, which allowed large quantities to accumulate, and this material is now being offered on the spot market, causing future offerings to be turned down by the buyer for the more favorable spot price. The extreme tire fabric shortage is also a large factor in the present depression, as manufacturers will not buy the rubber when their output is being limited by the small quantity of fabric being received. It is the opinion of those doing business in this market that a firm rising exchange will go a long way toward putting this market back in its former position.

Ferro-Alloys

Ferromanganese continues upward with no relief in sight. Car shortage and labor trouble at the docks, combined with the extreme shortage of supplies are accountable for the increasing market price on this item. Quotations on English material for prompt shipment are $200 per ton and for last half $175@$200 is being asked, with no actual offers to be found even at these prices. Domestic is listed $235@$240 prompt delivery and $200@$220 for last half.

Spiegeleisen remains firm, with business being transacted at prices ranging from $60@$65 per ton.

Miscellaneous

The barytes market is at a standstill, as there is very little material to be obtained. Demand so far exceeds output that producers have warned their selling representatives not to take any more contracts without first consulting the works. No price is being quoted on contract goods, all goods being sold at current price at time of delivery. The spot market is also practically bare of this material and as high as $40 per ton is being asked for white floated, while the off-color grade is listed at $25@$30 per ton.

Tungsten is firmer under the influence of pending legisiation. Although there has not been any larger business than usual, *wolframite* is firmer at $6.50@$7.50 per unit than it was last week.

Fullers earth remains firm at $25@$30 for domestic and $35@$40 for foreign, with very little material available at these prices.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

Epsom salt (see magnesium sulphate)		..–.....	..–.....
Formaldehyde, 40 per cent (nominal)	lb.	.38 – .40	.60 – .80
Glauber's salt (see sodium sulphate)		..–.....	..–.....
Glycerine	lb.	..–.....	.24½– .26
Iodine, resublimed	lb.	..–.....	4.10 – 4.30
Iron oxide, red	lb.	..–.....	.03 – .20
Iron sulphate (copperas)	cwt.	1.20 –.....	1.50 – 2.00
Lead acetate, normal	lb.	.12 – .13	.14 – .23
Lead arsenate (paste)	lb.	..–.....	.13 – .17
Lead nitrate, crystals	lb.	..–.....	.70 – .90
Litharge	lb.	.14 – .15	.15½– .16
Lithium carbonate	lb.	..–.....	1.50 –.....
Magnesium carbonate, technical	lb.	..–.....	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	3.40 – 3.55	3.60 – 3.75
Magnesium sulphate, commercial	100 lb.	3.00 – 3.10	3.10 – 3.25
Nickel salt, double	lb.	.14 –.....	.15 –.....
Nickel salt, single	lb.	.16 – .17	.17½–.....
Phosgene (see carbonyl chloride)		..–.....	..–.....
Phosphorus, red	lb.	..–.....	.60 – .65
Phosphorus, yellow	lb.	..–.....	.35 – .37
Potassium bichromate	lb.	.36 – .37	.38 – .40
Potassium bitartrate (cream of Tartar)	lb.	..–.....	.56 – .60
Potassium bromide, granular	lb.	..–.....	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60 –.....	.65 – .70
Potassium carbonate, crude	lb.	.26 – .27	.28 – .30
Potassium chlorate, crystals	lb.	.15 – .20	.21 –.....
Potassium hydroxide (caustic potash)	lb.	.28 – .29	.30 – .35
Potassium iodide	lb.	..–.....	3.35 – 3.60
Potassium nitrate	lb.	.19 –.....	.21 –.....
Potassium permanganate	lb.	..–.....	$0.65 – $0.95
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1.20
Potassium prussiate, yellow	lb.	.34 – .36	.38 – .40
Potassium sulphate	ton	$225.00 –.....	..–.....
Rochelle salts (see sodium potas. tartrate)		..–.....	..–.....
Salammoniac (see ammonium chloride)		..–.....	..–.....
Sal soda (see sodium carbonate)		..–.....	..–.....
Salt cake	ton	22.00 –26.00	..–.....
Silver cyanide (nominal)	oz.	..–.....	1.25 –.....
Silver nitrate (nominal)	oz.	..–.....	.77 – 82¾
Soda ash, light	100 lb.	..–.....	3.50 – 3.60
Soda ash, dense	100 lb.	2.70 – 2.75	3.55 – 3.65
Sodium acetate	lb.	.06¾– .07	.07 – .08
Sodium bicarbonate	100 lb.	2.40 –.....	2.75 – 3.00
Sodium bichromate	lb.	.33 – .34	.35 – .36
Sodium bisulphate (nitre cake)	ton	7.00 – 7.50	8.00 – 10.00
Sodium bisulphite Powered	lb.	.05½– .06½	.07 – .07½
Sodium borate (borax)	lb.	.08½– .08¾	.09 – .09½
Sodium carbonate (sal soda)	100 lb.	1.60 – 1.80	1.80 – 2.00
Sodium chlorate	lb.	.10 –.....	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.14 –.....	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	..–.....	6.75 – 7.00
Sodium hyposulphite	lb.	..–.....	.03¾ .04
Sodium molybdate	lb.	2.50 –.....	3.25 –.....
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	..–.....	.25 – .30
Sodium peroxide, powdered	lb.	..–.....	.30 – .32
Sodium phosphate, dibasic	lb.	.03¾– .04½	.04½– .05
Sodium potassium tartrate (Rochelle salts)	lb.	.39 – .40	.40 – .41
Sodium prussiate, yellow	lb.	.23 – .2z	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01½– .02	.02 – .0¾
Sodium silicate, solution (60 deg.)	lb.	.02¼– .03	.04 – .05
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.15 – 1.40	1.60 – 2.00
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	..–.....	.05 – .06
Sodium sulphite, crystals	lb.	.03½–.....	.04 – .06
Strontium nitrate, crystals	lb.	.25 –.....	.28 –.....
Sulphur chloride	lb.	.05¾–.....	.06 –.....
Sulphur, crude	ton	22.00 –.....	..–.....
Sulphur dioxide, liquid, cylinders	lb.	.09 –.....	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –.....	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –.....	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½–.....	.46 – .50
Tin oxide	lb.	.50 – .60	.65 –.....
Zinc carbonate, precipitate	lb.	..–.....	.19 – .20
Zinc chloride, gran.	lb.	.13 –.....	.13½– .15
Zinc cyanide	lb.	.49 –.....	.50 – .60
Zinc dust	lb.	.11¾– .12½	.13 – .15
Zinc oxide, U. S. P.	lb.	..–.....	.19 – .21
Zinc sulphate	lb.	.03½– .03¾	.04 – .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.40 —	.50
Aniline oil, drums extra	lb.	.34 —	.45
Aniline salts	lb.	.42 —	.48
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.25 —	1.35
Benzidine, sulphate	lb.	1.00 —	1.15
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.31
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.65
Beta naphthol, sublimed	lb.	.70 —	.90
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 —	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85 —	1.00
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.70
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline (nominal)	lb.	.95 —	1.50
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine (nominal)	lb.	.55 —	.65
H-acid (nominal)	lb.	1.75 —	1.90
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.08 —	.09
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.70 —	.80
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.75 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.12 —	.18
Paranitraniline	lb.	1.00 —	1.35
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.15 —	3.00
Paratoluidine	lb.	1.75 —	2.50
Phthalic anhydride	lb.	.65 —	.75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	4.25 —	4.50
Resorcin, pure	lb.	6.25 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.45 —	.50
Salicylic acid, U. S. P.	lb.	.55 —	.60
Salol	lb.	.90 —	1.00

Solvent naphtha, water-white, in drums, 100 gal..	gal.	$0.25	—	$0.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.25	—	.30
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.....
Xylol, commercial, in drums, 100 gal	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dar\	lb.	$0.39	—	$0.40
Beeswax, refined, light	lb.	.40	—	.41
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1, (nominal)	lb.	.80	—	.88
Carnauba, No. 2, regular (nominal)	lb.	.60	—	.70
Carnauba, No. 3, North Country (nominal)...†	lb.	.43	—	.45
Japan	lb.	.17	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.....	—	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.11
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	—	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.11	—	.11¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.12	—	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.12½	—	.14
Stearic acid, single pressed	lb.	.26	—	.27
Stearic acid, double pressed	lb.	.32	—	.29
Stearic acid, triple pressed	lb.	.32	—	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist.	gal.	...
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.47
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.060	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.95	—	$19.50
Rosin E-I	280 lb.	19.75	—	20.00
Rosin K-N	280 lb.	20.25	—	20.50
Rosin W. G.-W. W.	280 lb.	22.00	—	22.50
Wood rosin, bbl.	280 lb.	15.50	—	17.50
Spirits of turpentine	gal.	.	—	2.35
Wood turpentine, steam dist.	gal.	.	—	2.25
Wood turpentine, dest. dist.	gal.	.	—	2.10
Fine tar pitch, bbl.	200 lb.	8.40	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	15.00
Retort tar, bbl.	500 lb.	15.00	—	15.50
Rosin oil, first run	gal.	.92	—	.95
Rosin oil, second run	gal.	.94	—	.97
Rosin oil, third run	gal.	1.12	—	1.15
Rosin oil, fourth run	gal.	1.17	—	1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

ara—Upriver fine	lb.	$0.40½	—	$0.42
Upriver coarse	lb.	.30½	—	.32
Upriver caucho ball	lb.	.32½	—	.33
Plantation—First latex crepe	lb.	.47½	—	.48½
Ribbed smoked sheets	lb.	.47	—	.48
Brown crepe, thin, clean	lb.	.45	—	..
Amber crepe No. 1	lb.	.46	—	.47

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19	—	$0.20
Castor oil, AA, in bbls.	lb.	.20	—	.23
China wood oil, in bbls.	lb.	.24½	—	.25½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.19	—	.19½
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½	—	.23
Corn oil, crude, in bbls.	lb.	.17½	—	.19
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½	—	.18
Cottonseed oil, summer yellow	lb.	.19½	—	.20½
Cottonseed oil, winter yellow	lb.	.22	—	.24½
Linseed oil, raw, car lots	gal.	1.74	—	
Linseed oil, raw, tank cars	gal.	1.67	—	
Linseed oil, boiled, car lots	gal.	1.77	—	
Olive oil, commercial	gal	2.50	—	3.00
Palm, Lagos	lb.	.16	—	.16½
Palm, bright red	lb.	.15½	—	.17½
Palm, Niger	lb.	.15	—	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.20½	—	.22
Peanut oil, refined, in bbls.	lb.	.27	—	.28
Rapeseed oil, refined in bbls.	gal	1.70	—	1.78
Rapeseed oil, blown, in bbls.	gal.	1.80	—	1.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19	—	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.19¼	—	.20

FISH

Winter pressed Menhaden	gal.	$1.17	—	$1.18
Yellow bleached Menhaden	gal.	1.20	—	1.22
White bleached Menhaden	gal.	1.23	—	1.24
Blown Menhaden	gal.	1.30	—	1.35

† (See New York market letter)

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	.....	—	$40.00
Barytes, off color	ton	$20.00	—	25.00

Talc, imported	ton	60.00	—	70.00

*Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20	—	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21	—	.22
Ferro-manganese, 70-80% Mn.	gross ton	180.00	—	240.00
Spiegeleisen, 16-20% Mn.	gross ton	60.00	—	65.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.25	—	2.75
Ferro-silicon, 50%	gross ton	80.00	—	90.00
Ferro-silicon, 75%	gross ton	150.00	—	200.00
Ferro-silicon, 10-15%	gross ton	60.00	—	65.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	.90	—	1.10
Ferro-uranium, 35-50% of U	lb.	7.00	—	...
Ferro-vanadium, 30-40% per lb. of contained V....	lb.	6.50	—	7.50

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70	—	$0.85
Chrome ore, 48% and over	unit	1.00	—	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00	—	
*Coke, furnace, f.o.b. ovens	net ton	6.00	—	
Petroleum coke, refinery, Atlantic seaboard	net ton	.....	—	14.00
Fluor spar, gravel, f.o.b. mines	net ton	25.00	—	30.00
Manganese ore, 45% Mn and over	unit	75	—	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00	—	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	75	—	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00	—	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50	—	7.50
Uranium oxide, 96%	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	6.00	—	...
Pyrites, foreign, lump	unit	17	—	...
Pyrites, foreign, fine	unit	17	—	...
Pyrites, domestic, fine	unit	16	—	.17½
Ilmenite, 52% TiO_2	lb.	.02	—	...
Rutile, 95% TiO_2	lb.	.11	—	...
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75	—	3.00
Zircon, washed, iron free	lb.	.10	—	...
Monazite, per unit of ThO_2	unit	42.00	—	...

*Government prices.

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage, 25c. for 19 to 24 gage, for galvanized corrugated sheets, add 10c., all gages.

Construction and Operation

California

LOS ANGELES — King W. Vidor has awarded the contract for the construction of seven 1- and 2-story picture-producing buildings on Santa Monica Blvd., to the Milwaukee Bldg. Co., 316 Wright & Callender Bldg. Estimated cost, $100,000.

Connecticut

MIDDLETOWN—The Standard Oil Co., 26 B'way, New York City, plans to build an oil plant along the Connecticut River. Estimated cost, $100,000.

Illinois

CHICAGO—Shea, Smith & Co., 322 Federal St., manufacturing stationers, plan to build a 5-story steel and concrete factory at Congress St. and Ashland Blvd. Estimated cost, $600,000.

CHICAGO—The Vulcan Louisville Smelting Co., 208 South La Salle St., plans to rebuild a part of the North Chicago plant which was recently destroyed by fire. Estimated cost, $400,000.

Indiana

EVANSVILLE — Clifford Shopbell, 707 Furniture Bldg., will receive bids for the construction of a 2-story, 80 x 150-ft. factory for the Liquid Carbonic Co., Heidelback Ave. and Indiana St. Estimated cost, $30,000. Noted March 3.

Kansas

PROTECTION—The city is receiving bids for the construction of a disposal plant. Filter equipment will be installed in same. Estimated cost, $50,000. W. B. Rollins & Co., 209 Railway Exch. Bldg., Kansas City, Mo., engr.

Louisiana

NEW IBERIA—The United Fiber & Products Co. has purchased the mill of the Sugar Cane By-Products Co. and will install new machinery in same. The mill will have a daily capacity of 15 tons newsprint paper. W. T. Larkin, 1520 Fidelity Bldg., Baltimore, Md., pres. F. Logan, 467 C St., N. W., Washington, D. C., engr.

Maryland

BALTIMORE—The Presto-Lite Co., Inc., 30 East 42nd St., New York City, is having plans prepared for the construction of eight 1-story, 25 x 100-ft. acetylene plants. Estimated cost, $75,000.

LANSDOWNE—The Natl. Steel Rolling Co, 203 Keyser Bldg., Baltimore, has purchased the plant of the Schuylkill Haven Rolling Mill Co., Schuylkill Haven, Pa., and plans to build a subsidiary plant near here. The plant will be an oil and electric steel reclaiming bar mill and will have an annual capacity of 9,000 tons. Estimated cost, $100,000.

Massachusetts

FITCHBURG—Croker, Burbank & Co., 549 Westminister St., has awarded the contract for the construction of a 2-story, 46x300-ft. machine shop, 1-story, 54x100-ft. spinning shop and a 2-story, 130x130-ft. header shop, to E. J. Cross Co., 82 Foster St., Worcester. Estimated cost $400,000.

Michigan

NORTHVILLE — The Detroit Bd. of Health, 233 St. Antoine St., Detroit, received bids for the construction of a 2-story, 28x26-ft. laboratory, in connection with the group of buildings to be constructed at the proposed Detroit Municipal Tuberculosis Sanitarium, from John Finn & Co., 234 East Fort St., Detroit, $29,375; George A. Fuller Co., 540 Penobscot Bldg., Detroit, $30,700. Noted Feb. 26.

Missouri

ST. LOUIS—The Amer. Bakers' Machine Co., 2121 North 9th St., plans to build a factory and office building on Kingshighway and McRee Ave. Estimated cost, $110,000.

ST. LOUIS—The Skinner Bros. Mfg. Co., 10th and Tyler Sts., builders of industrial heaters and blow piping systems, is building a factory at Lunt and Vandeventer Ave. Estimated cost, $250,000.

New Jersey

NEWARK—The Seaboard Chemical Co., Blanchard St., has awarded the contract for the construction of a wood alcohol plant, to Edward M. Waldron, Inc., 665 Broad St. Estimated cost, $40,000. The company will be in the market for chemicals for the manufacture of wood alcohol.

PLEASANTVILLE—The Common Council, City Hall, will receive bids until April 19 for the construction of a sewage screening plant, etc.

TRENTON—The Kelso Mfg. Co., asbestos manufacturer, 58 Market St., plans to construct a factory addition on Market St.

New York

BROOKLYN—Fred A. Phelps, archt., Union Bldg., Newark, N. J., will receive bids until April 24 for the construction of a 4-story, 55x175-ft. paint factory at Hamilton and Smith Sts., for Devoe Reynolds, 460 Smith St., and will be in the market for chemicals for the manufacture of paint. Noted March 17.

BUFFALO—The Hewitt Rubber Co., Kensington Ave., plans to build a 2-story brick addition to present plant. Estimated cost, $25,000.

New Mexico

LORDSBURG—The Great Eagle Mine is in the market for crushing machinery, etc. J. W. Cauthen, supt.

Ohio

ASHLAND—The city has awarded the contract for the furnishing and installing of filter equipment for the proposed 1-story filtration plant, to the Amer. Water Softener Co., 1011 Chestnut St., Philadelphia, Pa., at $34,000. Noted March 31.

CINCINNATI—The Presto-Lite Co., Inc., 30 East 42nd St., New York City, is having plans prepared for the construction of a few 1-story, 25 x 100-ft. acetylene plants. Estimated cost, $75,000.

CLEVELAND—The Cleveland Steel Co., Rockefeller Bld., plans to build a 1-story steel plant on West 117th St. and the Big Four R.R. Estimated cost, $350,000. C. J. Jones, mgr. A. S. McKee Co., Rockefeller Bldg., engr.

ELYRIA — H. A. Beck, Dir. of Pub. Servc., City Hall, will receive bids until April 26 for the furnishing and installing filter plant equipment.

DOVER—The Dover Mfg. Co., c/o Poe Eng. Co., archt. and engr., Rockefeller Bldg., Cleveland, O., plans to build a 3-story, 80x200-ft. factory. Estimated cost, $100,000.

Pennsylvania

PHILADELPHIA—The Presto-Lite Co., Inc., 30 East 42nd St., New York City, is having plans prepared for the construction of a few 1-story, 25x100 ft. acetylene plants. Estimated cost, $80,000.

South Dakota

MOBRIDGE—The city had plans prepared for the improvement of the waterworks system, taking water supply from the Missouri River, with filtration. Estimated cost, $175,000.

Texas

TEMPLE—The Southland Oil Co. is rebuilding its cotton seed-crushing plant. E. A. Dill, engr. Estimated cost, $60,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive at St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHAMBER OF COMMERCE OF THE U. S. announces that its eighth annual meeting will be held at Atlantic City, April 27 to 29, the subject of which will be "Increased Production."

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theater: "Romance of Leather Making," Tuesday, April 13, at 4 p.m., E. A. Brand (*Lantern*); "Water Supply and Drainage in War Cantonments." Wednesday, April 21, at 4 p.m., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 p.m., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 p.m., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 p.m., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE ELECTRIC FURNACE ASSOCIATION will hold a meeting in Boston, April 8 to 10, together with the American Institute of Electrical Engineers and the American Electrochemical Society. The subject is "Electrically Produced Alloys and Power for Electrochemical Purposes." Headquarters will be at the Copley-Plaza Hotel.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E., will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE INTERNATIONAL MINING CONVENTION will be held in Seattle April 7 to 10.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MINE INSPECTORS' INSTITUTE OF AMERICA will hold a meeting at Cleveland, Ohio, July 13.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5 which will be held in Glace Bay.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept, 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE NATIONAL SAFETY COUNCIL, Engineering Section, will hold its spring conference in the Engineering Societies Building, New York City, on April 27.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Patent Royalties For Government Employees

THE report that Government employees are to receive a portion of royalties which may accrue from patents on inventions made or developed within Government time is worthy of note. Under the bill, which, as reported in our last issue, has passed the Senate, the Federal Trade Commission is to administer the patents and the President is to fix the percentage of royalties allowed to employed inventors. We take it that examiners in the Patent Office are not to participate in this privilege for the reason that a type of man that has thus far been pretty well avoided would be encouraged to enter that occupation. The temptation to file claims that would establish profitable interferences would invite the wrong men to come in as examiners.

Teaching and Government service appeal to some men of the very first rank. It is known beforehand that these occupations do not lead to wealth, as do occasional opportunities in industry. On the other hand, except in institutions of learning that suffer from the control of politics, a kind of academic freedom is provided, the annoynace of hasty and slipshod performances to beat a rival concern are avoided, the pay is regular, the domicile of a person so employed is likely to be in a pleasant place and there is a dignity attached to either calling that is at once agreeable and distinguished.

The Bureaus of Mines and of Chemistry are places where the value of such privileges may speedily develop. Many patents have emanated from these bureaus and have been assigned to the Government for the public welfare.

Whether or not the inventor should have any participation or share in the proceeds of his work done on Government time is a question of expediency rather than of ethics. The purpose of corporate research is for the benefit of the corporation, and this holds true for the people as well as for stockholders. But in industry a man is supposed to be able to look after himself, whereas in Government service he has no voice in making rules or contracts. He can accept or decline, but he cannot negotiate. We should like to see Dr. COTTRELL, for instance, made rich in spite of himself; for anyone who contributes as much as he has to human welfare and industrial progress is entitled to it. In England he would have been Sir FREDERICK long ago, while in Germany in the old days he would have been a real, simon-pure, genuine privy councillor "mit dem Prefix Excellenz" and probably ennobled into the bargain. It is men of this type, however, who are not even interested in the emoluments of office. They have a sane view of life, welcoming the luxuries of civilization but with no desire whatever for plutocratic luxuries. They do not want to keep their eyes at the point of strain to catch opportunities on the fly or to scrap with contemporaries for control or advantage. And the reward proposed is unlikely to be opulent. It is hardly enough of a bait to lure into the Government service shifty persons whose desire for profit is a constant hazard to character and who prefer dollars to a clear conscience.

Another point in its favor is that it will constitute an ever-present premium on the application of pure science to the use and benefit of society. Incentives of this sort have great potential value.

There may be serious objections to the proposal, but at present writing we are impressed with its advantages.

The Soviets At Work

UNDER the title, "The Soviets at Work," LENIN has recently made a statement that should be brought to the attention of every American. It deserves quotation in full:

"The bolshevists have destroyed capitalism, nationalized industry and formed workers' soviets. But Russia is still far from communism and a socialistic soviet republic.

"What the bolshevists have done so far was the easiest part. It was the destructive part. It required only force and decrees. The hardest part is still before them. Bolshevism will fail unless it can rebuild Russian industries and get maximum production.

"This cannot be accomplished under the original plan of bolshevism. The workers' soviets don't know how to run the factories and keep order. And the workers aren't yet willing to work for the same rate of pay for different kinds of work. The machine worker still wants more than the man with a pick; and the brain worker still wants more than the machine worker. Russia will not have communism until human nature is changed and each man is willing to work for the good of all instead of for personal gain.

"It will take years to change human nature by education and to teach workers to run factories by soviet methods. But in the meantime industry must be recognized and maximum output by both factory and the individual worker maintained.

"The only course before the bolshevist leaders is to take a step backward from the soviet state—to return to the old order. They must call in bourgeois experts at large salaries to run the factories. They must adopt the factory methods of capitalistic America.

"And the bolshevist leaders must go back still further. They must place the workers under iron discipline. They must make the hundreds and thousands of workers in each factory subject to the will of one man—the

bourgeois manager. The workers must be compelled to work their hardest."

Thinking men by the thousands have said that with an ideal human family socialism would be a most desirable system. LENIN, the proponent of Russian communism, from the depths of his terrible experience, approves those views.

If we could get a knowledge of what is transpiring in Russia into the minds of our loose-thinking elements it would lead them to improve what we have rather than advocate the Russian system—and to court the inevitable Russian chaos.

The Rule and Its Exceptions On the Properties of Lubricants

IF THERE is any actual rule for grading lubricants, a statement of it would embody the following five general principles: Purity, freedom from acid or corrosives, maximum adhesion to the surfaces to be lubricated, minimum internal cohesion or resistance to shear and stability under conditions of use. About a dozen laboratory tests have been devised to determine whether or not a given lubricant conforms to all of these specified properties. The application of this series of tests, however, has been to give a convenient means for comparing the qualities of an unknown lubricant with those that are found in lubricants that have proved most satisfactory after many years of actual use. Exceptions to indications of these tests have been found, so a knowledge of when the rule does not apply is of paramount importance to the rule itself.

The "germ" process recently introduced in England apparently is a good case for discussion. In this process mineral oils are compounded with from one to two per cent of rape-oil fatty acids, and the same reduction in the coefficient of friction is obtained as with twenty per cent of the neutral glycerides. From time immemorial, neutral rape-oil has been specified, so as to meet an acid test, which was actually designed to prevent the sale of refined lubricants from which the last traces of sulphuric acid had not been removed.

It is possible that the term acid will gradually come to have the qualification of "mineral" applied to it. At the same time, it may be expected that instead of removing all the unsaturated hydrocarbons, the lubricant refiner of the future may be a sort of synthetic chemist and make his anti-friction fatty acids right in the oil by adding carboxyl groups on to the open double bonds instead of sulphonating and removing them.

How They Do It Out in Kansas

GOVERNOR HENRY ALLEN recently addressed the Chicago Chamber of Commerce on the operation of the new industrial law in his state for preventing strikes. A special session of the Legislature was called during the coal strike last winter and a law was passed which would make it impossible for the recurrence of such wasteful events in the industries. The court which has been established is a court neither of arbitration nor of conciliation, but a court of justice operating as the chief representative of the State Government.

The law has not been exactly popular with a certain section of the labor element that has seemed inclined lately to run amuck.

However, a recent example of how the law functions is best described in Mr. Allen's own words:

> The other day there came to me a man representing the Maintenance of Way Railroad Craft in Kansas. He had just received from his national officer at Detroit orders to call out on strike the men who work in the maintenance-of-way crafts of the railroad organizations. He had also received orders to pass the word along as rapidly as he could. Now this man knew about this law, and he came to me and handed me the telegram, and said, "Governor, what will happen to me if I pass the word along to my locals?" I said, "Sit down, and we will read this law for a minute."
>
> I ran my finger underneath the lines that provided the penalty, and I read that to him, and in a moment I heard him swallowing his epiglottis, and he said, "Why, you could fine me $1,000, couldn't you, because I am the head of this organization?" "Well," I said, "read these other lines." "Why," he said, "you could put me in the penitentiary for a year," and I said, "Yes. Since you have come to me and have taken the trouble to consult me about the law on the matter, I am inclined to think that I would give you both barrels."

Looking backward over several decades, we may recall that other things have originated in Kansas which later became successful national measures dealing with difficult situations.

May the nation continue to look westward for future inspiration?

The Muscle Shoals Plant Should Be Operated

EDITORIALLY we have already commented upon the proposal of the War Department to operate the Muscle Shoals nitrogen fixation plants and expressed the opinion that the proposals of the War Department to this effect were sound. The criticism of this plan made before the Senate Agricultural Committee last week, as reported elsewhere in this issue, has not changed our general conclusions, although the additional light which has been thrown upon this subject is very interesting indeed.

It seems that there are several important reasons why the Government cyanamide plant at Muscle Shoals should be operated.

First, we believe that the nitrogen-using industries of this country can absorb the output of ammonia, nitrates and other forms of nitrogen available without being affected materially by the output of this small plant. Its output will form only a few percent of the total available nitrogen needed in this country and this certainly is not sufficient to materially affect our nitrogen markets.

Second, we believe that the War Department can best keep in touch with nitrogen fixation conditions and can gain most valuable experience only if it retains active interest and participation in some phase of these industries. The continuance of the Muscle Shoals plant and the investigations which will accompany this plant operation should give the Ordnance Department extremely valuable experience which will be much needed in case this country should ever again be confronted with serious war conditions.

Third, we believe that the losses to the Government will be less if it continues to operate this plant (at least for the near future) than if the plant is allowed to lie idle or is sold to any private interest either immediately or in the near future.

Fourth, we believe that the American chemist has sufficiently developed the art of converting cyanamide

into ammonia, and by oxidation of this ammonia into nitrates, to justify considering the product of this plant as available either as a substitute for ammonium sulphate or as a substitute for Chilean nitrate. Ammonia and nitrates are somewhat interchangeable, for the present state of knowledge makes it readily possible to convert ammonia into nitrate at costs that are not by any means prohibitive—especially in periods of emergency. The conclusion that there is a surplus ammonia capacity in this country which can do nothing to eliminate the need for importing Chilean nitrate is therefore not correct.

No policy, such as may have been proposed by some Government representatives, should be adopted permitting some Bureau to enter into the fertilizer market in competition with the American Cyanamid Company or other similar interests. General Government operation of manufacturing plants is not desirable where industries stand ready to care for the supply of needed materials. Any evident injustice against corporate interests that have co-operated with the Government in the development of their plants or processes during the war period should be certainly vigorously opposed. If the patents and the contracts under which the Muscle Shoals plant was constructed and operated are as satisfactory as the private interests seem to believe them to be, we see no reason why an observance of these contracts and patent rights will not amply protect individuals against Government interference except that in the field of ammonia resources or possibly in the field of nitrate supply the product of the Government's effort may for a brief period seem to be competing tonnage. However, this competition will not be either serious or long continued and we reiterate, therefore, that we still believe reasons entirely different from the commercial aspects of the matter fully justify continuance of the plan proposed for operation of this plant.

The Tonnage Output Of the Steel Industry

IT IS a good motto, and a useful one, that "obstacles were made to be overcome." The steel industry is now showing, in its tonnage outputs, the results of having learned fresh lessons during the war in overcoming obstacles. It is not long ago that what appeared to be a gloomy view of the future tonnage output of the industry was being taken by some classes of officials in steel companies, particularly in sales departments, but the actual tonnage outputs being made indicate that the steel industry is already on a fair road toward functioning better than ever, and producing a total output larger than it had been supposed capable of producing even under favorable physical conditions.

During the war there was much evidence of the steel industry straining itself to the utmost to produce a maximum of steel, and in the forms requisite for prosecuting the war, but when statistics were gathered of actual outputs they were, in the main, quite disappointing. Evidently there were few plants that produced as much steel in either 1917 or 1918 as in 1916, unless they had added to their facilities, and this made it appear that the steel producers, however desirous they were of bringing about the best results possible, were failing in their effort. There were very great difficulties, however, production being impeded at almost every step, not only by the transportation difficulties, which were notorious, but by many other things. There is good reason to infer that if the managers, superintendents and others directly responsible for mill and furnace operations had exerted themselves no more during American participation in the war than they had in 1916 the tonnage outputs of 1917 and 1918 would have been much less than they were. It is not alone the total tonnages of the two years that are to be considered, but also the difficulties under which those tonnages were produced.

A difficulty or obstacle overcome makes it possible to accomplish still more the next time there is a test. This is no new experience for the American steel trade. The market has been subject to its ups and downs. The trade had "either a chill or a fever," as was remarked by the late JAMES M. SWANK nearly a third of a century ago, while later ANDREW CARNEGIE observed that the steel industry was "either a prince or a pauper." There have been alternations whereby in one period, perhaps for a few months or perhaps for a couple of years, mills and furnaces would be strained to produce maximum tonnage, while in an intervening period there would be an insufficiency of orders, with specifications inconvenient for efficient rolling at that. At the average plant it has been the experience that almost month after month during a period of activity new tonnage records would be made, while from one period of activity to the next a great deal would be gained. It should not be surprising, therefore, if after the strenuous times of the war, forcing the devising of new expedients, the steel mills should be found now able to function better than they did in 1916. The actual capacity, measured in terms of trains of rolls and number of open-hearth furnaces of given dimensions, has of course greatly increased. In terms of steel ingots the increase in nominal capacity from the beginning of 1915 to the present time has been estimated at fully 40 per cent, only a relatively small portion of this capacity having been effective in 1916, the year that bears the palm of the past four for tonnage output in steel ingots proportionate to rated capacity.

Aggregate tonnages are not yet record breaking by any means, for there are transportation difficulties in the way, but individual cases show record-breaking outputs. A conspicuous case is that of the National Tube Company, furnishing no insignificant illustration since the company produces about 4 per cent of all the finished steel of the country. This company had a larger production in March, by a very comfortable margin, than in any previous month in its entire history.

The steel industry has been a leader in many respects, illustrating what can be accomplished by courage in adopting heavy machinery and trying new devices and methods. With the world at large, including the United States, suffering economically from inefficiency and what amounts to laziness, the steel industry of the United States will help the world if it sets an example now of producing steel at a greater rate than it had been assumed capable of, judging by past performance. By taking account of production in past periods of activity and allowing for new construction meanwhile, the steel ingot-producing capacity has been estimated in recent months at not over about 50,000,000 tons per annum, but it seems quite probable that in the near future a rate of output nearer 55,000,000 tons will actually be shown.

Readers' Views and Comments

Reversing the In and Out Ratio of the Chemical Engineers

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest your editorial in your issue of Feb. 18, but cannot agree with your point of view. In fact, I believe that the other side of the shield looks entirely different. The American Institute of Chemical Engineers was organized after a preliminary campaign of a year by a committee of five, of which the writer was a member. A list of 700 names of chemists scattered over the United States was prepared as being possible members of the new society. Correspondence with this list was carried on for a year with the object of learning if there was a demand for the organization of the new society. A meeting was held in New York at which the question was discussed, after which a mail vote was taken.

As this was favorable by a large majority, the committee drafted a constitution and effected organization at Philadelphia, June 22, 1908, with forty charter members. During the year sixty more of the 700 joined the organization. Many of the 700 were found on investigation to be qualified by reputation only; others decided not to join the society. The society continued to grow steadily and now has a membership of 357.

You state in your editorial that there are "six outs" to "one in," which would mean that there are 2,500 chemical engineers in the United States who would be eligible for membership in the American Institute of Chemical Engineers. You also state that the "one in" has done nothing to reverse the ratio of membership.

I cannot agree with either of these statements. The Institute has met in various large centers of chemical industry, where many of the "six outs" must reside in order to gain a livelihood by this profession. Before each meeting the local committee has carefully gone over the list of chemists and engineers residing in the section and made a list of the men who could qualify for membership. These men have been invited to apply for membership and generally have done so and been elected.

In this manner a search has been made by a group of local chemical engineers for members in the following centers: Chicago, St. Louis, Cleveland, Detroit, Buffalo, Troy, Boston, Savannah, Los Angeles, San Francisco, Washington, Baltimore, Philadelphia and New York. Undoubtedly younger men are continually coming forward and men in out-of-the-way places are overlooked, but it seems unlikely that six men could have been overlooked for every one who was found. Members of the society are also constantly sending in names or inducing their friends to apply for membership.

The membership of the society will no doubt keep increasing as the ever-growing number of graduates of the chemical courses of our universities and technical schools gain experience and rise into positions of responsibility or demonstrate their ability, but I doubt if a very large and sudden increase in membership is possible unless the standards of membership are lowered.

There is no probability that the present membership will consent to the lowering of the professional or ethical requirements for membership. The society will be of the greatest service to the chemical industry and our country by locating the "outs" who meet the standards of the society and making them desire to become "ins." With its present membership the society can hold very successful meetings and meet all its financial obligations. Nevertheless, it is making an earnest effort to reach all who can qualify.

Another possible method of quickly increasing its membership is to offer another grade of membership such as that of associate membership for those who cannot meet all the professional requirements of education and experience, but who conform to the requirements of the code of ethics. This was considered some years ago, but at that time was not considered advisable.

In this letter I am expressing my personal view of the situation, which does not necessarily reflect the view of the American Institute of Chemical Engineers as a body, as there are quite a number of members of the Institute who have expressed views along the lines of your editorial. J. C. OLSEN.

Brooklyn, N. Y.

Acid Fumes on Riverside Drive

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your amusing comment on "Acid Fumes on Riverside Drive" should be taken in good part by residents on or near the Drive, but I wish to add my plea that something effective be done about it. Being a chemist myself and familiar with all sorts of odors, I am compelled to say they are horrible.

It may be all very well to pass facetious remarks about these assorted odors, and good-humoredly "pass the buck" as to who is to blame, as well as to comment that it is too bad about the "pampered rich" in this section—including several less pampered ones. The point would seem to be that chemistry is a science to alleviate the disagreeable in life as far as possible, rather than to add to it.

I confess that, though living a short distance away from the Drive, only the other night, having just retired, I unexpectedly inhaled several lungfuls of these "delightful odors"—or such as one may cultivate himself to so recognize, as your editorial expresses it—and I enjoyed it and felt impelled to draw deep thrilling drafts of it, as much as most people enjoy breathing sewer gases and those from defective flues. I can heartily recommend the experiment to you.

Incidentally, it may also be beneficial to terraces on Riverside Park to be sprayed with a solution of sulphuric acid 1 : 6,000, which on evaporation would become concentrated to some extent and promote a healthy growth to grass-seedlings. H. S. MUDGE.

New York City.

The Elastic Development of Steel

Description of a Research Undertaken to Salvage a Large Number of Unsatisfactory Bayonet Blades, Which Developed the Fact That Unusually High Strengths Could Be Produced in Medium and High Carbon Steels by High Drawing After Quenching

BY SIDNEY CORNELL

MILITARY men in the Ordnance Departments of the United States and the Allied nations devised tests for semi-finished and finished munition parts that were often unnecessarily and unusually severe, many times representing no strain to which the part would be subjected in actual service. Contracts were taken by our manufacturers with full knowledge of these requirements as specified and stated, but often without knowledge as to what it meant to meet such required tests, and financial losses resulted which will be remembered for a long time. It seems that a more thorough knowledge of the useful strength of metal generally, rather than laboratory tests for condition, might be of immense service in industry and of continual value in the manufacture of commercial goods. Viewed in this light the severe requirements of governments for their war tools can be taken as beneficial, for tests were conducted that commercially never would have been attempted, in order to develop properties in metal parts so as to pass such tests.

Maximum Strength Not at Highest Hardness

Ordinarily the full strength of steel is supposed to be developed at the proper hardening temperature without let-down of the temper. It is also generally assumed that each let-down, or draw, after that hardening weakens the steel, in the sense that it is then not as strong as in the hardened condition.

This view is erroneous, as was discovered by the writer in exhaustive tests made on finished, semi-finished and raw stock required for the manufacture of rifle parts. The useful strength of steel is proportional to the elastic limit of that steel, and inasmuch as this property is susceptible to heat treatment, the most resilient steel can be defined as one that fills the greatest usefulness. The greatest elastic limit, and incidentally also the maximum tensile strength, is not obtainable in steel when hardened only, but is found in the hardened steel when drawn at a more or less closely limited drawing temperature.

Flexure Tests for Bayonets

The English Government required a flexure test for bayonet blades—which subsequently was adopted by the United States—that the hardened and drawn bayonet blade be bent axially 2½ in. (63.5 mm.) out of the vertical, and that the blade must restraighten without a kink or long bow in the cutting edge or back visible to the eye. A vertical lever is used to perform this test, and a pressure of approximately 110 lb. (50 kg.) on the end of a bayonet is required to effect the flexure. The vertical foreshortening of the blade to give a maximum bow of 2½ in. amounts to ¾ in. (19.05 mm.). The test was originally conducted by bending both ways, right and left. It was found that a set in one direction would be corrected by a corresponding set in the other direction, yielding a blade at the end that would pass inspection as straight and of satisfactory temper. Finally instructions were given which required the blade to be inspected after each flexure, right or left, yet adhering to the requirements of perfect straightness.

The Remington Arms Union Metallic Cartridge Co. had serious difficulty in 1916 in meeting these and other requirements. English inspectors would reject blades that were too stiff and which required over 120 lb. (55 kg.) on the vertical lever, although stiff bayonets, so called, usually broke in the test. On the other hand, any blade that set, kinked or had a long bow in it after the flexure test was condemned as "soft." Matters progressed so that although the production of machined, hardened and drawn bayonet blades amounted to over 10,000 per day, the acceptance on the part of the English inspectors became less and less until finally no production in bayonets was made. An accumulation of manufactured but not accepted blades finally amounted to over 1,000,000 English bayonets.

Expert heat-treating recommendations from various experts were used during this time, but no satisfactory blades were made. Irregularities in the steel used could not be blamed for the trouble, as satisfactory blades in quantity had been produced from steel of the same composition. Heat treatment obviously was at fault, and the contentions of the English inspectors in calling blades "soft" undoubtedly had a bearing on the methods of attack on the part of the heat treaters in trying to solve the problem. As a matter of fact the term "soft" was not the correct definition of the trouble.

Characteristics of Rejected Bayonets

The heat treatment given the blades was as follows: Harden in a lead bath at 1,500 reg. F. (816 deg. C.), quench in oil, draw temper at 575 deg. F. (302 deg. C.) in a niter bath for 3 min., and quench in water, followed by a straightening operation by hand.

With a million scrap bayonets to reclaim, a thorough investigation was inaugurated. The steel was found to vary considerably in composition; for instance, carbon varied from 0.75 to 0.95 per cent. Other ingredients in the steel were practically constant, chromium varying from 0.33 to 0.37 per cent. As mentioned before, the composition of the steel could not be blamed for the trouble, as bayonets had been made from all lots that were acceptable, and while all heat treatments in reason had been tried, nothing at this stage would yield a bayonet in quantity that would pass English inspection requirements. Among rejected bayonets there were naturally those in all stages of manufacture, as far as the heat treatment was concerned, including those that were hardened only, those that had not been

hardened and those that had been hardened at 1,500 deg. F. and drawn at 575 deg. F. (816 and 302 deg. C.).

Starting with raw stock, various hardening temperatures were tried upon duplicate pieces, determinations being made on the various physical properties of the steel. The working temperature selected was 1,480 deg. F. (804 deg. C.) as the one which produced the best

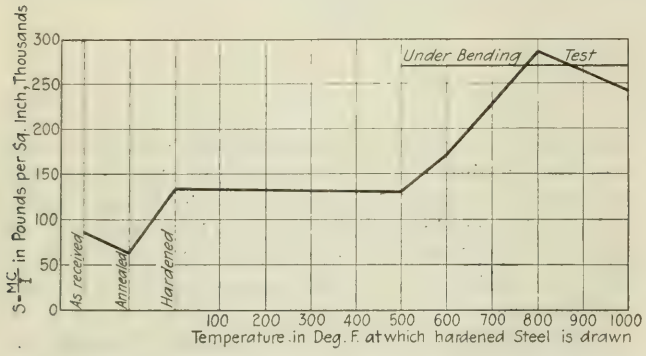

FIG. 1. ELASTIC DEVELOPMENT OF STRENGTH OF BAYONET BLADE STEEL

condition of the hardened steel. This was not radically different from the previous shop practice. To carry the matter further, ultimate tests were made on bars which had been hardened at 1,480 and drawn at various temperatures, and the results plotted. Indications from these tests gave the result that a hardened bar had the greatest elastic limit when drawn at 800 deg. F. (427 deg. C.), very much higher than ordinarily thought reasonable.

A test lot of bayonets that had been rejected as being "soft" and which had been hardened at 1,500 deg. F. (816 deg. C.) and drawn at 575 deg. F. (302 deg. C.) were redrawn at 750 deg. F. (399 deg. C.) and submitted to the English inspectors, who accepted the

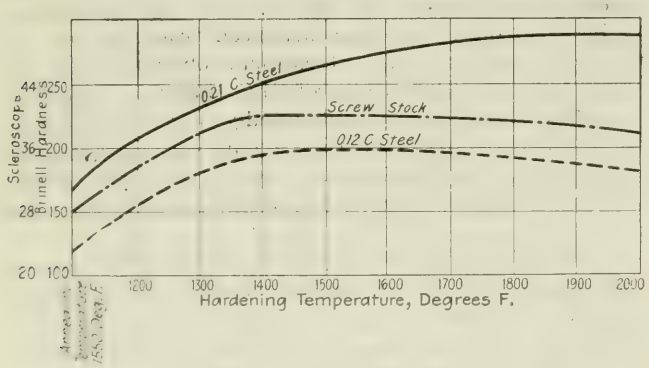

FIG. 2. EFFECT OF HARDENING LOW-CARBON STEELS AT VARIOUS TEMPERATURES

blades. This eventually became known as a "stiffening process." Various precautions in relation to hand straightening were adopted, and on this so-called "stiffening draw" the bayonet department became productive again, the majority of the 1,000,000 rejected bayonets finally being accepted.

A more complete analysis as applied to the strength of the British bayonet blade follows:

When the bayonet is subjected to the ¾-in. flexure test it acts as a column for which the formula is

$$P_c = \frac{IS}{C}$$

P = load, in this case 110 lb.

x = deflection; when foreshortened ¾ in., is 2½ in.

I = moment of inertia about neutral axis.
= 0.0002206 for the average section of the blade.
= 0.0001296 for the weakest section of blade.

C = distance to extreme fiber, average value, 0.114.
= 0.127 at weakest point.

S = extreme fiber stress in lb. per sq.in.

With a blade that met the English requirements of applied load of 110 lb., producing a ¾-in. foreshortening and a 2½-in. deflection in the blade, the maximum value of S is 269,000 lb. (18,912 kg. per sq.cm.).

It was observed that when hardened but not drawn blades were tested they had a tendency to bend slightly before breaking, but that they had no power of recovery. When drawn at 500 deg. F. (260 deg. C.) the recovery after imposing a load was first evident, increasing proportionally up to a maximum of 800 deg. F. (427 deg. C.) and then lessening in intensity.

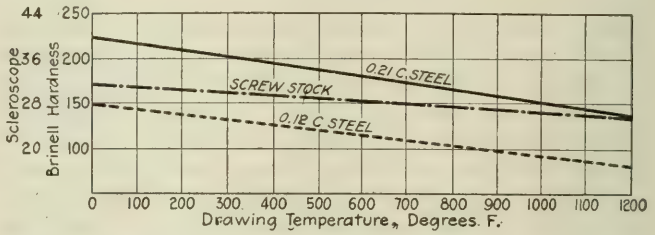

FIG. 3. EFFECT OF ANNEALING HARDEST BARS OF FIG. 2 AT VARIOUS TEMPERATURES

Fig. 1 shows the results of tests on this steel, using duplicate samples for check in all cases, conducted with the object of meeting the theoretical maximum fiber stress under a 110-lb. (50-kg.) load on a bayonet. The maximum elastic limit possible to develop in an extreme fiber by heat treatment is 288,000 lb. per sq.in. (20,200 kg. per sq.cm.), whereas the theoretical elastic limit imposed by the machine is 269,000 lb. per sq.in. Thus there is a leeway of only 18,000 lb., or 6 per cent.

Principal data regarding the bayonet steel follow:

Average Analysis: Carbon, 0.86; manganese, 0.33; silicon, 0.24; phosphorus, 0.017; sulphur, 0.013; chromium, 0.37.

Average Physical Properties: Tensile strength, 97,000; elastic limit, 80,000; elongation, 27 per cent; reduction, 60 per cent.

Ar = 1,260 deg. F.; Ac = 1,335 deg. F.

Standardized Heat Treatment: Pack anneal at 1,550 deg. F. for 22 hr.; lead hardening at 1,500 deg. F. for 4 min.; oil quench; niter draw from 575 deg. F. for 3 min.; first straightening in lead to straw color; second straightening in lead to blue color; stiffening in niter at 750 deg. for 2½ min.; water quench.

Following the important practical results obtained by elastic development in bayonet steel, equally important results were obtained through a similar study of the properties of the various grades of steel used in the manufacture of rifle components. The steels for this use were classified into seven grades, but elastic developments were not made on the first three grades, these being low-carbon material. However, hardening tests were made, and effects of drawing at different ranges were recorded in Brinell hardness with enlightening results.

Fig. 2 shows effect of hardening Grade 1 steel at different temperatures, and Fig. 3 the Brinell hardness after the hardened material had been drawn.

The analysis and physical properties of this grade follow:

C	0.12	Tensile strength	53,800
Mn	0.34	Elastic limit	35,900
Si	0.05	Elongation, per cent	33
S	0.027	Reduction, per cent	71
P	0.013		

Examination of the dotted lines shows the evident fact that quenching from an increasingly higher temperature increases the Brinell hardness of even a 12-point steel up to a flat maximum somewhere between 1,500 to 1,700 deg. F. (800 to 940 deg. C.), above which the hardness is less than after a lower quenching. Taking bars which had received their maximum hardness, annealing at progressively higher temperatures reduces the Brinell hardness in a linear ratio.

Grade 2 steel (screw stock) had the following chemical analysis and physical properties:

C	0.15	Tensile strength	62,200
Mn	0.65	Elastic limit	42,300
Si	0.026	Elongation, per cent	29
S	0.104	Reduction, per cent	61
P	0.081		

Its Brinell hardness after a series of quenchings and systematic drawings is plotted in Figs. 2 and 3 in dot and dash. The characteristics of the curves are exactly similar to those of soft-low-sulphur steel, (Grade 1).

Grade 3 steel of the following analysis was treated in the same manner:

C	0.21	Tensile strength	67,000
Mn	0.45	Elastic limit	48,000
Si	0.11	Elongation, per cent	28
S	0.039	Reduction, per cent	65
P	0.035		

Fig. 2 shows that its hardness, originally higher than the two other steels, increases at a rate which indicates a flat maximum near 2,000 deg. F., where the quenching experiments stopped. However, the effect of drawing such metal after a quenching from

1,650 deg. was more pronounced than before, as indicated by a steeper slope of the line representing hardness against drawing temperature.

Determinations of elastic development were made on Grade 4 steel and the grades to follow. The rise in strength under appropriate heat treatment is plainly evident. The properties of Grade 4 in its condition as received is as follows:

C	0.35	Tensile strength	90,300
Mn	1.28	Elastic limit	61,700
Si	0.19	Elongation, per cent	22
S	0.034	Reduction, per cent	64
P	0.054		

Fig. 4 shows in a full line the hardness after annealing at 1,550 deg. C. and after quenching this normalized material from various temperatures. The hardness is shown to rise continually up to the highest temperatures experimented with. Samples after hardening from 1,650 deg. C. were then drawn at various temperatures. Fig. 5 shows the results in a full line. Hardness in this case is a mean line between a higher graph showing scleroscope numbers and a lower graph the Brinell

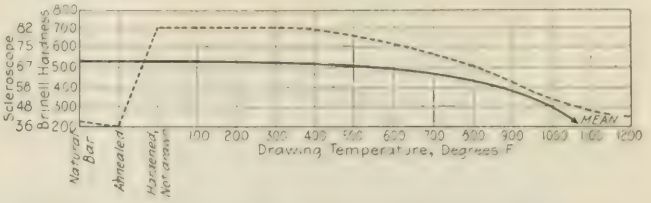

FIG. 5. DECREASE OF HARDNESS UPON DRAWING

Full line represents 35-point carbon steel. Dotted line represents smokeless barrel steel.

numbers. For instance, the scleroscope hardness of the hardened specimen drawn at 600 deg. is 70, while the Brinell number is 480.

A number of transverse specimens were then hardened by oil-quenching from 1,510 deg. F. These were then drawn at various temperatures, tested, and the physical properties under the ordinary slow deflection test determined and plotted as in full lines in Fig. 6. Contrary to the general assumption, reheating even to relatively high temperatures increased the ultimate strength and elastic limit.

Grade 5 steel is the so-called smokeless barrel steel on

which a great deal has been written, and which has caused a great deal of trouble in its fabrication. Its analysis is:

C	0.53	S	0.052
Mn	1.25	P	0.064
Si	0.27		

The physical properties of the steel as received and after routine heat treatment are:

AS RECEIVED

Tensile strength	120,300	Elongation, per cent	16
Elastic limit	73,000	Reduction, per cent	44

HEAT-TREATED BARRELS

Tensile strength	132,400	Elongation, per cent	12
Elastic limit	115,500	Reduction, per cent	48

This steel when hardened from different temperatures gives the results plotted in Fig. 4 in dotted lines, the Brinell and scleroscope being the measures of hardness. A line is traced quite similar to that for Grade 4 steel, but somewhat higher on the hardness scale.

The bar or billet as it came from the rolling mill, after it had been annealed and hardened from the best temperature and then drawn from a series of rising temperatures, gave results shown dotted in Fig. 5. Results again are quite similar to those for steel of the previous grade, shown in full lines. However, when subjected to elastic development, the elastic limit and

ultimate strength (practically the same value) increase up to a drawing temperature of 800 deg. F., and then decrease. This is shown in Fig. 6 in dotted lines, and its difference from that of Grade 4 is striking.

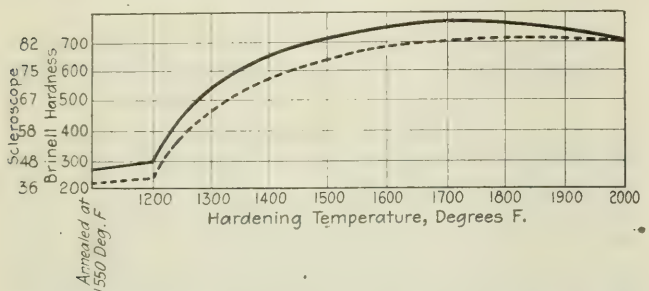

FIG. 7. HARDNESS VERSUS HARDENING TEMPERATURE FOR HIGH-CARBON STEEL

Full line represents Grade 6 (0.60 carbon). Dotted line represents Grade 7 (0.92 carbon).

Grade 6 steel of higher carbon content analyzed:

C	0.60	Tensile strength	109,800
Mn	1.25	Elastic limit	60,300
Si	0.275	Elongation, per cent	17
S	0.037	Reduction, per cent	51
P	0.062		

The effect of hardening is shown in Fig. 7, temperatures up to 2,000 deg. F. being used, and the Brinell and scleroscope the measure.

The effect of drawing at different temperatures is shown in Fig. 8 in full lines. Note that this steel comes nearest to obeying the rules as indicated by various authorities, viz., that the hardened and not

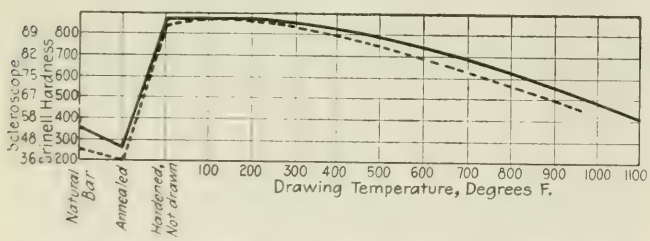

FIG. 8. DECREASE OF HARDNESS UPON DRAWING

Full line represents Grade 6 (0.60 carbon). Dotted line represents Grade 7 (0.92 carbon).

drawn steel is the strongest. However, the measure is Brinell hardness, not elastic limit or tensile strength. That in many cases there is not a constant relation between these properties is shown in Fig. 9. Here the elastic development is clearly shown, this steel reaching a maximum strength when drawn at 800 deg. F.

Grade 7 steel has the following analysis:

C	0.92	Tensile strength	79,700
Mn	0.36	Elastic limit	50,300
Si	0.18	Elongation, per cent	25
S	0.023	Reduction, per cent	55
P	0.022		

The effect of hardening temperature is illustrated in Fig. 7 in dotted lines, the measure again being Brinell and scleroscope.

The effect of drawing temperature is given in Fig. 8, while the elastic development is clearly illustrated in Fig. 9. The ultimate strength increases in a well-defined relationship to the elastic limit; maximum development is attained at approximately 650 deg. F.

It is believed that the foregoing data in relation to the effect of temperatures on the heat treatment of steel will be new to many persons, and it will fill a need in the heat-treatment department of smaller plants where facilities for conducting such an investigation are not at hand. The range of composition of the steels covers from 0.10 to 1 per cent carbon in eight steps, so that properties of any steel as usually met with can be approximated.

The analyses of the steels as given represent averages of not less than twenty-five check analyses conducted on the material as received. The specified chemical re-

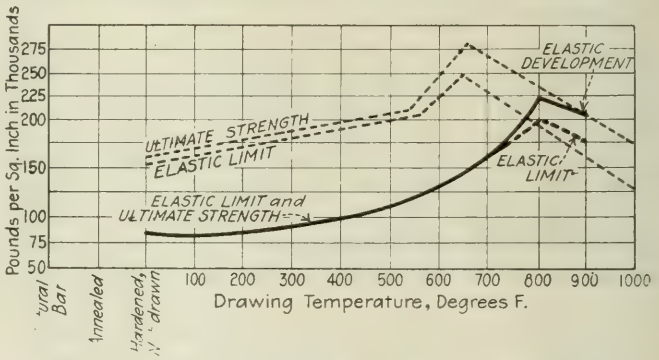

FIG. 9. ELASTIC PROPERTIES OF HARDENED AND DRAWN STEELS

quirements for the seven grades of steel discussed were as tabulated above, attention also being drawn to the Ac_1 and Ar_1 points as determined, and to the B.t.u. liberation at the Ar_1 point as calculated.

Conclusion

Heat treatment is far from being an exact science. There must be a mass of data in existence in this country the authors of which show a hesitancy toward presenting it to criticism in the technical press. It is suggested that these authors present their data, and that they receive a fair reception on the part of editors. Many articles on heat treatment are remarkable by their similarity, dealing with metallography in particular, and it is thought that the reason for this state of affairs is that all of the men engaged in "heat treating" for a livelihood know that there is no real working treatise on the subject of "heat treatment of steel," and the writers among them are making a start at one that will be complete. Why not publish observed facts, which may bring about discussion and undoubtedly will be a step toward betterment in this art which never can be absolutely scientific?

New York City.

Electric Furnace Smelting of Montana Manganese Ores*

Balance Sheet of 10-Day Electric Furnace Test—Discussion of Slag and Furnace Losses, Together With a Method of Calculating Charges—Description of Electric Furnace Plant at Great Falls

By E. S. BARDWELL
Metallurgist, Anaconda Copper Mining Co.

DURING the year 1918 there was produced in the United States 304,366 long tons of manganese ore containing over 35 per cent manganese[1]. Of this amount, Montana alone produced 199,932 tons, or over 65 per cent of the total tonnage. Practically all of this ore came from the Philipsburg and Butte districts; 127,415 tons from the Philipsburg district, 72,381 tons from the Butte district, with only 136 tons reported as coming from other parts of the state. The armistice caused an immediate curtailment of manganese mining in Montana due to the ability of the Eastern steel plants to secure supplies of manganese ore again from foreign sources.

Prior to 1914 less than 2 per cent of the total high-grade manganese ore used in the United States was mined in this country. The manganese production of the State of Montana in 1918 was greater than the total imports to this country for the year 1911 and would represent a substantial percentage of this country's normal requirements.

In view of these facts, the importance of this potential source of manganese cannot fail to be recognized and a discussion of the problems of smelting these ores in the electric furnace should be of interest.

Character of Ores

The Montana ores are low in phosphorus and iron and admirably suited for the production of 80 per cent ferromanganese.

In the Butte district the Emma mine is the chief producer. The output of this mine during the war reached a maximum of 10,000 tons of rhodocrosite ore a month, the greater part of which was shipped to Eastern consumers.

A typical analysis of this ore would be as follows:

	Per Cent		Per Cent
Moisture	2.61	BaO	0.00
MnO	46.87	CO_2	33.56
FeO	2.68		
SiO_2	6.19		95.70
Al_2O_3	1.18	Undetermined	4.30
CaO	0.00		
MgO	2.61		100.00

The Philipsburg ores differ from those of the Butte district in that they are higher in silica and contain manganese principally in the form of the psilomelane, a hydrated oxide of manganese of more or less indefinite composition.

An average analysis of this ore would be about:

	Per Cent		Per Cent
Moisture	9.73	BaO	
MnO_2	50.10	Loss on ignition	12.80
MnO	3.83		
Fe_2O_3	2.90		99.44
SiO_2	18.07	Undetermined	.56
Al_2O_3	2.01		
CaO			100.00
MgO			

By washing it is possible to reduce the silica content of the Philipsburg ores to at least one-half the percentage stated above, with a corresponding increase in manganese content.[2]

Electric Furnace Plant at Great Falls, Mont.

During 1918 the Anaconda Copper Mining Co. erected at Great Falls, Mont., an electric furnace plant capable of producing ninety tons daily of 80 per cent alloy. The first of five furnaces was started in September. Three furnaces were ready for operation at the time the armistice was signed, shortly after which time operation ceased due to lack of market for the product.

The furnaces consist of an open-top, shallow brick shaft 28 x 14 x 9 ft. (8.5 x 4.3 x 2.7 m.) in outside dimensions. Outer walls are of red building brick with an inner firebrick lining. This shaft has a tamped lining composed of dead-burned magnesite with pitch as a binder. The tamped lining is 3 ft. (91 cm.) in thickness at the bottom of the crucible and is brought up the sides to a point about 18 in. (46 cm.) above the tap-hole level. Cooling pipes are provided in the bottom through which air for cooling the bottom is circulated. Inner dimensions of the crucible at the middle section are 22 x 9 ft. x 6 ft. deep (6.7 x 2.7 x 1.8 m.). The furnaces are operated on 60-cycle, three-phase alternating current. Two 24-in. (61-cm.) round amorphous carbon electrodes are used in a common holder on each phase. Electrodes are spaced 3 ft. (0.91 m.) between centers in the holders and the pairs about 5 ft. (1.52 m.) on centers.

The holders originally provided were discarded on account of mechanical difficulties and a simple holder devised made in two entirely independent halves held together by pins and wedges. A long "fish-tail" cast integral with the holder makes it possible to avoid bringing cables out over the furnace where they will be subjected to the hot gases. Water cooling is brought about by a coil of pipe properly formed and cast in, and water connections for each half are independent. The holder is supported by yokes which serve to keep the chains used for raising and lowering the holders up out of the heat. Winches for raising and lowering the electrodes are placed upon the bridge supporting the holder and electrodes, which bridge is insulated from the furnace superstructure by means of vitrified brick interposed between. No trouble was experienced from failures of insulation during the time the furnaces were operated. The holders themselves were cast in sand molds from phosphor-copper and require practically no machine work. We found the contact surface ample and the holder sufficiently flexible

*Paper presented at the thirty-seventh convention of the American Electrochemical Society, Boston, April 9, 1920.

[1] *Mineral Industry*, vol. 27 (1918), p. 460.

[2] A brief account of concentrating methods employed is given in CHEM. & MET. ENG., vol. 18, p. 625, June 15, 1918.

to take care of the inequalities in size often existing between the two electrodes in the holder. A loosely fitting sheet steel sleeve was provided to slip down over the electrode. This rested on top of the holder and prevented the electrode being eaten away above the holder by the hot gases.

When slipping electrodes the wedges were easily loosened, the holder raised and again clamped. The time required for slipping electrodes was not over 10 min. No attempt was made to protect the electrode exposed between the holder and the charge except to keep the holder as close down to the top of the charge as was feasible.

Substation

The substation, from which electrical energy is supplied to the furnaces, is located immediately back of the furnaces. It received power at 110,000 volts from nearby hydro-electric plants of the Montana Power Co. Two 12,000 k.v.a. General Electric transformers serve to reduce the voltage from 110,000 to 6,600 volts, at which voltage it is delivered to the furnace transformers. Each furnace is equipped with one General Electric polyphase transformer rated at 5,630 k.v.a., provided with taps on the high tension side for 85, 100, 115 and 130 volts. The furnaces were operated with a no-load voltage of 115 volts. The average input under these conditions was 3600 kw. The power factor was about 80 per cent.

The operating panels are arranged in a gallery overlooking the furnaces. Provision is made for either hand or automatic control. The automatic regulators are of the General Electric type originally designed to operate on current. We found it advantageous, however, to keep the voltage on the separate phases balanced rather than the current and the necessary alterations were made in the apparatus to enable us to regulate on the voltage between phases and ground. With this change the automatic control proved highly satisfactory, holding the load constant under all conditions met with in operation with very little attention on the part of the operator.

Charge Mixing

The weighing and mixing division is so arranged that four operators can, in one shift, weigh and mix sufficient charge to keep five furnaces in operation for 24 hr. This would hardly be feasible were the plant treating a large variety of ores, but given a constant supply of ore of a uniform grade, little or no difficulty has been experienced. Mixed charge is delivered by belt conveyors to the mixed charge bin, whence it is taken in boats by traveling crane and dumped into charge hoppers at the furnace.

The charge consists of ore, limerock, coal, coke and iron ore. The only manganese ore treated at Great Falls is the Butte rhodocrosite ore from the Emma mine. The charge treated was as follows:

	Lb.		Lb.
Ore	560	Coke	50
Limerock	99	Iron ore	12
Coal	160		

When the furnaces were first started coal only was used as a reducing agent. We soon found, however, that owing to the fact that the rhodocrosite decrepitates when heated this gave us too compact a charge. Primarily to do away with this difficulty, we substituted for a part of the coal an equivalent amount of blast-furnace coke based, of course, on the relative fixed carbon content of the two materials. With this change the furnace operated very smoothly with only occasional boils. Coke alone was tried, but with this we could not keep the electrodes down in the charge. The proportions of coal and coke indicated above were finally determined upon as being the best under our conditions.

The furnaces are tapped at intervals of about 1½ hr. The slag and metal run into ladles, the slag is skimmed into a slag sluice and the metal cast by machine.

The plant was operated for such a short time and under such adverse conditions that it is impossible to give accurate metallurgical results. The results were on the whole, however, satisfactory. The loss by volatilization was not over 15 per cent and the recovery of manganese in metal between 75 and 80 per cent.

Electric Furnace Test on Montana Ores

Materials

The ore used in the test about to be described consisted of a half and half mixture of ores from the Philipsburg and Butte districts. This material was very carefully bedded, sampled and analyzed. The analysis of the mixture gave results as follows:

	Per Cent		Per Cent
Moisture	5.03	BaO	0.03
MnO_2	23.92	MgO	1.15
MnO	26.37	CO_2	16.67
FeO	1.14	Comb. H_2O	6.43
Fe_2O_3	1.40	Undetermined	2.43
SiO_2	13.48		
Al_2O_3	1.95		100.00
CaO	.....		

Coal was used as a reducing agent. This coal was of the following analysis:

	Per Cent		Per Cent
H_2O	7.82	Al_2O_3	0.73
Fixed carbon	54.43	MgO	0.34
Volatile hydrocarbons	31.73	Undetermined	0.67
FeS_2	1.84		
SiO_2	2.44	Total	100.00

As flux a very pure marble was employed. This contained 55.0 per cent CaO and 43.2 per cent CO_2.

It was necessary to add iron in order to make 70 per cent ferromanganese. The iron was added in the form of turnings which were not analyzed but which for the purpose of the test we assumed to contain 100 per cent iron.

The Furnace

The furnace upon which this test was conducted was of the rectangular open-top type. It consisted of a steel shell 18 ft. x 9 ft. x 8 ft. 8 in. (5.5 x 2.7 x 2 m.) outside dimensions with carbon lining approximately 30 in. (76 cm.) thick at the bottom of the crucible and 18 in. (46 cm.) on the sidewalls. The transformer equipment consisted of 3 single-phase Pittsburgh transformers each rated at 667 k.v.a. and connected Δ/Δ. These transformers were provided with taps for 65, 75 and 85 volts and during the test were operated at no-load voltage of 75 volts. Three 24-in. round amorphous-carbon electrodes were used in water-cooled top holders. Motor-operated winches served to move electrodes up and down, but the furnace was not provided with automatic regulators. The furnace was tapped at intervals of about 1¼ hr. The slag and metal was allowed to flow into sand pits, where it solidified, and was then removed to the yard, where the slag was separated and metal weighed and loaded into cars.

The furnace charge was varied slightly from time to time during the test but was substantially as follows:

	Lb.		Lb.
Ore	500	Limerock	90
Coal	150	Turnings	30

This charge gave us metal containing 70.9 per cent manganese. The coal is, however, too high and the limerock too low for best results. A method for calculating the charge will be given later on.

Balance Sheet

The furnace was operated on the above charge for a period of 274 hr., during which time a total of 501,000 lb. of the ore mixture was smelted, yielding 186,419 lb. of metal containing 70.9 per cent manganese. The slag from the furnace was kept separate from the slag resulting from other furnace operations and was weighed, sampled and analyzed. The complete balance sheet follows:

	Charge	Products		
Ore, 501,000 lb.		Metal	Slag	Gases
Mn	178,096	132,171	4,482	41,443
Fe	8,831	8,831	.....	.....
Si	31,501	15,286	16,215	.....
Al_2O_3	9,790	.....	8,342	.....
BaO	150	.....	925	.....
MgO	5,753	.....	4,313	.....
CO_2	83,517	.....	.....	83,517
H_2O	57,415	.....	.....	57,415
Comb. O_2	115,673	.....	20,588	95,085
Flux, 91,100 lb.				
CaO	50,105	.....	47,162	.....
CO_2	39,355	.....	.....	39,355
Coal, 147,890 lb.

Volatiles	46,926	.....	.....	46,926
H_2O	11,567	.....	.....	11,567
Iron, 29,796 lb.				
Fe	29,796	19,540	.....	10,256
Totals, 769,786		186,233	102,686	457,953

Metal and slag represent actual analyses.
Only 2.97% unaccounted for by balance sheet.

Analyses of metal and slag were as follows:

Slag	Per Cent	Metal	Per Cent
Mn	4.26	Mn	70.9
SiO_2	34.37	Fe	15.9
Al_2O_3	7.93	Si	8.2
CaO	44.83	C	4.9
MgO	4.10		
BaO	0.88		99.9
	96.37		

Ratio ore to metal	2.68
Per cent total manganese in metal	74.21
Per cent total manganese in slag	2.51
Per cent total manganese in gases	23.28
Per cent of charge accounted for in metal	24.22
Per cent of charge accounted for in slag	13.67
Per cent of charge accounted for in gases	62.11
Pounds slag per ton of metal	1,129
Pounds gas per ton of metal	5,130
Pounds electrode per ton of metal	150
Kilowatt-hours per ton of metal	4,879

Calculation of Theoretical Power Requirement

From our balance sheet it is possible to compute a heat balance of the furnace. In so doing we shall assume:

1. That the slag and metal contain at tapping 600 and 400 calories of heat respectively.

2. That the gases escape from the furnace at temperature of 300 deg. C.

The heat available is principally the heat of oxidation of the carbon plus that furnished by the electrical energy used. The charge gives up to the carbon, as shown by the balance sheet, 95,085 lb. of oxygen. The 71,360 lb. of carbon burned would require 71,360 × (16 ÷ 12) = 95,147 lb. of oxygen to burn to CO or practically all the carbon is burned to CO. Carbon monoxide is capable of reducing manganese dioxide to the monoxide, and it appears probable that a certain amount of reduction takes place in this manner. The balance of the carbon monoxide escapes as such and burns at the top of the charge.

The heat of formation of the slag will be taken as 150 calories per lb. of contained SiO_2 and Al_2O_3. The heat of combustion of carbon with manganese is about 825 calories per lb. of carbon combined, while the heat of formation of manganese silicide is 1,693 calories per lb. of silicon combined.

HEAT AVAILABLE FOR ENTIRE TEST

	Pound Calories
Supplied by electric current	*X*
Oxidation of C to CO = 71,360 × 2,430	173,404,800
Formation of silicate slag = 44,500 × 150	6,675,000
Formation of Mn_3C = 9,135 × 825	7,536,375
Formation of Mn_7Si_2 = 15,286 × 1,693	25,879,198
Total	*X* + 213,495,373

HEAT DISTRIBUTION

	Pound Calories
Reduction of Mn from MnO_2 76,656 × 2,278	174,622,368
Reduction of Mn from MnO 96,969 × 1,653	160,289,757
Reduction of Fe from FeO 4,409 × 1,173	5,171,757
Reduction of Fe from Fe_2O_3 5,692 × 1,746	9,938,232
Reduction of Si from SiO_2 15,286 × 7,000	107,002,000
Calcination of $CaCO_3$ and $MnCO_3$ 122,872 × 1,026	126,066,672
Distillation of volatile from coal 46,926 × 800 (assumed)	37,540,800
Expulsion of moisture 68,982 × 600	41,389,200
Sensible heat in gases*	36,003,000
Sensible heat in slag 105,201 × 600	63,120,600
Sensible heat in metal 186,419 × 400	74,567,600
Total heat energy required	835,711,986

Equating heat input and outgo

$$213{,}495{,}373 + X = 835{,}711{,}986 \text{ lb. cal.}$$
$$X = 622{,}216{,}613 \text{ lb. cal.}$$

But 1 Kw.-hr. = 1,897 lb. cal.

hence required electrical energy, no allowance being made for radiation, is 328,000 kw.-hr.

During the test there was produced 93.2 tons of ferromanganese. The theoretically required power is therefore

$$\frac{328{,}000}{93.2} = 3{,}520 \text{ kw.-hr,}$$

or, say, 3,500 kw.-hr. per short ton.

PERCENTAGE HEAT DISTRIBUTION

	Per Cent Total Heat Required
Reduction of manganese	40.1
Reduction of iron	1.8
Reduction of silicon	12.8
Calcination of $CaCO_3$ and $MnCO_3$	15.1
Distillation of volatile from coal	4.5
Expulsion of moisture	4.9
Sensible heat in gases	4.3
Sensible heat in slag	7.6
Sensible heat in metal	8.9
	100.0

From the above it would at first appear that considerable saving might be effected by calcining the ore and limerock previous to charging it into the furnace. This assumption, however, does not seem to be borne out in practice. The greater part of the work of calcination is brought about in the upper part of the charge column utilizing heat which would otherwise be lost. Some economy of operation should, however, result and the practicability of the operation should be carefully investigated.

*Sensible heat in gases at 300 deg. C

	Kilogram-Calories
CO, 166,445 lb. = 60,000 cu.m. × 0.311	18,660
CO_2, 122,872 lb. = 28,148 cu.m. × 0.436	12,273
H_2O, 68,982 lb. = 38,630 cu.m. × 0.34	13,134
Vol. from coal, 46,926 lb. = 21,285 cu.m. × 0.311	6,620
Vol. manganese, etc., 42,472 lb. = 4,816 cu.m. × 0.8	3,863
	54,550
54,550 × 300	16,365,000

From the above computation we are enabled to compute the heat efficiency of the furnace tested to have been 71.7 per cent. This figure is very good for a furnace of the size upon which the test was conducted.

The heat loss is due of course in part to radiation of heat from the furnace itself and in part to I^2R losses. A test carried out on a similar furnace showed 40 per cent of the heat loss to be due to radiation and 60 per cent to the I^2R losses. Of this 60 per cent the following distribution may be made:

	Per Cent		Per Cent
Transformers	17.5	Contacts	37.5
Conductors	30.0		
Electrodes	15.0	Total	100.0

The above analysis gives us, I think, a very comprehensive idea of the heat requirements of an electric furnace producing ferromanganese. Due to lack of accurate data certain assumptions had to be made in computing the theoretically required power, but the result obtained is sufficiently accurate for all practical purposes.

Slags

In studying electric furnaces producing ferromanganese my attention was called to the great variety of slags produced. It seemed worth while to investigate the question of slags with the idea in mind of seeing whether or not means could be found to calculate a charge which would give a slag of low manganese content. From a considerable number of samples, eight typical slags were selected and carefully analyzed.

No. 1. A hard gray slag containing ferromanganese inclusions.

No. 2. A medium green hard slag with few, if any, metal inclusions.

No. 3. A dark green hard slag with little in the way of inclusions.

No. 4. A high-lime air-slacking slag.

No. 5. A high-lime air-slacking slag.

No. 6. A light-gray glassy slag.

No. 7. A light-green hard slag.

No. 8. A light pea-green hard slag.

ANALYSES OF SLAG SAMPLES

	1	2	3	4	5	6	7	8
SiO_2	28.2	31.5	26.6	34.4	22.4	30.9	31.9	32.9
FeO	1.2	0.7	1.0	0.1	0.1	1.1	1.3	0.8
Al_2O_3	17.3	8.0	9.6	7.7	6.8	10.0	10.1	8.7
CaO	41.4	35.7	31.1	42.2	46.8	37.8	35.3	36.0
MgO	7.6	1.8	1.1	1.8	4.0	10.2	10.4	2.1
BaO	0.4	1.3	4.8	1.1	0.2	0.2	0.3	1.2
Mn	2.1	14.5	19.9	8.1	5.3	4.7	5.8	12.2
Total	98.2	93.5	94.1	95.4	85.6	94.9	95.1	93.9

It will be noted that in this collection of slags we have two types only as regards their physical condition, *i. e.*, hard slags and air-slacking slags. Air-slacking is due to a composition such that calcium orthosilicate, $2CaO.SiO_2$ separated as one of the phases. The orthosilicate crystallizes in three distinct forms, the alpha-form, stable above 1,410 deg. C. to the melting point, the beta-form, stable between 675 and 1,410 deg., and the gamma-form, stable below 675 deg. C. The transformation of the beta-orthosilicate into the gamma-form is accompanied by a 10 per cent volume increase. It is this volume increase, therefore, that accounts for what I have termed the air-slacking of slags 4 and 5: The presence of much magnesia in the slag tends to prevent this latter transformation.

Manganese occurs in the slags in three ways: first, as ferromanganese inclusions; second, as manganese silicate, and third, as manganates or manganites of calcium or in some cases as oxides of manganese in solution in the slag. Any slag that is insufficiently fluid will contain more or less in the way of ferromanganese inclusions. Lack of sufficient carbon to reduce the manganese will, of course, promote the formation of manganates and manganites. Excess silica seems to tend to form silicates even when sufficient carbon is at hand to reduce all the oxides of manganese to metal.

A green slag is evidence of lack of sufficient carbon to carry out the reduction of the manganese oxide. The depth of color is an indication of the amount of manganese present. When there is an excess of silica present, slags are sometimes pink due to the presence of manganese silicate.

An excess of reducing agent tends to the formation of calcium carbide and graphite accretions in the furnace. This may in some cases be carried so far as to leave an excess of silica and promote the formation of manganese silicates in the slag; in any event, there is a waste of power and the accretions interfere with operations, rendering it necessary to shut down and dig out the furnace at frequent intervals. The best slags seem to have a composition of about 30 per cent silica, 15 per cent alumina and 50 per cent lime plus magnesia, or better, should have an oxygen ratio, alumina being counted as base, of between 1.25 and 1.50. A slag of this composition is easily fusible, separates well from the metal and is economical to make.

Volatilization Losses

Under volatilization in the balance sheet has been included losses by dusting. In the electric furnace losses by dusting should not be large. Some loss by dusting is caused by occasional blows and boils occurring during periods of irregular operation. That the greater part of the manganese lost except for that contained in the slag is volatilized in some manner is very evident. In just what form or forms the manganese is volatilized I do not know nor have I ever seen a satisfactory explanation of the phenomenon. It is usually considered that the manganese is volatilized, as the metal escaping from the furnace burns at the surface of the charge to the oxide. The presence of brownish fumes in the gases escaping from the furnace would readily lead one to this conclusion. On the other hand, I have observed furnaces running with a comparatively cool top when there was no evidence of these brownish fumes but which were still volatilizing a considerable amount of manganese.

In the case of furnace volatilizing considerable amounts of manganese, I have observed that considerable amounts of iron also vanish, in fact, based on the relative proportions of iron and manganese in the charge, more iron than manganese is volatilized.

An attempt to reduce the manganese content of the slag by using more carbon is accompanied in most instances by an increased volatilization loss.

In order that we may learn how to minimize our volatilization losses, it is important that we should know in what manner manganese is volatilized.

Excessive volatilization will occur inevitably in a furnace improperly designed as regards heat distribution. A furnace must be properly proportioned with reference to the power input in order to operate efficiently. Given such a furnace, however, we often find that the volatilization losses vary widely from time to time. The theory has been advanced that manganese and iron are volatil-

ized as carbonyls which in the hot top furnace burn to the oxides of the respective metals and carbon dioxide, and in the case of furnaces operating with a cooler top may pass off unnoticed as gases. This fits in very nicely with my observations with reference to addition of carbon, and its effect on increased volatilization. The formation of carbonyls if such exist may be due to the formation of carbides of iron and manganese which in turn react with the metallic oxides present, reducing them and at the same time setting free carbonyls.

As in many cases the slags produced by the electric manganese furnaces have a distinct fluxing value, it might be well to throw more manganese into slag by cutting the carbon on the charge provided the combined loss in manganese is not increased thereby.

Calculation of Charge

The charge will be calculated on the following basis:

1. We shall assume that the metal is to contain 70 per cent manganese, 5 per cent carbon, 5 per cent silicon and 20 per cent iron.

2. The charge will be calculated on the basis of 100 lb. of ore.

3. In proportioning the amount of reducing agent required, we shall assume that the fixed carbon only is available for bringing about the reduction of the several metals. As has been pointed out, this is not a correct assumption, as some reduction is very evidently effected by the carbon monoxide gases and possibly the volatile hydrocarbons. It gives us, however, a starting point and in the absence of complete data as to the reducing power of the fuel used, enables us to calculate the charge.

4. The magnesia will be calculated to $2MgO.SiO_2$, alumina to $Al_2O_3.3CaO.2SiO_2$, and the balance of the silica to $2CaO.SiO_2$.

5. Sufficient iron will be added to give metal containing 20 per cent iron, assuming 80 per cent of the manganese to enter the metal.

CARBON REQUIREMENT

C to reduce MnO_2 to Mn	$\frac{23.92 \times 24}{87} =$	6.60
C to reduce MnO to Mn	$\frac{26.37 \times 12}{71} =$	4.46
C to reduce FeO to Fe	$\frac{1.14 \times 12}{72} =$	0.19
C to reduce Fe_2O_3 to Fe	$\frac{1.40 \times 36}{160} =$	0.31
C to reduce SiO_2 to Si	$\frac{4.34 \times 24}{60} =$	1.73
C to supply metal	=	2.02
		15.31

We shall, therefore, require $\frac{15.31}{0.5443} = 28.1$ units of coal per 100 units of ore.

In the ore and coal we shall have to flux after allowing for the 4.34 units of silica which is reduced and which enters the metal:

9.82 units	SiO_2	1.24 units	MgO
2.15 units	Al_2O_3	0.03 units	BaO

Now, figuring MgO to $2MgO.SiO_2$, we get

$$\frac{1.24 \times 140}{80} = 2.17 \text{ units } 2MgO.SiO_2$$

Figuring Al_2O_3 to $Al_2O_3.3CaO.2SiO_2$

$$\frac{2.15 \times 388}{102} = 8.18 \text{ units } Al_2O_3.3CaO.2SiO_2$$

Then, 6.31 units of SiO_2 remain to be fluxed.

Calculating to $2CaO.SiO_2$, we have

$$\frac{6.31 \times 172}{60} = 18.1 \text{ units } 2CaO.SiO_2$$

Total lime required = 15.24 units, or marble on charge would be

$$\frac{15.24}{0.55} = 27.7 \text{ lb. per 100 lb. ore}$$

We have in slag

	Theoretical Steel—Per Cent
9.82 units SiO_2	34.4
2.15 units Al_2O_3	7.6
1.24 units MgO	4.4
0.03 units BaO	0.1
15.24 units CaO	53.5
28.48	100.0

Assuming 80 per cent recovery of manganese the iron required would be 6 lb. per 100 lb. ore.

Our charge, based on 500 lb. of ore, would then stand

	Lb.		Lb.
Ore	500	Limerock	140
Coal	140	Turnings	30

If no special attempt is made to keep the silicon down to 5 per cent, the lime can be cut to a considerable extent, depending upon the amount of silicon permissible in the metal. If low silicon metal is desired, the coal may be cut, leaving the limerock as above. The coal may in any event be reduced somewhat, as has been pointed out previously, but this should be done a little at a time and the furnace watched carefully. At least 24 hr. should be allowed to elapse between such changes. The calculation of the charge can at best only serve as a guide. Much depends upon the characteristics of the furnace that is being operated. The operator must watch his furnace and vary the charge to suit operating conditions.

New British Plans for Trade Information

The Overseas Trade Department is now preparing for publication manuals or handbooks of commercial information relating to various countries. These publications, which are intended to be books of reference for British traders, give the stable features of the country described—resources, products, commercial treaties and law, transport, and trading methods. The manuals for France and Argentina are nearly ready, and some material has been accumulated for those on Brazil, Italy, and Greece. They are prepared by the economic and editorial section.

The department is also preparing to issue periodic reports sent in by commercial diplomatic officers on instructions issued last year. These are to take the place of the old consular reports, which were issued periodically from 1858 until the war, but will be a systematic survey of each of the principal countries as a whole. When the organization of the economic and editorial section is complete, it will also be possible to prepare special economic memoranda on topics of outstanding interest which are not otherwise provided, either because of the technical research involved or because of their broad international character. It is hoped that one of the principal categories of such studies will be international commercial finance. At present the section is dealing with reports upon the economic and trade situation in countries severely affected by the war. Sir Hubert Llewellyn Smith called for special reviews of this character, and these are now being brought together so as to form a general survey of European trade conditions at the close of the year 1919.

The German Nitrogen Syndicate*

A Discussion of Germany's Capacity for Nitrogen Fixation Before and After the War, and Her Present Independence—Frank Recognition of the Effect of Foreign Competition—Description of Government Control of Production, Distribution and Prices

By PROF. N. CARO

ONE of the most far-reaching achievements of the German War Ministry was the development of the nitrogen industry. While Germany before the war was obliged to import something like 100,000 tons of nitrogen a year in order to meet the requirements of her agriculture and industries amounting to 220,000 tons per year, she is now able to meet her greatly increased demands solely from domestic manufacture. Before the war, there was produced in Germany each year:

	Tons Nitrogen
1. In coke ovens, gas plants, and other byproduct installations, about 550,000 tons of ammonium sulphate, equal to	110,000
2. In lime-nitrogen plants about 50,000 tons of lime-nitrogen, equal to	10,000
Total	120,000

The nitrogen plants built during the war for the production of lime-nitrogen and ammonia when completed will be in a position to produce about 380,000 tons of nitrogen per year, so that the total yearly production will amount to over 500,000 tons of nitrogen. This output of nitrogen will be divided thus:

	Tons Nitrogen
Ammonia, by the Haber process	300,000
Ammonia from coke ovens, gas plants, and other byproduct installations	110,000
Lime-nitrogen	100,000
Total	510,000

The government took an active part in the increase in nitrogen production secured during the war. It owns the Imperial Lime Nitrogen Plants in Piesteritz and Chorzow, which have a yearly output of about 60,000 tons of nitrogen. It took part in the extension of the plants of the Badische Anilin und Soda Fabrik at Oppau, the lime-nitrogen plants in Waldshut (the Lonza Works), at Knapsack (Aktiengesellschaft für Stickstoffdünger) and Margarethenberg (the Bayerischen Stickstoff Works).

The views of the parties concerned as to whether German agriculture will be in a position to absorb these great quantities of nitrogen are at variance. It is generally agreed that it will be possible to apply to German farms and fields triple the amount of nitrogen which they now receive and so to increase their yields that the importation of foreign food and foodstuffs will be unnecessary or at least limited to particularly high-value products, for it is generally assumed that in most cases this increased nitrogen application still lies below the limits of maximum action. Therefore with a complete fertilization one should count on an increase in yields of about 20 to 25 kg. vegetables (15 kg. straw), or 125 kg. potatoes, or about 150 kg. sugar beets, or 250 kg. fodder beets, per kilogram of applied nitrogen. It is not agreed as to whether the natural limitations of agriculture, the physical peculiarities of the soil, the water supply, the equipment, the efficiency of agricultural labor, will allow the increased production which would be expected from this increased application of nitrogen, for all of these factors either have undergone great depreciation during the war or have been wholly destroyed. In this difference of opinion the decision is of importance as to the beneficial action of nitrogen on the soil when there is a simultaneous impoverishment of phosphoric acid and as to whether there really is any phosphate impoverishment or not.

Pre-War Fertilizer Situation and Present Outlook

Before the war 200,000 tons of nitrogen and 600,000 tons of phosphoric acid were used each year, that is, one part of nitrogen was used to every three parts of phosphoric acid. It is frequently assumed that this relation must be adhered to in order to assure a continuous full fertility of the soil, because the phosphoric acid is utilized only to the extent of about 30 per cent. On the other hand, it is assumed by many of the authorities on this subject and by practical farmers that this ratio can be altered to about one part of nitrogen for every part of phosphoric acid without diminishing the activity of the nitrogen, since great quantities of phosphoric acid have been previously added to the soil and have not yet been used up. The resulting accumulation of phosphoric acid, in conjunction with the increased application of nitrogen and with other improvement of the soil, depending on circumstances, by means of gravel, lime or clay, should make possible a considerably increased utilization of the phosphoric acid. It should be remembered in this connection that plant material on the average contains only one part of phosphoric acid to two parts of nitrogen, so that if phosphoric acid were applied even in this ratio no impoverishment of the soil in the strict sense would occur.

In this conflict of opinion one thing can be taken as certain—namely, that under given conditions in the next few years very much greater quantities of nitrogen than before the war can be supplied with full effect, even if the possible maximum does not hold.

The situation as regards prices will be of the very greatest importance for the utilization of this increased amount of nitrogen; in the first place, because the cost of fertilizers in general, as a result of the inevitable increase in cost of phosphoric acid, will be greater than before the war; and also in view of foreign competition.

Importance of Foreign Competition

In fixing nitrogen by the Haber process coal, and by the Frank-Caro process coke, is required. The price of coke has advanced since the upheaval of the war by about 60, that of coal by about 50, and that of brown coal

*Translation from *Chemische Industrie*, Nos. 13 and 14, July, 1919, by Arthur B. Lamb.

by 9½ marks per ton. Wages, in spite of their already extreme high level, are still tending to rise.

How far the German nitrogen industry will be able to cope with foreign competition, in view of these high wages and high costs of combustibles, cannot at present be predicted. Since the cost of coal, which in the future is sure to be one of the most important items of expense, can hardly decrease, the lime-nitrogen industry, on account of its unusually small consumption of coke, will be in a very favorable situation. This will be particularly true when the construction market sinks to some halfway normal level so that the capital cost of water-power developments will be more reasonable. On the other hand, if this rise in the cost of coal continues, those lime-nitrogen plants which depend on steam power will surely be forced to transfer their carbide furnaces to places where water power is available.

Saltpeter, in addition to lime-nitrogen, is of considerable significance as regards foreign competition in fixed nitrogen. How far Chilean saltpeter can meet a reduction in price, and therefore come again into use here, depends largely on the price of coal and the level of wages in Germany. One should not overlook the fact that extensive improvements and economies in operation are possible in the Chilean saltpeter industry and that the development of the fixed-nitrogen industries in other lands will surely force the Chilean producers to undertake these improvements. Certainly the high freight rates and the small exchange value of the German mark outside of Germany will prevent the importation of saltpeter into Germany; but how long these circumstances will persist it is difficult to predict with certainty. Anyway, we must expect that if any further rise in the cost of coal or the level of wages in Germany occurs, competition with Chilean saltpeter is not out of the question.

Far more dangerous, however, at the present time, appears to be the possibility of competition with artificially fixed nitrogenous fertilizers produced in foreign countries.

American Competition

The fixed-nitrogen industry has undergone an extensive development in many foreign countries, chiefly through the construction of new lime-nitrogen plants. Almost without exception these plants are situated near sources of very cheap water power or of natural gas, and are therefore but slightly affected by the increase in cost of combustibles.

The largest of these plants is located in the United States, in Alabama. Its situation is most excellent. It is connected with the ocean by means of the Coosa River,[1] which has been made navigable. It is situated at a source of almost constant water power amounting to 400,000 horsepower, and is right in the midst of a locality where all the raw materials of the lime-nitrogen industry are present in the highest purity and at the very lowest prices. From the extensive deposits of bituminous coal the very best coke can be obtained, which cost during the war only about 75c. per ton.[2] For burning the very pure marble limestone, the otherwise unutilized gases from the coke ovens are available. Great quantities of copper-bearing pyrites furnish, on smelting, sulphur dioxide, which must be converted into sulphuric acid, but which at the present time is not used on the spot. Near by are inexhaustible deposits of high per cent phosphate rock. The possibility therefore exists of using the otherwise wasted sulphuric acid and phosphate to make phosphoric acid, and by neutralizing this with ammonia from lime-nitrogen, producing cheaply the so-called American "ammophos," or ammonium phosphate, containing roughly 45 per cent of water-soluble phosphoric acid and 20 per cent of nitrogen.

To be sure, the United States is in a position to use right there the nitrogen thus produced, amounting to about 130,000 tons per year; particularly as the plants are located in the midst of an extensive cotton-growing district. Nevertheless, a considerable extension of this project is contemplated and because of the high intrinsic value of the product (ammonium phosphate) it will be possible to ship it to long distances to places where its phosphoric acid content will be of importance, and hence it will be sure to offer very strong competition to the German fixed nitrogen industry.

Norwegian and Other Competitions

The economy with which nitrogen can be produced in the Norwegian lime-nitrogen plants is of a similar order, but the situation is perhaps not quite so favorable as in the above case. According to recent information the yearly production of these plants is between 100,000 and 130,000 tons of nitrogen. They, too, are located near cheap water power, and since they can utilize their product as return freight in ships bearing English coke, they are in a position to operate cheaply and to ship their output to great distances.

Published figures from other countries show that their output from lime-nitrogen per year is as follows:

	Tons Nitrogen		Tons Nitrogen
France	30,000	Bohemia	7,000
Spain	10,000	Lower Rhine	7,000
Italy	30,000	Japan	48,000
Dalmatia	24,000	Canada	40,000

So, as far as is known, about 450,000 tons of nitrogen can be produced as lime-nitrogen every year in foreign countries, while a further output of 500,000 tons per year will be provided by great plants already under construction. Moreover, the very great increase in the amount of ammonia secured in byproduct coke ovens in all countries where coal and coke are produced, particularly in the United States and in England, must be taken into consideration, so that an increase in the yearly output of fixed nitrogen from foreign countries amounting to 500,000 tons must be assumed.

Economic Outlook of the Nitrogen Industry

The total increase, then, in the yearly output of nitrogen in Germany and all foreign countries amounts to about 800,000 tons and is considerably greater than corresponds to the total output of Chilean saltpeter before the war (3,500,000 tons). This will surely affect the nitrogen market very decidedly, even if we can count with certainty on a very great increase of the nitrogen consumption in all countries. The competition of foreign countries is of even more consequence in considering the future German situation, when it is recalled that even in the year 1914, before the war, a combination of the saltpeter and lime-nitrogen producers of the whole world was proposed.

We can be very sure that faced by such circumstances the German industry will have no easy task in furnish-

[1] The author is in error regarding the location. The plant is at Muscle Shoals, on the Tennessee River.—Editor.

[2] This figure is evidently a mistake. As reported during the hearing before the House Committee on Military Affairs (Chem. & Met. Eng., vol. 21, No. 2, July 15, 1919, p. 67), the cost of coke at U. S. Nitrate Plant No. 2 was $6 per ton.—Editor.

ing an adequate supply of this material to German agriculture at *cheap* prices. The government, therefore, as soon as it had begun to take an interest in the nitrogen situation, was busied with arrangements to consolidate the German nitrogen industry, so that it might fulfill its function satisfactorily and be resistant to outside attack.

Establishment of the Nitrogen Traffic Monopoly

For this purpose in 1915 the government brought forward legislation permitting the establishment of a nitrogen traffic monopoly. The purpose of this proposal as appeared from the discussion was not so much the introduction of a traffic monopoly itself as the establishment of a close organization of the industry and the assurance to agriculture of suitable, and, indeed, extremely cheap prices for nitrogen (namely, 70 pfennigs per kilogram of nitrogen in lime-nitrogen). The proposal was not rejected, but also it was not adopted. It remained unacted on in the Commission.

Meanwhile, a further increase in the nitrogen industry of about 200,000 tons per year has taken place. The whole situation has altered and the production costs of all the processes have undergone a complete re-alignment. Certain efforts by the government have resulted in the establishment of an autonomous combination within the industry. On May 8, after the Finance Commission of the National Assembly had granted permission, the Nitrogen Syndicate, in co-operation with the government, was established as a limited company (Gesellschaft mit beschrankter Haftung) which included the whole nitrogen-producing industry, as well as other industries related to it. The incorporators of this undertaking, which has a nominal capital of 241,800 marks, are as follows:

	Shares in Marks
1. Badische Anilin und Soda Fabrik	150,000
2. The lime-nitrogen firms	41,800
3. The German Ammonia Sales Co., together with its affiliated organizations of the Oberschlesian Coke Works and the Union of German Gas Works	50,000
Total capital	241,800

The allotment of production is as follows:

	Tons Nitrogen
1. The Badische Anilin und Soda Fabrik up to	300,000
2. The lime-nitrogen industry up to	93,000
3. The byproduct industries up to	120,000
Total	513,000

The government, and each of the three incorporations, have the right to name one member of the four-membered board of directors.

The government has retained for itself the far-reaching right for the conduct of the business, and particularly for the allocation of the product, and the fixing of prices. The board of managers of the company is to consist of ten persons, who will be intrusted with most of the control of the business. The government, the Badische Anilin und Soda Fabrik and the byproducts industries will elect three members each of this board, and the lime-nitrogen industry one member. Each group will further appoint alternates equal in number to its members. The chairman of the board, as the foremost director of the business, will be selected by the government, and the vice-chairman from the three members named by the Badische Anilin und Soda Fabrik. The function of the board of directors is an honorary one. The chairman, as business director, only will be paid. Decision as to sales, prices, etc., will require approval of the government representative. As a fundamental basis, the price of nitrogen in lime-nitrogen, ammonium sulphate and saltpeter has been fixed in ratio of 8 : 9 : 10.

The sale of the output depending on the demand will take place according to the deserts of the single products. Every output will be computed on its own basis and all the plants will receive for every product the prevailing average price. Exportation can take place only after all domestic demands have been met.

How the distribution will be carried through in detail has not yet been decided, but it will be carried out on a basis of the already existing organizations of agriculture and of legitimate trade. For this purpose, at the instigation of the Finance Ministry, a joint body consisting of the producers and consumers was established, called its Nitrogen Commission, to which the determination of the prices, conditions of delivery, etc., were intrusted. The Commission consists of twenty-two members. The Nitrogen Syndicate, the government and agriculture name five each, the fertilizer manufacturers and the fertilizer dealers each elect one. Three members are appointed by the Associated States and one each by the Labor Bureaus of Industry and Agriculture.

Future Developments of the Organization a Matter of Conjecture

The organization thus fixed upon gives each of the industries concerned and any new industries the possibility of far-reaching development, and on the other hand, at the same time permits the government, by the control of all distribution, exportation and prices, to safeguard the social and financial interests intrusted to it, as had been demanded by the National Assembly. It makes possible the distribution of nitrogen in a more rational manner than has previously been the case, since, by a centralized control of distribution, transportation and storage facilities are utilized in the most efficient manner possible.

By the establishment of the Nitrogen Snydicate and of the Nitrogen Commission an important step has been taken to assure the success of the German chemical and agricultural industries. How far the Nitrogen Syndicate can also be looked upon as a money-making enterprise will depend on future developments, particularly on how large production costs will prove to be. The government takes a leading part in this production and therefore is in a position to judge regarding all the factors which come into play and to influence them. For the present it will maintain the existing standards of maximum prices and assessments (in agreement with the requirements of the National Food Ministry of March 13, 1919) until a clearer insight can be had into production and importation situations.

Exposition of United States Manufacturers in Buenos Aires

Twenty-two countries are holding foreign trade fairs during 1920, and of these France schedules eight, Germany twelve, Great Britain nine and Italy four. Among others of interest to manufacturers in the United States is the National Exposition of U. S. Manufacturers to be held at Buenos Aires in October. It is to be arranged and managed by the American National Exposition, Inc., of New York, G. Hough Perry, director.

Classification and Salaries for Chemists

Report of the Congressional Commission on Reclassification of Government Salaries, Outlining the Qualifications, Principal Lines of Promotion and Compensations for Government-Employed Chemists

By R. S. McBRIDE

THE report of the Congressional Commission on Reclassification of Government Salaries, presented recently, gives us the first systematic classification which has ever been made in the varieties and grades of technical positions which are encountered in our complicated professional life. This classification has a very large interest to executives and employing chemists, for it gives a clean-cut basis upon which they can judge the relative responsibility which should be intrusted to men of different grades in technical and scientific work. The relative responsibility for planning and execution of research and for the conduct of executive work in a chemical organization is particularly important, as in many cases there is very little understanding of the degree of experience really required for executive work in different places.

The classification of chemists which is proposed divides workers in this science into two major groups—those in the sub-professional grades, who are called junior aid or senior aid in chemistry, and the group which includes those who are graduated from a collegiate course specializing in chemistry, who are called junior chemist, assistant chemist, associate chemist, chemist, or senior chemist, according to the exent of their experience. A very similar classification using the same titles and the same general qualifications and duties was adopted by the commission for all the other engineering and scientific services of the Government. In other words, the commission has recognized the same principles to govern in all of these professional fields. The definite statements of the commission with respect to these various classes in chemistry are as follows:

Junior Aid in Chemistry

Duties: To assist chemists in the performance of routine laboratory work; and to perform related work as required.

Qualifications: Training equivalent to that represented by graduation from high school, including one year of chemistry and one year of physics; accuracy and carefulness.

Principal Lines of Promotion: To, senior aid in chemistry.

Compensation for Class: $840-$900-$960-$1,020-$1,080-$1,140-$1,200 per year.

Senior Aid in Chemistry

Duties: To assist chemists in the performance of chemical work, or to make routine chemical analyses; and to perform related work as required.

Qualifications: Training equivalent to that represented by graduation from high school, and by not less than two years' college work, including at least fifteen college credits in chemistry; accuracy and carefulness.

Principal Lines of Promotion: From, junior aid in chemistry. To, junior chemist, junior metallurgist.

Compensation for Class: $1,200-$1,320-$1,440-$1,560-$1,680-$1,800 per year.

Junior Chemist

Duties: To perform, under immediate supervision, routine work in chemistry; and to perform related work as required.

Qualifications: Training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in chemistry, including general inorganic, analytical, and organic chemistry; additional training in one or more of the following optional lines; biological, dairy, engineering, explosives, food, fuel, inorganic, metallurgical, organic, petroleum, pharmaceutical, physical, or soil chemistry; ability to read scientific French or German; and initiative.

Principal Lines of Promotion: From, senior aid in chemistry. To, assistant chemist.

Compensation for Class: $1,800-$1,920-$2,040,-$2,160 per year.

Assistant Chemist

Duties: To perform, under supervision, either individually or with the assistance of subordinates, general work in chemistry; and to perform related work as required.

Qualifications: Training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in chemistry, including general inorganic, analytical, and organic chemistry, and by not less than two years' graduate work in one or more of the following optional lines: Agricultural, analytical, biological, dairy, engineering, explosives, food, fuel, inorganic, metallurgical, organic, petroleum, pharmaceutical, physical, or soil chemistry; ability to read scientific French and German, and to prepare chemical manuscripts in clear and concise English; and initiative.

Principal Lines of Promotion: From, junior chemist. To, associate chemist.

Compensation for Class: $2,400-$2,520-$2,640-$2,760-$2,880-$3,000 per year.

Associate Chemist

Duties: To perform, under general direction, either individually or with associates or subordinates, specialized work in chemistry which may or may not involve supervisory duties; and to perform related work as required.

Qualifications: Training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in chemistry,

including general inorganic, analytical and organic chemistry, by not less than three years' graduate work, and by one year's professional experience, in one or more of the following optional lines: Agricultural, analytical, biological, dairy, engineering, explosives, food, fuel, inorganic, metallurgical, organic, petroleum, pharmaceutical, physical, or soil chemistry; ability to read scientific French and German, and to prepare for publication, in clear and concise English, manuscripts embodying the results of chemical investigations; and proved technical and scientific proficiency.

Principal Lines of Promotion: From, assistant chemist. To, chemist.

Compensation for Class: $3,240-$3,360-$3,480-$3,600-$3,720-$3,840 per year.

Chemist

Duties: To perform one or more of the following functions: (1) to carry on, either individually or with associates or subordinates, highly specialized lines of chemical research; (2) to act in a consulting or advisory capacity on problems in chemistry; (3) to plan and execute major lines of chemical work; or (4) to perform major administrative work under executive director; and to perform other related work.

Qualifications: Training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in chemistry, by not less than three years' graduate work in chemistry, and by not less than four years' professional experience, of which at least three years shall have been in work of the grade required of an associate chemist; proven ability to carry on or to direct research work in chemistry; ability to read scientific French and German, and to prepare for publication in clear and concise English, manuscripts embodying the results of chemical investigations.

Principal Lines of Promotion: From, associate chemist. To, senior chemist; assistant chief, Bureau of Chemistry; chief, Bureau of Chemistry.

Compensation for Class: $4,140-$4,320-$4,500-$4,680-$4,860-$5,040 per year.

Senior Chemist

Duties: To perform one or more of the following functions: (1) to carry on or direct the most difficult and comprehensive lines of advanced chemical investigations; (2) to act as consulting specialist in the field of chemistry; or (3) to perform major administrative work involving the broadest lines of policy; and to perform other related work.

Qualifications: Training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in chemistry, by not less than three years' graduate work in chemistry, and by not less than eight years' professional experience, of which at least three years shall have been in work of the grade of chemist; large capacity and proved ability to perform, direct, or administer work in the most difficult and comprehensive lines of chemistry.

Principal Lines of Promotion: From, chemist. To, assistant chief, Bureau of Chemistry; chief, Bureau of Chemistry.

Compensation for Class: (Not specified).

Assistant Chief, Bureau of Chemistry

Duties: To assist the chief in the administration of the work of the Bureau of Chemistry, including the supervision of its field force, inspectional, and clerical personnel, and in the enforcement of the food and drugs act; to act as chief in his absence; or, to assist the chief in the administration of the research work, scientific personnel, and related work of the Bureau of Chemistry; and to perform other related work.

Qualifications: Either (1) training equivalent to that represented by graduation with a degree from an institution of recognized standing; preferably professional legal training in addition; extended executive experience; not less than five years' experience in the administration of the food and drugs act; judicial temperament and exceptional executive capacity; or (2) training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in chemistry and related subjects, and by not less than three years' graduate work in chemistry; extended experience in conducting and administering research work in chemistry; large capacity and good judgment of men.

Principal Lines of Promotion: From, chief of district; senior chemist; chemist. To, chief, Bureau of Chemistry.

Chief, Bureau of Chemistry

Duties: Under the general direction of the Secretary of Agriculture, to have administrative charge of all the activities of the Bureau of Chemistry; to be responsible for its expenditures and the efficiency of its employees; to administer the work required in the enforcement of the food and drugs act; to initiate and direct research in agricultural, food, drug, and industrial chemistry, as well as in the field of pure chemis-

SALARIES RECOMMENDED FOR CHEMISTS AND ENGINEERS

	Qualifications for Chemists	Salaries Recommended by Chemists Committee	Salaries Recommended by Engineering Council Committee (for Engs.)	Salaries for Chemists and Engineers Recommended by Classification Commission
Junior aid	High school graduate	$1,200–1,560	$1,080–1,560	$ 840–1,200
Senior aid	Two years' college work	1,680–2,400	1,680–2,400	1,200–1,800
Junior chemist	College graduate major in chemistry	1,800–2,760	1,620–2,580	1,800–2,160
Assistant chemist	Two years' post-graduate work *	3,000–3,960	2,700–4,140	2,400–3,000
Associate chemist	Three years' post-graduate *, and one year's professional experience	4,320–5,760	4,320–5,760	3,240–3,840
Chemist	Three years' post-graduate work *, and four years' professional experience, of which three years must be in responsible position	6,000–9,000	5,940–7,860	4,140–5,040
Senior chemist	Three years' post-graduate work *, and eight years' professional experience, of which three years must be in work of chemist grade	10,000–25,000	8,100 and up	No recommendation

* One and one-half years' practical experience judged equivalent of one year of post-graduate work.

try; to consider and take action on questions concerning chemistry and related subjects referred by the Secretary; and to perform other related work.

Qualifications: Training equivalent to that represented by graduation with a degree from an institution of recognized standing, with major work in science, and by not less than three years' graduate work in chemistry; extended experience in the application of scientific methods of research to the solution of problems in chemistry and related subjects; not less than five years' responsible administrative experience; ability to determine productive lines of research relating to chemistry, and to organize and direct staffs of investigators and regulatory workers.

Principal Lines of Promotion: From, assistant chief, Bureau of Chemistry; senior chemist; chemist.

Experience Required

It should be noted in this series of statements regarding qualifications that emphasis has been laid by the commission upon post-graduate experience in college work. This conclusion is in accordance with the recommendation which was made to it by the committee of chemists of the Government service selected to advise the commission regarding the needs in this field. This committee urged that a distinction be made between the scientific and the technical services in this particular. An engineer typically gains his advanced work in practical, field or plant experience and he advances most rapidly in his profession under these circumstances, in the opinion of those who were advising the commission. On the other hand, the chemist who goes into some laboratory or plant without the broadening influence of post-graduate work is apt to become highly specialized, or narrow in his conception of research and development methods. It is believed, therefore, that post-graduate training is more valuable for a chemist than a corresponding length of time in practical work. However, it was recognized by this committee of chemists, and so recommended to the commission, that three years of practical experience be regarded as equivalent to two years of post-graduate college work. This relationship should be borne in mind when contrasting the qualifications specified for chemists and for engineers.

Salary Recommendations

The Classification Commission had to guide it a large amount of information which had been gathered by the experts sent out to interview persons in the industries, representing altogether in this field many hundred positions for which data were available. The commission also had the report of the committee on classification and compensation of engineers, presented by the representatives of Engineering Council. To supplement these, the committee of Government chemists appointed to advise the commission regarding the chemical services drafted certain recommendations, discussed these in various ways with the chemists within and without the Government service and formulated certain recommendations as to salary schedules. These various recommendations are tabulated and charted to show the contrast.

It will be noted that the recommendations of the chemists are much higher than those which were recommended by Engineering Council's committee. However, there was considerable justification for this, since the data gathered by the chemical investigators of the commission showed that chemists were in general receiving materially higher salaries than engineers of corresponding experience. In explanation of this rather surprising statement, it should be borne in mind that the demand for chemists has increased very rapidly during recent years and the supply has probably not correspondingly increased. It has been inevitable, therefore, that chemical salaries should advance more rapidly than salaries in the engineering field, probably more nearly keeping pace with the increasing costs of living than the salaries of most any other group of technical or scientific workers.

In making the recommendations to the commission regarding salary, the chemists did not anticipate that the salaries recommended could actually be granted immediately, but despite this fact they felt it necessary to set forth a schedule of salaries which could be considered reasonably adequate to meet the competition of the industries for the services of chemists well trained in various fields. In the judgment of this committee, the schedule suggested represents the compensation which any employer of chemists must pay at the

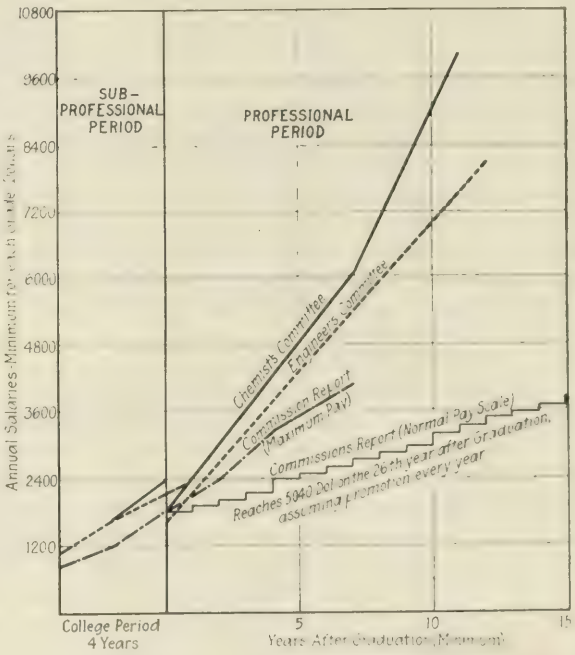

CHART SHOWING SALARIES OF GOVERNMENT CHEMISTS

present time if he is to secure the services of men equal to or above average ability in the different grades. Undoubtedly, many men can be secured at lower rates, but the qualifications or ability would, it is believed, be correspondingly less.

Initial Salary for Government-Employed Junior Chemists as an Inducement for Beginners

In reference to the salary schedule recommended by the committee of chemists, another point should be mentioned, namely, the beginning salary for junior chemists, which was fixed at $1,800, both in the recommendations to the commission and in the commission's recommendations to Congress. This is recognized by all concerned as being a figure slightly above that usually paid in the industries for men just graduated from college in chemical courses. It was believed by the committee that $1,500 per annum would represent more

nearly the beginning salary in industrial work of this sort, but a man going into the industries is usually advanced very rapidly, generally once or twice within the first year of service, if he is really making good. In the Government service such rapid advance is not at all feasible and therefore, in order to attract some of the best available talent from the young graduates, an initial salary slightly greater than that paid by the industries is found essential. Even with this slightly greater starting salary, it is believed that the men in the industries will within a year or two be receiving substantially as much or perhaps a trifle more than those in the Government service, even if the committee's recommendations were adopted.

Promotions

One of the difficult problems in any scientific organization is the question of how often the younger members of the staff should be promoted. In the judgment of the commission, and according to its recommendations to Congress, members of the Government scientific services should be promoted more or less automatically every year, if they are satisfactorily filling their positions. However, these promotions would continue only within the salary range of a single class. For example, a man might be advanced from the initial salary of $1,800 proposed for junior chemists by $120 a year under normal circumstances for three successive years, thus reaching $2,160 per year even though he was just an ordinarily successful man in this grade. To advance from the highest salary in the junior chemists' grade to the lowest salary in the assistant chemists' grade, however, would require a special action of some sort, since it is deemed to be not a normal increase in salary to go from a position of one title to a position of higher title.

It is realized, of course, that these automatic promotions are not sufficient for special cases of unusual merit or ability. Therefore it is anticipated that double promotions would be given to some of the better men and that some men who really were not making good, but who were sufficiently valuable to make it unnecessary to discharge them, would probably not be given any advances at all, even within the grade. However, the thought seems to have been throughout that a normal increase of the size indicated would come more or less regularly each year to most of those within that grade.

General Status

The bulk of the commission's salary material and much of the data presented to them by various agencies has not yet been made public, but will undoubtedly be brought out in the course of any action which the Congressional committees may take upon this report.

In general, the report of the Classification Commission has been very favorably received by the scientific and technical people of Washington, who think the system of classification proposed is excellent and that the general provisions are quite satisfactory. However, the salary schedules recommended for the middle and upper grades are very frequently criticized as being wholly inadequate to hold the technical men required for proper development of the Government service. It is to be expected, therefore, that considerable debate on these points will be developed during any further Congressional action.

Low-Temperature Carbonization of Coal in England

THE coal output of the United Kingdom in 1913 was estimated at 280,000,000 tons, valued at $973,300,000. Between 40,000,000 and 50,000,000 tons is devoted to domestic consumption, and if this amount were converted into smokeless fuel by low-temperature carbonization, some 640,000,000 gal. of fuel oil would be obtained annually. If this system were applied to all coal consumed in the United Kingdom, the quantity of by-products recorded would be enormous.

A recently organized British company is manufacturing a smokeless fuel known as coalite, which is claimed to be a natural briquet, generating as much heat per unit as coal. The volatile constituents of the coal are collected by a process of low-temperature carbonization, recent experiments establishing the following products obtained at one time from one ton of bituminous coal:

(*a*) Three gallons of motor spirit—nearly double the usual yield of motor spirit from processes where coal is distilled at a high temperature. This spirit is refined, and suitable for motor cars, aëro engines, tractors, and every purpose for which petrol (gasoline) or benzol is used today.

(*b*) Sixteen gallons of oils for burning, lighting, and lubricating. This oil is similar to crude petroleum. It can be burned without refining, direct under boilers for naval and maritime purposes generally. If distilled the products obtained are even more valuable and find a ready market for many purposes. The crude oil may be separated into motor spirit, cresylic oils, burning oils for lamps, lubricating oils, oils for Diesel engines, and pitch of superior quality for insulating and other purposes.

(*c*) Seven thousand cubic feet of gas. This gas is of higher quality than that made by gas works and is of great value for lighting, heating, and power purposes. Its heat value is 600 B.t.u. per cubic foot, after removal of the light oils, whereas that of ordinary coal gas, similarly treated, is about 500 B.t.u.

(*d*) Twenty pounds of sulphate of ammonia, for fertilizers and high explosives.

(*e*) Fourteen hundredweight of smokeless fuel.

The question of coal reserves and consumption is receiving a great deal of attention and is bound up with such problems as the generation of electricity by central power stations where coal can be economically consumed with due reference to the salvage of valuable by-products, as well as the provision of smokeless fuel for household use, the provision of motor spirit capable of replacing gasoline, and the supply of fuel oil for naval and mercantile use.

At a recent meeting of the British Association for the Advancement of Science, Sir Dugald Clark stated that if the average figure of 5 lb. of coal per horsepower be reduced to 1½ lb. or less, the industrial civilization of the United Kingdom would be prolonged from 500 to 1,000 years. At the 1913 rate of consumption the coal reserves of the United Kingdom will be exhausted in 500 years, and there is every prospect of increased consumption unless more economical measures are adopted. Therefore as a matter of national economy and conservation of natural resources the burning of bituminous coal in open hearths and furnaces is being deprecated for extravagance no less than in abatement of the dirt, dust, and smoke nuisance.

Peat as a Possible Source of Industrial Power*

Extent and Formation of Peat Deposits—Mechanical Preparation of the Peat Previous to Its Use as Fuel for Steam Raising or in a Gas Producer and the Economic Factors Involved in Its Competing With Coal—Peat as a Source of Ammonia Fertilizer

By HERBERT PHILIPP

THE use of peat as a source of heat goes back beyond the historical period into the ancient history of the early tribes in northern Germany. Pliny, the Roman naturalist, gives us possibly the first indication of the use of peat. He reports that the Teutons on the border of the North Sea dried and burned mud, what we now would call peat. In Ireland, Great Britain, Russia, Scandinavia, Germany, Holland and parts of France peat has been used as a fuel since time immemorial. The peat was cut from the bog very much in the same manner as it is still being done in many parts of Europe, where it is cut in brick shapes, allowed to dry in the wind and sun and stacked up, similarly as the American farmer piles his cord wood.

It is only in the last seventy years that any progress has developed in this industry, and although very little has been done in this country to obtain efficient results in using peat as a source of power, much can be expected in the near future of making this resource valuable and an economic factor in our industrial life.

Extent and Formation of Peat Deposits

Peat is disintegrated vegetable matter accumulated in areas of poor drainage where the chemical decomposition has been partly retarded according to a variety of conditions. Some of the conditions have resulted in complete decay, so that the original substances have disappeared, while others have simply resulted in the loss of more easily changed compounds and gaseous elements, the material retaining its original form and mechanical structure. The deposits of peat are not uniformly distributed over our country, but occur in practically every state east of the Dakotas and north of the Carolinas to the Canadian border. This is supplemented by deposits all along the Atlantic coast, the state of Florida and across Texas to the Mexican border. In the Pacific coast states are some areas of peat deposits, especially in California and in the valleys of some of the lakes and rivers of Oregon and Washington. It is estimated that there are approximately 12,000 square miles of peat deposits in the United States of an average depth of 9 ft. which would represent a total of about 14,000,000,000 tons of fuel, provided the whole were converted into peat fuel, which is no small resource and represents a possible means of furnishing heat and power for a considerable number of years.

It is only in recent years that peat has become of enough interest in this country to endeavor to classify the various kinds which are made. This work is being undertaken by Dr. Alfred P. Dachnowski of the U. S. Bureau of Plant Industry, and his initial attempt represents an admirable contribution to our peat literature. The terms muck, humus, moor, marsh (fen), bog, heath and swamp are terms used without any definite relation to the stage of development of the peat in the deposit. These terms usually relate to the marked physiognomy of vegetation appearing on the deposit. A peat deposit can be defined as a compact accumulation of plant remains of at least 8 to 10 in. (20 to 25 cm.) in thickness. No deposit containing more than 40 per cent of mineral matter must be included in this definition. Peat deposits usually occur upon gentle slopes, flat areas, in shallow depressions on the earth's surface which have neither drainage or are poorly drained so that the surface is always wet or covered by water.

Owing to the various conditions under which peat deposits have been formed and to the various types of vegetable matter composing them and also to the various locations and climatic changes to which they have been exposed, each deposit is practically a study in itself. There are possibly no two deposits that are exactly alike, although a large number may be very similar in composition. This explains one of the reasons why difficulties have been met with in trying to work one deposit by means adapted on another deposit. Even great variations can be noted in deposits which are only a few miles separated.

Growth of Peat Industry

A peat industry exists in this country, and has grown steadily the last twelve years till it now represents a real industry. However, only a small quantity of peat up to the present time has been manufactured for fuel purposes, the largest amounts being used in agriculture and in the fertilizer industry. The statistics in the table show the amount of peat produced and also the quantity used for fuel purposes.

CRUDE AIR-DRIED PEAT AND PEAT FUEL PRODUCED IN THE UNITED STATES, 1908-1918

Year	Total Peat Produced Short Tons	Total Peat Fuel Used Short Tons
1908	24,800	900
1909	29,167	1,145
1910	37,024	...
1911	55,143	300
1912	47,093	1,300
1913	33,260	...
1914	47,093	1,925
1915	42,284	...
1916	52,506	...
1917	97,363	...
1918	151,521	20,567

It will be noted that during the last few years the production of peat has practically trebled due to the extensive application of this material in fertilizers. It will be well to mention here that peat in this country is generally comparatively rich in nitrogen, and that is the reason why the use of peat in agriculture is proportionately greater in the United States. The peat fuel production was negligible until 1918, when the high price of coal gave quite an impetus to this indus-

*Read before the New York Section of the American Electrochemical Society, Feb. 27, 1920.

try, and the future offers very promising developments for a successful peat fuel industry in this country.

In Europe practically all the peat which is excavated is used for fuel purposes. Since coal has become high in price and as far as we can determine will remain so, peat becomes an economic factor in our future industrial progress.

Many Failures to Produce Peat Economically

A large number of attempts have been made in the past to produce peat fuel economically, but the majority have proved uncommercial and we cannot speak of any successful peat fuel undertakings before 1918. The large number of failures were due to many factors, which were, chiefly, lack of capital, poor engineering, difficulties of distribution, prejudice, stock jobbing, and competition of low price coal. From this it will be seen that too many efforts have been made with small capital and poor engineering ability to allow the industry to get on its feet, and that has for years given the industry a bad reputation and prevented any attempts being made on a big scale and has generally created ridicule in suggesting a development of a peat fuel industry. With the present high price of fuel and the inability to obtain a steady supply, a peat fuel industry is now looked upon as a remunerative possibility.

There is more than one way of utilizing peat for the production of industrial power, yet whatever method is used the peat must first be excavated from the deposit, and the economic excavation of peat has been the biggest bugbear in the peat industry.

Operation Feasible Only in Dry Season

The average peat deposit contains from 80 to 90 per cent water, and that must be economically driven off to make the peat available as fuel. It will therefore be easily realized that for every ton of raw peat excavated there is only 100 to 400 lb. of theoretically dry peat available. Peat deposits vary, and according to the grade of decomposition they will dry in the air at various rates. The more highly a peat is decomposed the quicker it will allow the moisture to evaporate and the more fibrous the material is the slower it will evaporate. This phenomenon is due to the fact that the moisture present is not all there as absorbed moisture, but the water present is in the cells of the vegetable mass. It is therefore necessary in most cases to pass the peat through a pugging or macerating mill.

Dependence on Local Climatic Conditions

In order to obtain a cheap fuel it can be inferred that peat cannot afford to be handled very much, and therefore the largest part of the drying has to take place on or near the deposit. It is manifestly unfeasible to use any artificial heat for producing peat fuel. However, there are conditions where waste heat can be used to advantage to reduce the moisture content of peat, as will be shown later. There is no cheaper method of drying than by nature herself, and the sun and wind have to accomplish the largest part of the drying in any development of a peat fuel plant. This shows how dependent the industry is on local climatic conditions—not only on the total hours of sunshine, but also on the winds and humidity of the atmosphere. Further the temperatures of the season play a big factor in the excavation and drying of peat; it is impossible to excavate peat when the ground is frozen. In other words, enough material has to be excavated in the good season of the year to supply a plant for the whole twelve months, and this is the point that so many plants have failed to realize, so that they have been forced to shut down for lack of material. The length of time that excavation work can take place varies with the location of each deposit and due regard must be taken of the climate of the locality.

Mechanical Excavating and Handling Apparatus

In most countries the peat is commonly used as fuel and the hand digging of peat is still used. The mechanical handling of peat, which originated in Germany, is only being taken up by deposits where large amounts of peat have to be excavated. Where peat is used as an industrial fuel, only mechanical excavating and handling apparatus can be considered. There are two possibilities of opening up a peat fuel deposit or peat bog; namely, the operation of excavating a dry peat bog and the excavation of peat from an undrained swamp.

In the first case that part of the deposit which is to be used is drained, generally by preparing small ditches which lead into a main ditch. The deposit is then cleared and leveled so that the surface can be used as a drying ground. These ditches should not be too deep and should not go beyond the depth of the deposit to prevent in the latter case contamination with mineral substances. It is often necessary during the winter season to allow the water to accumulate in the deposit and in case the deposit takes fire it can be quenched by allowing the water to rise in the ditches.

The machines used for excavating the peat are generally of the simplest form of construction and are similar to those used ordinarily in ditching and digging. The modern tendency in using power ditching machines corresponds to the types of side chain and bucket excavators, which are very effective in peat which is well decomposed, but cause trouble in poorly decomposed deposits on account of tree stumps which have not yet disintegrated. These machines generally work from the side of the ditch, which has the advantage of mixing the peat from the different depths and thereby securing a homogeneous product. On account of the high cost of labor in this country the peat excavated, even in small plants, is found to be done more economically by machines than by hand digging. The steam shovel has also been used in this country and gives satisfactory results. On account of producing homogeneous material and the ability to spread the material easier on the drying ground, the chain and bucket excavator seems to be most favored.

Difficulties to Be Overcome

In devising machines of this nature not only has the ability of excavating efficiently to be taken into consideration but also the expense and labor incurred in handling the material after it leaves the excavating machine. As peat deposits will not hold a very great weight per square foot, thought has to be given to properly mount the machine so that the weight is distributed as uniformly as possible. The machines are generally mounted on cars having wheels with very wide treads, which have on some deposits, even then, to be supplemented by timbers. The more modern machines are provided with caterpillar tractors, which have proved very satisfactory in this kind of work. Where possible these machines are operated by elec-

tricity, otherwise the power plant has to be installed on the machine. However, this should be obviated as far as possible on account of the possibilities of setting fire to the deposit during the dry season. Peat fires can become very disastrous and are often very hard to put out.

No Standard Peat Digging Machines

There are no standard peat digging machines in this country, and generally in each case they have to be designed to meet the local conditions. These machines have to be of an efficient form and provided with a hopper for receiving the peat which falls into a cutting or macerating trough, thus pulping the peat and cutting up its strands. These macerating machines are provided with screw conveyors and on the same shaft can have knives for cutting up the fibers, while other machines have sections provided with both fixed and movable knives which work together like the blades of scissors.

After the peat has passed through the above-mentioned machinery, it is then spread on the drying grounds, which is generally the surface of the deposit, and here exposed to the sun and wind. Every once in a while a new surface of this layer is exposed and eventually the material is scraped together and hauled to the plant. By this method peat originally containing 80 to 95 per cent water can be dried down to 25 to 35 per cent water right on the field, and this moisture content is low enough where peat is used in gas producers, but for cases where it is used for making steam direct it should be dried down to about 15 per cent water, although 20 per cent is frequently used; in a large power plant this can generally be accomplished at the plant, where enough waste heat exists to reduce the moisture content economically.

In excavating an undrained deposit the machinery has to be mounted on a barge or float and either a dipper-dredge or pumping system is used. Both of these systems are satisfactory; their use depends entirely on the local conditions, quantity of peat to be handled and its stage of decomposition. In each case, however, the peat has to be handled on drying grounds after it leaves these excavating machines. Highly decomposed peat can be very efficiently handled by pumping if very little fibrous matter is present in the deposit.

Costs and Methods of Burning Peat

The cost of excavating and air drying peat governs the success or failure of a peat fuel plant. All the cost involved in handling the peat from the deposit to its storage pile should not exceed $1.30 per ton of theoretically dry peat. The cost depends very much on the size of the excavation plant and on the climatic conditions. My experience in excavating peat covers a cost ranging between 25c to $1.30 per ton of theoretically air-dried peat on the field. It is seldom that the excavation price exceeds $1 per ton of peat, the average being in the neighborhood of 75c. per ton of theoretically dried peat.

In producing power from peat we have available the same methods as are now used for coal, either firing peat direct under a boiler for raising steam or gasifying it in gas producers and using the gas in gas engines or under boilers and in furnaces. Where industrial power is produced from peat, it is necessary to locate the power plant at the edge of the deposit or in very close proximity thereto. The reason for this is that the handling of large quantities of peat fuel involves several problems of a serious nature; on account of its bulkiness and low heating value, compared to coal, it necessitates handling larger volumes and burning an appreciably larger quantity than is the case when coal of a good quality is used for raising steam. Furthermore, very large stocks of peat fuel have to be held, and the sensible heat contained in the flue gases, together with exhaust steam, is used to advantage in reducing the moisture content of the air-dried peat. Peat fuel generally burns freely to a fine easily handled ash. Thus it is practically totally combusted and the handling of the ash is reduced to a minimum.

Analysis of Good Peat Fuel

An approximate average analysis of a good peat fuel is as follows:

	Per Cent
Volatile matter	60
Fixed carbon	30
Ash	8
B.t.u., 8,500	

When peat fuel is burned direct on a grate it is necessary that not too much fine material is mixed in the lumps and it is therefore frequently advisable to briquet the peat before using it for such purpose. Many peats have enough binding material present in them and others will not hold together at all unless mixed with pitch or similar material. In making machined peat it is advisable to form the bricks while the peat is still plastic and then let them dry. Some peat briquets form easily without the addition of any foreign binder, especially when heated up to about 100 deg. C., when the natural paraffine present will hold the peat in its form and produce briquets which are comparatively easy to handle.

Requisites of Boiler for Using Peat Fuel

The points to be considered in constructing a boiler for using peat fuel are a large grate area with very small air spaces, large combustion chamber, and long travel for the flue gases; 15 lb. of peat per sq.ft. of grate per hr. has been found good in practice. Peat has a disadvantage in allowing unburned hydrocarbons and hydrogen to escape in the ordinary combustion chamber built for burning coal. It is therefore necessary to have a specially constructed combustion chamber to insure complete combustion when using this fuel. Peat has another disadvantage, because when firing with peat the fire door has to be open quite a considerable part of the time, because men cannot handle as much peat on a shovel as coal owing to its low specific gravity. However, if the peat is used as a pulverized fuel it will be found not only economical to prepare but can compete with coal more advantageously.

When peat is dried, even air dried, it does not absorb moisture from the atmosphere very readily, and even with 20 to 25 per cent moisture content it has the physical characteristics of a dried material. Provided it has been properly macerated it is very easy to pulverize and will not pack, running and behaving similarly to dried sand. With these conditions, together with its low specific gravity and high combustibility, it makes an ideal powdered fuel. Peat has been used in this way in Sweden and has shown that it is possible to obtain better calorific value than by burning the peat on a grate, and every indication points to the fact that peat fuel can be used practically and commercially for

raising steam when used as a powder, so the future developments of the use of peat as an industrial steam raiser will tend to be in this direction.

Cost at Which Peat Can Compete With Coal

The maximum cost per ton which peat fuel can stand and still compete with coal is governed by the cost of steam coal at the place where the power plant is located. There is, however, a fixed minimum cost, determined by the cost of its manufacture, below which peat fuel cannot compete with coal. Peat used directly under a boiler for raising steam can generally compete with good steam coal costing $4.50 or less per ton or $4 or less per ton when the peat is used in a pulverized condition. Above this price where peat deposits which are suitable for fuel are available, they become a serious competitor of coal. The more economical method to convert peat fuel into power is to burn the same in a producer to form combustible gases and then use gas engines or burn the gas under boilers to obtain the desired results.

Inasmuch as peat used for generating steam contains generally from 16 to 21 per cent moisture, less water is evaporated than would be the case if peat were theoretically dried. Peat of this nature directly on the grate will evaporate on an average 4 lb. of water per lb. of peat, while pulverized peat evaporates about 5.25 lb. of water per lb. of peat powder.

Peat Producer Gas

The most economical method for producing power from peat is to convert the peat into combustible gases in a specially constructed gas producer, or if the gas contains any nitrogen to burn the same in a byproduct recovery producer. Since several of the peats examined in this country have a high nitrogen content, it would be possible to recover the largest part of this nitrogen in the form of ammonia.

The commercial use of peat in gas producers seems to have been successful in Germany and Sweden, where they have been used for several years in metallurgical operations, brick and glass making and in lime burning. Tests have been made on this continent both in Canada and at the fuel-testing stations of our Government, where it has been shown that gas of good calorific quality can be produced, similar results being obtained as in producer gas from bituminous coal. About 40 cu.ft. gas is produced from a pound of peat having a calorific value from 130 to 150 B.t.u. per cu.ft. These producers have the great advantage that peat containing as high as 25 per cent or over of moisture can be used. The most economic method of course for using this is for driving gas engines, but engines of large units have not yet proved very satisfactory in this country. In Europe they are operating and have been for a large number of years apparently with a high degree of satisfaction. It therefore appears that for the present it would be most desirable to use this gas under boilers for raising steam.

Ammonium Sulphate Successfully Recovered Abroad

When the peat contains nitrogen, the latter is converted in the producer to ammonia, which can be recovered as ammonium sulphate and prove very profitable. There are several plants in existence in Germany, Italy, Holland and France where the Mond producer, modified by Lihme, is working very successfully. In these producers, gas of about the same quality and quantity as described above is obtained and in addition thereto about 80 per cent of the nitrogen is recovered as ammonium sulphate. These producers are very useful to the peat industry inasmuch as peat containing as high as 42 per cent moisture can be used satisfactorily. In Germany peat containing 50 per cent water and 1.05 per cent nitrogen has been operating for eight years or more delivering a gas of 150 B.t.u. and producing 70 lb. of ammonium sulphate per ton of theoretically dried peat. The nitrogen content of the Italian peat is 2.3 per cent and they recover 215 lb. of ammonium sulphate per ton of theoretically dried peat.

Previous to the war the peat was excavated, dried and conveyed to the producers at a cost of 60c. per ton of peat (theoretically dried). In an ammonia recovery producer the ammonium sulphate obtained will generally cover the total cost of the peat and also the maintenance and operating expense of the gas plant, and even then show a profit. When peat has to be converted into combustible gas it is very easy for a power plant to take this gas and use it for raising steam or generating power by direct explosion in a gas engine. The gases from a peat producer are composed on an average of 20 per cent carbon monoxide, 9 per cent carbon dioxide, 1 per cent ethylene, about 4 to 5 per cent methane and 6 per cent hydrogen; while an average gas from an ammonium recovery producer contains 10 per cent carbon monoxide, 20 per cent carbon dioxide, 20 per cent hydrogen and 5 per cent methane. The building of large gas engine units to use low power gases cannot be an impossibility. Since this has been achieved satisfactorily in Europe, our American power engineers must make up their minds to design an efficient engine of this type, else they will have to be imported from Europe. The power engineer can easily realize from the figures given that we have here an economical and cheap source of power, but it must be realized that economic results cannot be obtained unless large installations are designed and that our capitalists must be willing to break a new path in developing and utilizing a resource so easily obtainable.

Conclusion

There is no difficulty whatsoever in either using a peat for steam raising as a powdered fuel or using a peat in a gas producer. The difficulties, or better the failings, in producing peat as a source of fuel lie in the lack of attention which has been paid to the excavation and drying of the same and the poor engineering ability which has tried to overcome these troubles.

Industrial Laboratories,
New Brunswick, N. J.

Concrete Tanks Used for Water Storage

The test of concrete tanks made of 1:2:4 mixture and used for water storage, undertaken by the Bureau of Standards, Department of Commerce, has been discontinued after 150 days because the day-loss curves have taken the form of a straight line, showing that the daily loss has become constant. It may be of interest to note that these tanks, although showing some actual loss, due to water penetrating the concrete, remained dust dry on the exterior. It would seem from this that although the head of water was 35 ft., the mixture is sufficiently waterproof for this purpose.

Aluminum Rolling-Mill Practice—V Finishing Operations

Production of Thin Sheets to Exact Gage, Hardness and Required Surface Finish Is Described in Detail, Together With the Associated Shearing, Annealing, Inspecting and Shipping Operations*

BY ROBERT J. ANDERSON AND MARSHALL B. ANDERSON

PRIOR to finishing and after the slabbing operation, aluminum slabs are roughed on roughing mills. In general, all sheets which are to finish lighter than 0.080 in. (2 mm.) thick are roughed to within two gage numbers of the finished gage e.g., slabs which are to be rolled into 16-gage sheets are roughed to 14-gage. There are certain exceptions to this rule, and these will be pointed out later.

Ordinarily, sheets which are to finish wider than 48 in. (1.2 m.) and longer than 144 in. (3.7 m.) are rolled singly, while smaller sheets are rolled in pairs. When roughing singly, only one sheet is on the mill, but when rolling in pairs, the roller is passing one sheet through the rolls while the catchers are returning the other sheet over the upper roll. One roller and two catchers can operate a roughing mill, and the production is variable—from 500 to 1,000 lb. per hr. (225 to 450 kg.). The number of passes given, during roughing, and the percentage of reduction depend upon the size and gage of the desired sheets, and to a less extent upon the condition of the mill. Under normal conditions, ten to forty passes are given with three or eight sets of the mill, the variations being due to the gage and the condition of the mill.

After cold roughing, the ends of the rough sheets are sheared so as to prevent undue cracking on finishing; ordinarily, only a small amount of scrap results here, and shearing may be omitted if the ends of the sheets are in good shape. As a matter of fact, it is better to say that sheets to be rolled in pack (20-gage and lighter) are sheared, while those rolled singly (heavier than 20-gage) are not. In general, however, sheets for pack finishing are sheared on both ends and sides, because they are more liable to crack during finishing than the heavier gages.

As has been mentioned above, all sheets, with some exceptions, are roughed to within two gage numbers of the finished gage. In rolling 20-gage (0.81 mm.) sheet, however, the slabs are roughed to within one number of the finished gage, i.e., 19-gage. In roughing, 20-gage is run two in a pack, and the roller will roll one sheet at a time until the sheets are thin enough to run in pack. For 20-gage sheet, the hot-mill slab is cold slabbed to $\frac{1}{8}$ in. (3.2 mm.) and during preliminary roughing the roller will take one sheet and make about six to eight passes with two sets of the rolls. This is repeated for three other sheets, so that the metal is finally run two in a pack and in pairs, i.e., there will be four sheets on the mill. While the roller is passing one pack through the mill, the catchers are passing the other pack back to the roller over the upper roll. As each pack is finished, the metal is stacked on trucks adjacent to the mill by the catcher.

When aluminum is rough-rolled, it is dull gray in color, as no buffs are used on the roughing mill. During roughing, the rolls and the rough sheets are occasionally rubbed over with a swab soaked in kerosene, so as to prevent the metal from sticking to the rolls.

An indicated above, some rough sheets are sheared so as to lessen the liability of further cracking during finishing. All sheets to be run in pack are sheared $\frac{1}{2}$ in. (1.3 cm.) on each side and whatever amount on each end as is necessary to remove the cracked metal at those places. Occasionally, thick sheets run singly crack during the roughing operation; it is then necessary to shear off the cracked metal so as to prevent further cracking. Cracking during rolling may affect the total scrap loss if it becomes excessive.

FINISHING ALUMINUM SHEETS

Cold finishing to gage is performed upon a mill similar in its general features to a roughing mill except that buffs are used on the rolls to keep them polished. Most of the sheet aluminum is sold as planished sheet, i.e., highly polished, and the rolls must be kept bright and free from dust and flakes of aluminum.

Two buffs are used on each mill, one for each roll. Buffs are made by nailing two 1-in. boards together at an angle of 90 degrees; the boards should be 4 to 6 in. wide; the lower board should be as long as the rolls are wide, but the upper board should be sufficiently longer so that it may rest on the roll boxes. The space in the 90 degree angle is filled with waste, and heavy duck is tacked from one board to the other so as to hold the waste in place. Then two pieces of cloth, the length of the boards and 8 to 10 in. wide, are placed together and nailed to one board so that the free end may drag on the roll. The buffs, built up in this way, are secured with bolts and nuts to the roll box so that they rub against the revolving rolls.

A product known as "gray plate" is manufactured on finishing mills with the buffs removed. The surfaces of so-called "finished sheets" are bright and glossy, while those of gray plate are dull and gray. Gray plate is run most often in 14- to 17-gage, and is used considerably for cooking-utensil stock. Gray plate is cheaper to manufacture than finished sheet, for it can be rolled faster. Indeed, manufacture of gray plate may be regarded properly as roughing to finished gage.

In the manufacture of planished sheet aluminum, the finishing operation calls for running down the rough sheets with from twenty-five to forty passes with one set of the rolls, which brings the sheet nearly to gage; the rolls are given such an additional set as will bring

*For parts I, II, III and IV see CHEM. & MET. ENG., March 17, 24, 31 and April 7, 1920, pp. 489, 545, 599 and 647.

the sheet exactly to gage with five or six additional passes. After finishing to gage, the metal will be sent to the squaring shears, where it will be cut square to the required sizes.

Ordinarily, sheets to finish 20-gage and lighter are run in pack, while heavier sheets are run singly. The number of sheets per pack varies with the gage and depends upon whether the ultimate sheet is to be dead soft annealed or hard rolled. If dead soft annealed sheet is being rolled, more sheets can be run in a pack for a given gage than where hard rolled or intermediate sheet is desired. This is so because the soft sheets will be annealed after finishing, and annealing will remove any buckles or waves in the metal. If too many sheets are rolled in pack for a given gage, the ends will curl up, and it is exceedingly difficult to straighten the metal later. As a rule, however, the number of sheets per pack for various gages will be about as shown in Table XIV.*

Light gage sheet must be rolled in pack, because it is otherwise impossible to reduce the metal to gage; this is true for the reason that the rolls are nearly tight from 26-gage (0.4 mm.) up, and to reduce the metal it is necessary to roll several sheets together. Rolling in pack might appear to be a method of speeding up production, but this cannot be regarded as a correct statement for a wide range of gages. Thus, while it is possible to roll more 20-gage sheet in pack than 18-gage singly, it is not possible to roll lighter gages in pack as fast as say 10- or 12-gage.

The figures in Table XIV vary with the condition of the mill, the kind of sheets rolled, and the iron content of the aluminum. As a general procedure, sheets to be rolled in pack are first given a few passes singly (starting with the already roughed sheets); they are then rolled two in a pack, then three, and so on; as the thickness is reduced, the pack is built up. In rolling to gage, whether singly or in pack, the rolls are occasionally swabbed off with kerosene so as to prevent the sheets from sticking. Production is variable, depending upon the gage and size of sheets; figures obtained vary from 100 to 200 lb. per hr., and a yearly average for a plant of capacity 25,000 lb. (11.5 metric tons) per day was 120 lb. (54 kg.) per hr.

Flattening

In order to remove slight buckles and waves in aluminum sheets and make them flat, the sheets are run through a "flatter." Flattening is an effective operation on sheets from 8 to 17 gage (3.26 to 1.15 mm.). Where a perfectly smooth, unmarked surface is called for, flattening should not be attempted, since the flatter rolls may mar the surfaces of the sheets. As a matter of fact, however, sheets should be made on the mills and not on the flatter, and buckled sheets are due to high ridges on the rolls.

Finish Shearing

Commercial aluminum sheets as they appear on the market are finish sheared, squared, and cut to the desired size. The scrap loss arising from shearing may, at times, be considerable, and this is usually the result of mis-shearing and poor finishing practice, although the condition of the metal and the mills, the previous roughing, hot rolling and calculations may all be contributory factors. When sheets are to be cut to a specified size, the usual scrap allowances for shearing on the sides and ends are as given in Table X.†

Shearing, as already pointed out, is a simple mechanical operation, devoid of any features of descriptive interest, but it should be performed by competent shearmen; poor shearing practice invariably leads to high scrap losses and increases production costs. If sheets are sheared too large, they must be re-sheared, and if cut too small they must also be re-sheared to work them into other orders.

Some sheet aluminum goes on the market in the form of circle stock, particularly for the fabrication of aluminum utensils. Much circle stock is made from strip-rolled metal; the strips are sheared into squares; and these are cut into circles on a circle shear allowing ½ in. for scrap, i.e., a side of the square should be 1 in. (2.54 cm.) greater than the diameter of the desired circle. The usual practice in circle shearing is to shear before annealing, since soft metal will bend too readily and get out of shape; further, annealed aluminum will burr badly on shearing. This can be avoided entirely by shearing cold-rolled sheets and strip.

Strip Rolling Aluminum

As previously mentioned, some sheet aluminum is finished to gage on strip mills, so called because narrow slabs or strips are rolled. The product is known as strip metal, coils, etc. It has been said that D and E ingots‡ may be used for strip rolling because the metal is here drawn out rather then spread. High-scrap ingots will result in heavy losses due to cracked sheets in finishing mills, but these ingots work very well in strip mills. Slabs for strip rolling are sheared on both ends and sides, and the slab is reduced to gage with from ten to twenty passes; for example, a ⅜-in. or a ¼-in. slab will be reduced to 14- and 20-gage respectively with about fifteen passes (9.5 or 6.4 mm. is reduced to 1.63 or 0.81 mm.). The first passes should be heavy and the last ones light.

A special lubricating oil is used to lubricate the rolls, but if used in excess as the strip is nearing gage, it does not allow a bright finish on the surfaces of the strips. Hence, on the first two or three heavy passes, it is good practice to use much oil, and as the reductions become lighter as the metal nears gage the excess of oil should be removed. In that way, a bright, glossy appearance will be imparted to the sheets.

There are but two rolling operations in the manufacture of strip metal, viz., hot rolling and strip rolling; no slabbing or roughing is performed. Three men can operate a single unit strip mill, i.e., one roller and two catchers. As a strip becomes elongated by rolling, it becomes increasingly difficult to handle because of its length. Hence, at about 14-gage, the catchers will coil the strip into coil boxes so as to facilitate handling. All strip mills should have a self-coiler as an accessory part; such a coiler will permit a mill to be run with one roller and one catcher. When finished, the strip is cleaned in a strip cleaner and re-coiled.

Strip may go on the market in the form of coils, squares, rectangles, circles, etc. Narrow coils are manufactured by slitting a wide coil into several long pieces on a gang shear, which also rewinds the separate coils so produced. The slab-shear scrap from the strip mill will be greater in quantity than from finishing mills,

*Chem. & Met. Eng., vol. 22, No. 13, March 31, 1920, p. 604.

†Chem. & Met. Eng., vol. 22, No. 13, March 31, 1920, p. 601.

‡Chem. & Met. Eng., vol. 22, No. 12, March 24, 1920, p. 548.

because all slabs for strip metal are sheared on both ends and sides; usually slabs for sheets are sheared only on the ends.

Strip Cleaner

Strip-rolled aluminum is cleaned in a strip cleaner for the purpose of removing lubricating oil. Any oil remaining on the metal will result in a brown or black discoloration on subsequent annealing. A strip cleaner may consist of a cast iron vat supported on four legs; inside dimensions of the vat may be about 4 x 6 ft. (1.2 x 1.6 m.). At one end of this vat, a smaller vat is fastened; this latter is filled sufficiently full with gasoline, and the coil of strip is run through the gasoline. At the other end of the larger vat, a self-coiler is attached. A series of motor-driven rolls for guiding the metal is placed at intervals in the cleaner, and the large vat should be filled with sawdust. To clean a strip, the coil will be placed in the vat of gasoline and one end of the strip will be forced through the rolls, down into the sawdust, and up through a set of revolving brushes to the self coiler.

In some places, soap and water has been used instead of gasoline; a soap which will emulsify the oil on the strip may be effective, but it is the writers' experience that it is far safer to use gasoline for effective cleaning, in spite of the fire hazard. Carbon tetrachloride is a highly effective agent for removing strip-metal oil, but the cost is much higher. Too much emphasis cannot be laid upon proper cleaning of strip coils which are subsequently to be annealed.

Production of Intermediate Sheets

Aluminum sheets, whether finished, gray plate, or strip rolled, may be furnished in various hardnesses; sheets are thus furnished as soft annealed, intermediate, and hard rolled. The hardness is usually measured by the Shore scleroscope, which, while it cannot be entirely accurate for light gages, is sufficiently accurate for all practical purposes. Soft annealed sheets are produced by annealing the products of the finishing and strip mills, while hard-rolled sheets constitute the products of these mills. Intermediate sheet may be in various hardnesses between those of annealed and hard rolled sheet.

In dealing with sheets of intermediate hardness, it is convenient to use a series of symbols for different kinds of sheet. Thus, suppose dead soft annealed sheet is called *XA*0 and hard rolled sheet is called *XAH*; then sheets of intermediate hardness may be called *XA*2, *XA*4, *XA*6 and *XA*8. Provided the previous percentage of reduction is the same for all gages, it is correct to say broadly that the Shore hardness numbers corresponding to these grades in aluminum sheets will be as shown in Table XVI. The methods of manufacturing intermediate sheets are perforce empirical, and a large number of combinations are possible. It is possible to produce intermediate sheets by annealing the partly finished sheet at a gage equal to the finished gage minus the number indicating the intermediate hardness desired. Thus, in making *XA*2 sheets, 18-gage, the partly finished sheet would be annealed at 16-gage, or after roughing. If *XA*6, 18-gage sheet was to be made, the annealing would be done at 12-gage (in the roughing operation); after annealing, the rough sheets would be brought back to the mill, roughed to 16-gage, and then sent to the finishing mill. In the manufacture of *XA*½*H*, or *XA*7, 16-gage, it is necessary to anneal at ⅛ in. in the slab; that is to say, the hot-mill slab is cold slabbed to ⅛ in., and then annealed. The annealed slab is then sent to the roughing mill and roughed to 14-gage, and finally sent to the finishing mill and finished. More simply explained, a broad dictum may be laid down with regard to the annealing for the production of intermediate sheets: Usually such sheets will be annealed *n* gage numbers from the finished gage, where *n* may be 2, 4, 6, 8, etc., in the terminology *XA*2, *XA*4, *XA*6, and so on.

TABLE XVI. SHORE HARDNESS NUMBERS FOR VARIOUS GRADES OF ALUMINUM SHEETS

Grade	Shore H. N.	Grade	Shore H. N.
XA0	4 to 5	XA6	10 to 11
XA2	6 to 7	XA8	12 to 13
XA4	8 to 9	XAH	14 to 15

Annealing Aluminum Sheet

The usual practice employed for annealing cold-rolled sheet aluminum entailed heating the metal for periods of time varying from 18 to 30 hr. at about 370 deg. C. Late reports indicate[9] that at some plants this annealing period has been changed to 2 to 5 hr. at 350 to 500 deg. C. The shorter period is certainly a much more rational procedure, because hard-rolled aluminum may be softened with only short annealing periods at moderate temperatures.

At the present time, aluminum sheet is annealed in gas- or oil-fired furnaces and in electrical furnaces. The car-type electric furnace shown in Fig. 3 has been used for annealing; accurate control of the annealing temperatures is readily possible in this furnace. Annealing furnaces may be built in various sizes according to the desired capacity; for example, a furnace may have inside dimensions of 35 ft. long x 8 ft. wide x 6 ft. high (10.7 x 2.4 x 1.8 m.) The shell of the furnace is built up from ⅜-in. (10-mm.) steel plates, held together with rods and I-beams; adjacent to the steel plates is a layer of common brick, then a layer of kieselguhr, and then a lining of firebrick.

Metal to be annealed is placed upon large iron plates in staggered piles, so as to allow free access of the heat to all parts. The plates with the piles of aluminum are placed by crane upon small cars, and these are pushed into the furnace. It is convenient to have the tracks for the cars extending to about 20 ft. (6 m.) beyond both the front and rear doors of the furnace, so that the cold metal to be annealed may be loaded at one end, and the annealed metal withdrawn from the other end. After the anneal, the aluminum is removed from the furnace and allowed to cool in air.

Some further aspects of the annealing and recrystallization of cold-rolled aluminum sheet have[10] already been dealt with by one of the writers, and these matters will not be further amplified in this place. It will be pointed out again, however, that cold-rolled aluminum sheet after various heavy reductions may be softened to 4 to 5 Shore hardness by relatively short annealing periods at moderate temperatures. For an-

nealing slabs and large sheets, a car-type furnace appears to be entirely satisfactory. For annealing utensil stock, a continuous furnace will doubtless prove more advantageous.

Inspection of Aluminum Sheet

After aluminum sheets have been rolled to gage, sheared to size, and annealed if necessary, they are sent to an inspection room to avoid much trucking of the metal back and forth. Sheet aluminum may be inspected conveniently on benches about waist high. Two men should be able to handle the inspection for a mill rolling 25,000 lb. (11,350 kg.) of sheet per day. Two men are needed for inspecting, because it will be difficult for one man to turn over the larger sheets for inspection on both sides.

In mill practice, carbon copies of the orders or lot numbers should be furnished to the inspector. When a lot of metal is ready the inspector will indicate the total number of pounds accepted and rejected on his carbon copy and return this to the office. The inspector will also keep a detailed account in a book provided for that purpose of the number of pounds of sheet inspected daily, the amount passed, and the amount rejected, and make notations as to the reasons for rejection. The inspector should also collect data daily from the hot mill records with regard to the total weight of ingots rolled, and from the slab-shear reports as to the weight of slabs sheared and the scrap.

With this information, the office should render a monthly report to the superintendent showing the vital figures which affect the operation of the mill. Over a period of a year, such a report will appear as in Table XVII, giving detailed figures for defective sheets and the reasons for the defects.

A detailed explanation of the table may be advisable. Ingot weight refers to the total amount of ingots broken down in the hot mill to slabs during the periods indicated. Slab weight is the total weight of slabs after shearing; the scrap loss due to shearing averages about 10 to 12 per cent for reasons already explained. Where the scrap loss due to slab shearing is less than 10 per cent, this may be due to the fact that the hot roller broke down more ingots than a certain order called for, say eleven ingots instead of ten; the resultant slab weight would be greater than the apparent amount of metal rolled (as shown by the hot-mill lot requisitions). This happens quite often because of carelessness at the hot mill. Figures for total weight of finished sheets rolled are obtained by weighing the lots as they are delivered to the inspection department; weights for accepted and rejected sheets are taken during inspection. The sum of the weights of the finished sheets rejected because of various defects should equal the total weight of rejected sheets shown in column 5 in the table, but usually these weights do not check. The discrepancies result from errors in weighing, and neglecting to weigh part of the rejected material, as well as from mixing accepted and rejected metal. This is due, of course, to carelessness. Scrap losses resulting in rolling aluminum to finished sheets usually average about 35 to 40 per cent, as shown in column 7; this scrap figure is obtained from the formula

$$100 \quad \frac{\textit{Weight finished sheet rolled}}{\textit{Weight ingots rolled}} \times 100$$

In the same way, the total amount of scrap, including sheets rejected by the inspector, is obtained from the formula

$$100 \quad \frac{\textit{Weight finished sheets accepted}}{\textit{Weight ingots rolled}} \times 100$$

Defects in Finished Sheets

Usually, all sheets are carefully examined for surface defects, cracks, stains, buckles, scratches, etc. Whether any sheet is rejected or not will depend upon the specifications, if any, and the seriousness of the defect.

Blisters are usually sufficient cause for rejection, and this defect is one of the most serious with which the aluminum-rolling mill is concerned. Blisters are thought to result from annealing at too high temperatures; there is little doubt that high annealing temperatures *per se* are sufficient to cause blistering, but whether this

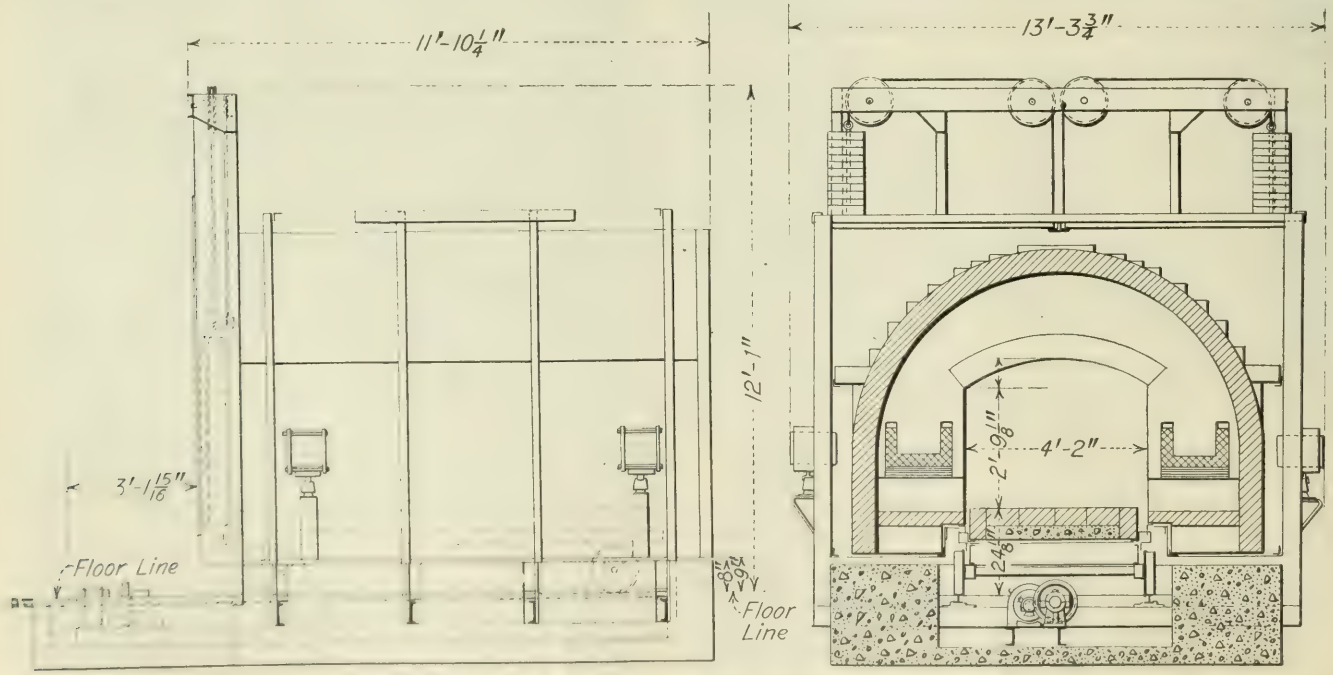

FIG. 5. CAR-TYPE ELECTRIC FURNACE (ELECTRIC FURNACE CO.)

trouble is also intimately associated with gas absorption on melting for casting into ingots is not clear. The facts are that accurate information with regard to this matter is lacking, but corrective measures to reduce the scrap losses from blistering are urgently needed.

In aluminum-rolling parlance, "slivers" are understood to describe the flaking of the metal in long splinters; this occurs on rolling, and entrained dross will usually be found associated with slivers. The explanation offered for this defect is that, during rolling, some of the mechanically entangled dross is forced near the surface of the sheet until this dross is held under a very thin film of metal. The dross is elongated in the direction of rolling, and when finally the film becomes extremely thin, the metal covering the dross flakes off in long splinters—called slivers. This is distinctly a surface defect and ruins the sheets for most purposes.

Roll marks are the buckles or waves in sheets resulting from a high ridge on the finishing rolls; where the sheets must be perfectly free from scratches, the flatter cannot be used for the purpose of ironing out the buckles, and therefore rejections follow.

Scratches result largely from handling. Pulling one sheet over another, so that the slight burr on the edge of the one sheet scrapes across the face of the other is a prolific cause of scratches. Scratches also are the result of handling on shearing, of flattening, and piling and stacking.

Cracks and splits are due to rolling, and often they can be avoided only with much difficulty. Cracks are more numerous in rolling the light alloys than aluminum itself because of their greater hardness. Sheets rolled from ingots made from high scrap heats are also fairly prone to crack on rolling.

"Dirt" means simply the entrained dross which is forced to the surface on rolling; it is sufficient cause for rejection.

Regarding stains, it is advisable to distinguish between oil stains and water stains. Oil stains are usually found on strip rolled metal, and result from the burning of residual oil during annealing. They can be largely eliminated by observing the proper amount of care in cleaning. Oil stains are various shades of brown to black color, and can be readily distinguished from water stains. Aluminum, like copper, may absorb considerable amounts of moisture even on exposure to atmospheres of high humidity; on annealing, this absorbed water is driven to the surface and may cause a whitish stain of a powdery character. This powdery product appears to be oxide of aluminum, although precise information as to its chemical composition is not available. If aluminum sheet, prior to annealing, becomes wetted with water by rain coming in through windows or skylights, it will usually have this white stain after annealing. The stain is objectionable and results in rejection of the sheets.

In column 17 wrong shearing refers to mis-shearing at the finishing shears, and usually sheets sheared wrong are sheared too narrow or too short. "Short" means the fairly large pieces which are found to be too small to shear to the required size; short sheets are the result of miscalculations, rolling the wrong size ingot, cracking on rolling, and shearing to stop further cracking. Short sheets are not necessarily a total loss, although they may not be applicable to the lot in which they were rolled; they are usually worked into other lots by re-shearing to a smaller size, or cut up into squares for circle shearing. Also, short material may

1 lb. = 0.454 kg. (a) This figure includes shearings, buckled and twisted slabs, etc. (b) Finished scrap in process refers to the scrap resulting in the manufacture of finished sheets, exclusive of inspector's rejections, and includes sheet strips, buckled sheets, etc. (c) This figure embraces all the scrap and includes the finished scrap in process, plus the inspector's rejections

be put in stock and allowed to accumulate for a given period of time.

Inspection Record

If properly interpreted, inspection records are very valuable for the purpose of deciding what preventive measures must be taken to reduce scrap losses. In fact, if scrap figures are plotted weekly in the form of graphs, the interpretation may be readily had at a glance. It is not possible, in the present article, to deal with this subject in exhaustive detail, and it is the writers' object now merely to afford an insight into how inspection records may be gathered and their data interpreted. Both blisters and slivers are difficult to eliminate if high scrap ingots are rolled, but measures for preventing scratches are more obviously and easily applied. After all, the predominating factor which determines the scrap losses in aluminum rolling-mill practice, as in any other industry, is the quality of the supervision.

Shipment of Aluminum Sheets

For shipment, aluminum sheets are packed in paper and boxed or crated. Because of the relatively high value of the metal in sheet form, the packing and shipping should be carefully done. If sheets are loosely packed, so that they slide on one another in transit, there is danger of scratching even though the sheets left the mill in perfect condition.

Commercial Pottery of Japan

IT IS characteristic of Japanese ceramics that the numerous varieties have always been distinguished from one another geographically rather than technically. Thus Satsura ware, Imari ware, Awata ware, etc., names well known to foreign connoisseurs, refer to the districts in which the pottery is made. Japanese wares may be classed roughly in three groups:

1. Stoneware, including tiles and various utility objects, usually glazed and ornamented only by stamping or scoring, made in many parts of Japan and chiefly consumed locally.

2. Faience, most often with a crackle glaze, and highly decorated. It is not fired at so high a temperature as porcelain and is consequently softer and more fragile; but, for the same reason, more delicate colors may be used in decoration. Much of this sort of ware has found its way abroad under the designation of "curios."

3. Hard porcelain and semi-porcelain.

The porcelain of Japan is made in a different way from that of China. Having been fashioned, it is baked in a biscuit state, then painted with such colors as require a great heat and the glaze applied, then burned again at a much higher temperature; any further decoration in enamel colors or gilding is subsequently fired in a muffle kiln. These numerous firings are less tenacious than those used in China, hence Japanese specimens are frequently slightly out of shape.

Production and Export

The value of the earthenware and porcelain produced in all Japan for the year 1918 was 44,214,084 yen (approximately $22,107,000). The relative production of different classes of potteries for 1917 was as follows: Ornaments and art objects, 18 per cent; dishes, 56 per cent; industrial goods, 10 per cent; toys, 5 per cent; miscellaneous, 11 per cent. Table I shows the production of pottery in Japan for the years 1909 to 1918, inclusive, yen having been converted to dollars at the rate of $0.50 to 1 yen.

A glance at the export statistics will show that whereas in the first half of the decade from 1909 to 1918 the export of pottery from Japan kept about the same figure, yet from the beginning of the war the annual export steadily increased until the amount for 1918 had grown to four times the figure for 1914. Before the war the United States took nearly half of Japan's production, but in 1918 this proportion had shrunk to less than one-fourth.

TABLE I. VALUE OF THE POTTERY INDUSTRY IN JAPAN FOR THE YEARS 1909 TO 1918

Year:	Value	Year:	Value
1909	$6,178,838	1914	$7,828,428
1910	6,634,997	1915	8,766,124
1911	7,447,801	1916	12,610,174
1912	8,272,772	1917	14,669,216
1913	8,838,417	1918	22,107,042

In Table II are given the total values of exports of pottery from Japan for the years 1909 to 1918, inclusive, together with the values of such goods destined to the United States.

TABLE II. VALUE OF THE POTTERY EXPORTS FROM JAPAN FOR THE YEARS 1909-1918

Year	Total Export	Export to United States	Year	Total Export	Export to United States
1909	$2,628,416	$1,448,636	1914	$2,955,884	$1,572,374
1910	2,756,961	1,391,036	1915	3,476,476	1,455,072
1911	2,732,799	1,368,383	1916	6,051,996	1,095,694
1912	2,725,799	1,293,170	1917	7,238,967	2,470,395
1913	3,348,668	1,564,350	1918	9,976,896	2,229,467

The classes of porcelain and semi-porcelain products which enter largely into the export trade are: Tableware, including all the pieces comprised in ordinary dinner sets; sanitary ware, such as washbowls and other bathroom fixtures; electrical porcelain, such as insulators, sockets, etc.; and toys and novelties.

Tables III and IV give the analyses of a few typical Japanese kaolins, clays and porcelain stones.

TABLE III. ANALYSES OF JAPANESE KAOLINS AND CLAYS

Variety	Percentage of SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	K_2O	Na_2O	H_2O
Shiga-raki (Kipto)	56 87	28 56	0 98	0 69	0 47	2 08	0 06	10 16
Owary (Seto)	54 65	32 35	....	0 90	0 37	3 27	2 22	6 30
Hizen (Arita)	49 25	38 89	1 14	0 15	0 36	2 01	0 39	5 90

TABLE IV. ANALYSES OF JAPANESE PORCELAIN STONE

Kind of Stone	Percentage of SiO_2	Al_2O_3	Fe_2O_3	CaO	K_2O	Na_2O	H_2O
Arita stone I	78 70	14 27	1 16	0 45	2 24		3 29
Arita stone II	83 00	11 60	0 70	0 18	1 90	0 29	2 49
Amakusa stone	73 87	15 25	0 73	0 43	5 46	1 07	2 23
Kutani stone	76 60	14 75	0 86	0 29	3 91	0 65	2 68

The wages in the Japanese pottery industry are exceedingly low when compared to those received for similar work in the United States. Thus the average daily wages received by the workers during 1917 and 1918 were: Girls under seventeen, 0.60 to 1.20 yen; girls over seventeen, 0.90 to 1.30 yen; men under seventeen, 0.60 to 1.25 yen; and men over seventeen, 1.20 to 2 yen. (1 yen = about 50c.) To these figures must be added a rice stipend granted to equalize the present high cost of living.

Legal Notes

By Wellington Gustin

Governmental Power Over Manufacturers

The manufacturer and others engaged in large business enterprises have felt very keenly within the last few years the encroachment of governmental power and authority.

Just what are the limits of authority of governmental officials is hard to determine. The officials naturally appropriate all possible, feeling that the parties affected will assert their own rights and thus arrive at the proper limitation or line of authority between them. The power and authority of the Federal Government is limited to subject matters granted to it by the states, but just where this line lies is left to a determination by the courts. The power to control and regulate commerce between the states was given to the Federal Government. But what is commerce? Are you engaged in commerce which comes under Federal regulation? Are you simply a manufacturer, and as such, not amenable to certain acts of Congress?

Demand of the Federal Trade Commission

In a recent decision the United States District Court sustained the contention of the Basic Products Co. against the Federal Trade Commission, which body, pursuant to a resolution passed by it, had demanded an opportunity to examine any documentary evidence which related to the organization, business, conduct, practice and management of the corporation and its relation to other corporations, and to individuals, associations and partnerships, in order that copies may be made of any portions of said documentary evidence as appears to be relevant to the subject matter of its "investigation." Among more general demands there was the following: "In particular, the Federal Trade Commission demands that it be permitted to examine and take copies, if deemed advisable, of all documentary evidence which relates to the production costs, annual production, and capital investment in the manufacturing of a commodity known as 'Syndolag.'" After service of this demand certain examiners for the Commission presented themselves at the office of the Basic Products Co. at Pittsburgh to secure the desired information, which was refused. The Attorney General, in the commission's behalf, then asked for a writ of mandamus to compel the Basic Products Co. to allow the investigation of its records as desired. (260 Fed. Rep., 472.)

Secrets Refused by Company

The company answered the petition for the writ, saying it had developed "Syndolag," a patented article, after a great expenditure of time and money, and which, besides its other uses, is widely sold by it for repairing the bottoms of open-hearth steel furnaces, a purpose for which heretofore only imported Austrian magnesite could be used. It further averred that in the production of the article it has developed certain refinements of method which are and have been kept secret by the company and which constitute trade secrets of great value, as are also the cost accounts relating to the production of such article.

For further answer the company averred that the Navy Department ordered 250 tons of Syndolag, quoted by the company at $35 per ton, but the Department required the billing at $30 per ton; that under the order 64.9 tons were delivered, the contract being cancelled due to the signing of the armistice; that thereafter repeated demands were made by the Navy Department for affidavits showing cost of production of said article for the pretended reason of enabling the Navy to decide upon a price it would be willing to pay the company for the product; that it then offered, and still offers to accept any price for the material which the Navy may see fit to pay; that while the Navy's demands were being made it nevertheless paid for all the Syndolag delivered at the rate of $30 per ton; that it offers to return any part of such price or the whole thereof should the Navy be unwilling to fix such price; that regardless the Navy has made the demands without reason or just cause; that when the company refused finally to furnish such affidavits the Navy's demands were taken up with the Federal Trade Commission to obtain such through an assertion of its powers.

In view of these things Judge Orr, who tried the case, says it plainly appears that the Commission has undertaken to ascertain the cost of producing a product which is the subject of a patent, and to ascertain also the annual production thereof and the capital invested in its manufacture and the reasons therefor, as given in the company's answer, must be taken as true.

U. S. Has No Reserved Rights in a Patent

Then the court said that there was no reservation of right in the United States as against the inventor. The United States cannot appropriate or use the invention without just compensation in any different way than it can appropriate or use any other article owned by a private citizen.

Again it said the act of Congress under which the Commission proposed to investigate the cost of producing a patented product, in order that the Navy might acquire the same, does not in terms justify such proceeding. Instead, it said the act was aimed at unfair methods of competition in commerce, such commerce being confined to interstate and foreign commerce. The Commission more particularly relied upon section 6 of the act, in the present case, which appears to authorize proceedings without complaints being required to be served. The opening of that section is as follows:

Powers of the Commission

"That the Commission shall also have the power—

"(*a*) To gather and compile information concerning, and to investigate from time to time the organization, business, conduct, practices, and management of any corporation engaged in commerce, excepting banks and common carriers subject to the act to regulate commerce, and its relation to other corporations and to individuals, associations and partnerships."

Other subdivisions of section 6 are here given in substance:

"(*b*) The Commission may require detailed reports from such corporations under oath.

"(*c*) May investigate whether a final decree, intended to restrain any violation of the anti-trust acts, is being carried out, and upon application of the Attorney General are required to do so.

"(*d*) Upon direction of the President, or either house

of Congress, the Commission shall investigate alleged violation of the anti-trust acts by any corporation.

"(*e*) Upon the application of the Attorney General the Commission shall investigate and make recommendations for the readjustment of the business of any corporation alleged to be violating the anti-trust acts.

"(*f*) The Commission may make public information obtained, 'except trade secrets and names of customers,' and may submit recommendations to Congress for additional legislation.

"(*g*) May from time to time classify corporations and make rules and regulations for the purpose of carrying out the provisions of the act.

"(*h*) The Commission may investigate trade conditions in and with foreign countries."

Powers Claimed by Commission's Counsel

The court said it was plain that Congress intended to give the Commission a power unprecedented in its scope. The counsel contended that under the act the Commission was given the right to investigate any question having to do with any business of any corporation, except banks and common carriers subject to the control of the Interstate Commerce Commission, to conduct a hearing at any point in the United States, and compel there the attendance of any witnesses and the production of any records from any point in the United States.

But this argument, said the court, probably assumed that every corporation, with respect to which the Commission intended to conduct an investigation, was engaged in interstate commerce within the meaning of the act. And nowhere was it made to appear that the Basic Products Co. was engaged in interstate commerce in any other way than any other corporation or any citizen may be so engaged, by making one or more shipments of manufactured goods from one state to another.

Earlier Decisions Regarding Limitations of Power of Congress

Touching upon the limitations upon the power of Congress, and likewise upon the Commission in dealing with the activities of corporations or persons, an earlier decision was cited, wherein the court said:

"That neither the production or manufacture of articles or commodities which constitute subjects of commerce, and which are intended for trade and traffic with citizens of other states, nor the preparation for their transportation from the state where produced or manufactured, prior to the commencement of the actual transfer, or transmission thereof to another state, constitutes that interstate commerce which comes within the regulating power of Congress, and further, that after the termination of the transportation of commodities or articles of traffic from one state to another, and the mingling or merging thereof in the general mass of property in the state of destination, the sale, distribution, and consumption thereof in the latter state forms no part of interstate commerce."

The court then cited an opinion of the Supreme Court of the United States, discussing the lack of constitutional authority over industry (9 Sup. Ct., 101). Justice Lamar said in that case:

"Manufacture is transformation—the fashioning of raw materials into a change of form for use. The functions of commerce are different. The buying and selling and the transportation incidental thereto constitute commerce; and the regulation of commerce in the constitutional sense embraces the regulation at least of such transportation. . . . If it be held that the term includes the regulation of all such manufactures as are intended to be the subject of commercial transactions in the future, it is impossible to deny that it would also include all productive industries that contemplate the same thing. The result would be that Congress would be invested, to the exclusion of the states, with the power to regulate, not only manufactures, but also agriculture, horticulture, stock raising, domestic fisheries, mining—in short, every branch of human industry. For is there one of them that does not contemplate, more or less clearly, an interstate or foreign market? Does not the wheat grower of the Northwest, and the cotton planter of the South, plan, cultivate and harvest his crop with an eye on the prices of Liverpool, New York and Chicago? The power being vested in Congress and denied to the states, it would follow as an inevitable result that the duty would devolve on Congress to regulate all of these delicate, multiform, and vital interests—interests which in their nature are and must be local in all the details of their successful management. It is not necessary to enlarge on, but only to suggest, the impracticability of such a scheme, when we regard the multitudinous affairs involved, and the almost infinite variety of their minute details."

In the case against the Basic Products Co. its counsel contended that section 6 of the Trade Commission act was unconstitutional "in so far as it authorizes investigations and compulsory disclosures of matters which are beyond the commerce power of Congress," and also, "in so far as it attempts to authorize a search or seizure by an administrative agency of the Government without charge or suspicion of wrong doing," and urged upon the court the necessity of so declaring it. However, the court said that while this contention was probably sound, it was not necessary so to do in holding the Commission was without the power to carry on the investigation which it had assumed in the instant case.

Ruling of the Court

Says Judge Orr: "An incident of such investigation is the ascertainment of trade secrets. It is plain that the cost of manufacturing a patented product to which the manufacturer has the exclusive right may be a trade secret, a species of property of great value. This is also true of refinements of method in producing the same. The act prohibits the disclosure of trade secrets. The assumption that no such disclosure will be made disappears before the expressed intention to give the information to the Navy Department. We have then, a contemplated search and seizure, and a contemplated taking of private property for public use, without due process of law, which are violative of the Fourth and Fifth Amendments of the Constitution."

And on another point the court remarked: "It never was intended that the extent of a free man's duty to perform should be determined by those who demand performance."

Exports of Cement From United States

According to data compiled by the statistical division of the United States Bureau of Foreign and Domestic Commerce, the exports of domestic cement during the calendar year 1919 were 2,463,573 bbl., valued at $7,513,389.

Improved Apparatus for Determining Light Oil in Gas

By E. H. Bird

FOR some time the common method for the determination of light oil in coke-oven and illuminating gas has made use of a simple train of absorbing bottles. The method originally adopted by the Koppers Co.[1] specified a train of ten bottles. This has proved to be an efficient procedure and probably will always find use on account of the simplicity of the apparatus required. In a series of tests on this apparatus, when operated according to specifications, it was found to have an efficiency of 99 per cent.

For plant control tests, however, any such bottle train is objectionable on account of the excessive time and attention required to keep it in good order and to empty and refill it for each test. The oil-soaked stoppers easily slip out, the glass connections and bottles are easily broken and the rubber connections quickly wear out. For plant laboratories having regular light oil determinations to make, these are obvious disadvantages and there is too much opportunity for erroneous results due to some little carelessness in keeping the rubber parts renewed and in making the connections tight.

Double Coil Scrubber

The Koppers Co. laboratories undertook the problem of developing a more compact apparatus of adequate absorbing capacity. The work resulted in the invention of the "double coil scrubber,"[2] which has been in use in a number of laboratories for about two years. This apparatus is compact and substantial, having no glass parts, and is, at the same time, easily portable.[3] It provides for intimate contact between oil and gas, and may be emptied by turning a single valve, and refilled through a single opening.

Though designed for the absorption of light oil from coke-oven and illuminating gases, the apparatus may be used for the absorption of any constituent of a gas soluble in a liquid-absorbing medium, provided the absorbent will not attack the metal from which the apparatus is made. For instance, it is well adapted to the absorption of gasoline from natural or casinghead gas. A detachable cooling jacket provides for absorptions at temperatures other than atmospheric.

Design of Scrubber

The apparatus, as shown in Fig. 1, consists of two concentric vessels 13 and 14, made of sheet copper, each of which contains an absorbing coil shown at 4 and 8 respectively. The inner vessel 13 has an outlet pipe 10 at its lower end which is controlled by the valve 9 with handle 20. The outer vessel 14 has an outlet at the valve 12. The gas inlet pipe 1 leads downward into the inner vessel 13 and terminates in a jet 2, through which the gas passes into the coil 4. This jet is provided with an aspirator pipe 3, which forms the oil inlet of the coil. The inner chamber has a gas outlet which connects by a pipe 5 with a second jet 6, which connects with coil 8 and has aspirator pipe 7. The apparatus is filled with absorbing oil through the connection 16. The outlet gas connection from the apparatus is shown at 15. When it is desired to maintain the absorbing oil at other than atmospheric temperature, the apparatus can be jacketed. Fig. 2 shows the apparatus provided with a galvanized iron jacket and connected with a gas meter.

Operation of Apparatus

The valve handle 20 and the filling pipe 16 are opened and the valve 12 closed. About 3,000 c.c. of absorbing oil is poured into the chambers. This brings the oil level just below the outlets of each coil. The filling connection and the valve handle 20 are then closed, the inlet pipe 1 connected to the gas-sampling line and the outlet to a suitable gas meter. The gas is passed through the absorber at a definite rate, 2 cu.ft. per hr. being suitable for benzolized gas and 4 cu.ft. per hr. for debenzolized gas. The gas first passes through the inlet pipe 1 into the jet 2, from which it bubbles through the coil. In passing through this coil it is held in intimate and prolonged contact with the oil in the coil. The aspirator action of the jet is such as continually to draw fresh oil in through the aspirator pipe 3. The oil with which the gas comes in contact is expelled at the upper end of the coil. The gas then passes through the coil in the outer chamber in a similar manner and passes out to the meter. After the expiration of the absorption period the valve 9 is opened and the contents of both vessels drained from valve 12. The vessels will drain in a short time, but it is best to rinse out the apparatus by pouring in a little fresh oil in the opening 16 and shaking. The oil is then subjected to

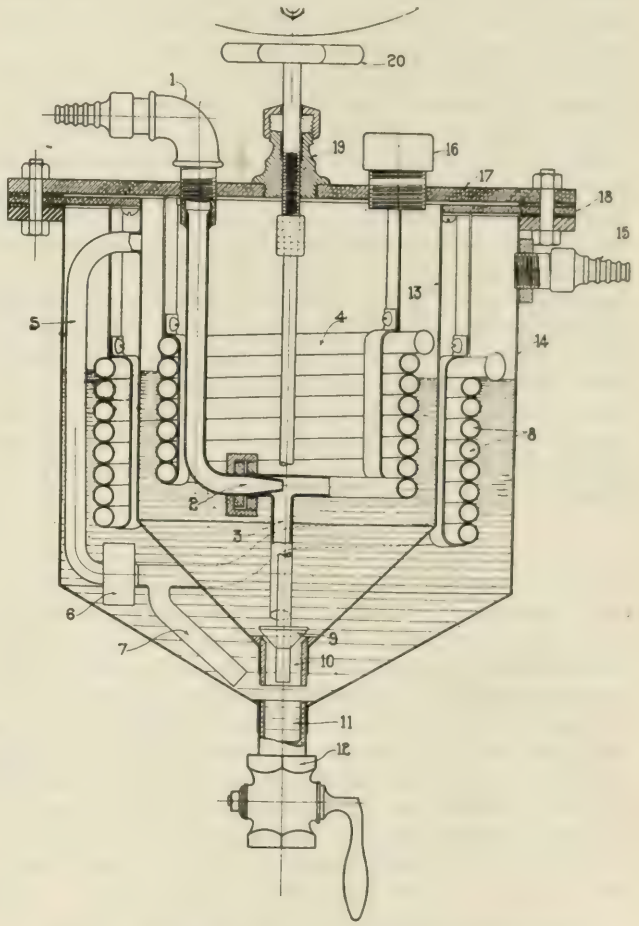

FIG. 1. SECTION OF DOUBLE COIL SCRUBBER

[1] F. W. Sperr, Jr., Met. & Chem. Eng., vol. 17, 1917, p. 550, of article entitled, "Laboratory Methods for Benzol Recovery," pp. 548-555; 586-588; 642-647.

[2] Patented by F. W. Sperr, Jr., and A. A. Kohr, U. S. No. 1,316,602.

[3] Weight of the apparatus without cooling jacket is 23 lb.

the standard steam distillation for the determination of the light oil.

The gas comes in good contact with the oil during the total length of the two coils, which is 20 ft. When the chambers are filled with the proper amounts of oil, about 70 per cent of it is contained in the outer vessel. As this is the last oil to wash the gas, the per cent enrichment does not rise so high as to cause inefficient absorption unless too large quantities of gas are scrubbed. The second chamber, in which the oil is kept separate from the first, is a necessary part of the apparatus, since no matter how thorough is the contact of oil and gas in the first chamber some light oil is lost. This loss is practically nothing at the start of the test, but increases with the enrichment of the oil. The much larger volume of oil in the outer chamber and the previous treatment in the inner chamber allow sufficient gas to be passed before appreciable losses begin to occur.

When the gas is passed through the absorber at a rate exceeding 6.5 cu.ft. per hr., a portion of the gas bubbles out of the aspirator pipes and therefore does not get as thorough contact with the gas as it should. A rate of 4 cu.ft. per hr. is recommended for testing debenzolized gas and 1 to 2 cu.ft. per hr. for benzolized gas. Five in. (water) of pressure is required to operate the apparatus unless suction is used.

This apparatus has been tested in the laboratory as follows: A measured amount of coke-oven light oil, all of which distilled under 200 deg. C., was vaporized uniformly into a current of air and passed through the absorber at a constant rate. A bottle train absorber was attached after the coil scrubber, and the light oil absorbed in this determined by the standard methods and the percentage not absorbed by the coil scrubber calculated. The whole apparatus was operated under suction in order that there should be no back pressure on the coil scrubber. The air was passed through a meter merely to keep the rate constant and to aid in vaporizing the light oil uniformly. One cu.ft. of air carried 1.5 c.c. of light oil (0.396 gal. per 1,000, imitating a coal gas rich in light oil). Three liters of absorbing oil were used in each test.

Efficiency

The efficiency of the apparatus was found to vary with the amount of light oil passed into it and with the rate of gas flow. In some cases, in order to get a measurable amount of light oil in the bottle train, fresh oil was put in the coil scrubber for two or three successive tests, the light oil in the bottle train only being determined after the last test of the series. The per cent enrichment of the oil in the two chambers of the absorber was also determined. On account of the much larger quantity of the oil in the outer chamber, the per cent enrichment is quite low until the oil in the first chamber is nearly saturated.

TESTS AT 2 CU.FT. PER HR.

Test Nos.	C.c. Light Oil Vaporized in Each Test	Per Cent Saturation Inner Chamber	Per Cent Saturation Outer Chamber	C.c. Light Oil in Bottle Train	Per Cent Efficiency of Coil Scrubber
1, 2 and 3	30	2 42	0 22	0.0	100.0
4 and 5	45	2 70	0 706	2.6	97.1
6 and 7	60	2 93	1 12	7.6	93.7

Obviously, the efficiency might also be determined by ascertaining the percentage of light oil absorbed. By such a method, however, the effects of distillation losses are undoubtedly exaggerated. For instance, a distillation loss of 3 per cent of the light oil absorbed in the scrubber would have a much greater effect on the efficiency figure than a distillation loss of 10 per cent of the light oil in the bottle train. Figures obtained for the efficiency of the apparatus by this second method will be given here for what they are worth. By means of blank tests, factors for distillation

FIG. 2. DOUBLE COIL SCRUBBER WITH COOLING JACKET AND CONNECTED WITH GAS METER

loss with different quantities of light oil were determined and applied in the use of this method. Even these corrections are somewhat uncertain on account of the exaggerated effect of small losses. After the application of these factors, the efficiency of the apparatus was found to be the following:

	Per Cent
Tests 1 to 3	98.2
Tests 4 and 5	96.0
Tests 6 and 7	90.0

Tests made at 4 cu.ft. per hr. showed the absorption to be less complete at that rate. When 45 c.c. of light oil was vaporized at that rate, an efficiency of 92.5 per cent was indicated.

It will be seen from the foregoing tests that in testing unscrubbed coal gas an absorption efficiency of practically 100 per cent should be obtained if an amount of gas is used containing about 30 c.c. of light oil. The efficiency with the gas volume containing 45 c.c. of light oil is 97 per cent, which is satisfactory for all plant control processes, and it is recommended that in testing unscrubbed gas the amount of light oil absorbed should not exceed 45 c.c. Tests on unscrubbed gas can be made at a rate of 2 cu.ft. per hr. Debenzolized gas can safely be run at 4 cu.ft. per hr.

The Koppers Co. Laboratories,
Mellon Institute, Pittsburgh, Pa.

Revival of Salt Industry at Inagua, Bahama Islands

American capital operating under the name of the Inagua Salt Co., Ltd., will be responsible for a revival of the salt industry of Inagua, Bahamas. The work is already under way and it is estimated that Inagua will soon be exporting 3,500,000 bushels of salt a year to the United States. The company proposes using several light-draught, three-masted auxiliary schooners for handling this export. Motor trucks and railway trucks will be employed for taking salt to shipping points.

Synopsis of Recent Chemical & Metallurgical Literature

Corrosion of Condenser Tubes.—The fifth report of the Corrosion Committee, presented by GUY D. BENGOUGH, R. M. JONES and RUTH PIRRET at the spring meeting of the Institute of Metals, is confined to the corrosion of condenser tubes (mainly 70:30 brass), and is a study of the practical problems of corrosion in condensers under service conditions, employing either sea water or fresh water. It is divided into four sections.

The first section deals with what has been called the diagnosis of condenser tube corrosion. The procedure to be followed in withdrawing and preparing a tube for examination is described, also the symptoms or appearances within the tube which correspond to each of the five main types into which the practical problems of corrosion under fresh-water or sea-water conditions have been classified. The importance of additional information concerning (*a*) the water supply and (*b*) the corroded tubes toward elucidating the cause of corrosion is shown and emphasized. This information, which is specified, has rarely been obtainable in the past, particularly as regards the water supply, and this may partly account for the lack of appreciation of the importance in corrosion troubles of the conditions existing within the plant. These conditions frequently vary very much from time to time, and it is shown that although the conditions which favor accelerated corrosion may be present for but short periods at irregular intervals, and consequently may not be easily detected, the effect on the tubes may still be very serious. Also in certain cases it is shown that accelerated, localized corrosion may persist after the initiating conditions have disappeared.

The second section is devoted to a consideration of certain features in the structure of condenser tubes, since an appreciation of these is of great value in following the mechanism of the types of corrosion studied later. Attention is principally directed to the presence on the tubes of a surface layer consisting of structureless and highly distorted metal. This layer has undoubtedly a greater resistance to corrosion by saline and fresh waters than the underlying crystalline metal, so that whenever this layer is penetrated corrosion will proceed at an increased rate. The layer has been stripped from a number of tubes of different composition. Its thickness is usually of the order of 0.01 mm., and indications have been obtained that its composition may be somewhat different from that of the underlying metal.

In the third section the five main types of brass condenser tube corrosion are considered separately in detail.

Type I. General Thinning.—This type may be considered as an accelerated form of the complete corrosion which normally occurs in saline solutions, in so far as the tube is gradually and uniformly reduced in thickness. The rate of ordinary complete corrosion is too slow to be of any serious consequence in practice; laboratory experiments with running sea-water have shown that a period of fifteen to twenty years may elapse (even presuming that the rate of corrosion is uniform and does not decrease with time) before a tube is reduced 50 per cent in thickness from this cause. Tubes almost always fail in practice by local action of some kind long before ordinary complete corrosion has seriously reduced the thickness of the tube. Rapid general thinning, however, is essentially a fresh-water phenomenon and is usually associated with the presence of free acid in the water supply. The results of tests on ten samples of tube of widely different composition in hydrochloric acid of concentration 3 parts in 100,000 at ordinary temperature show that in six weeks all tubes had lost from 2 to 4 per cent in thickness. That such a very dilute acid should reduce the thickness of a tube so much in such a short time at ordinary temperature is ample evidence of the serious effect of acid in the water supply upon the life of condenser tubes. Proper neutralization, preferably at the source of contamination, is an effective remedy for this trouble, but considerable difficulty may be experienced in detecting the acid, especially if, as is generally the case, it enters the water supply only intermittently. Regular and frequent tests of the water must be made when this type of trouble occurs.

Type II. Deposit Attack.—The principal cause of pitting which is the most frequent source of trouble in condensers is ascribed to what is termed "deposit attack." In the presence of sodium chloride solutions the cuprous oxide formed on a brass surface gradually changes to cuprous chloride. The latter is usually swept out of a condenser tube by the circulating water, but under various conditions may adhere at different parts of the tube surface. When such adherence has occurred, conditions now allow of the further gradual change of the insoluble cuprous chloride under the influence of oxygen to soluble cupric chloride and cuprous oxide. The action of cupric chloride solution on brass is very rapid, as may be gathered from the fact that a piece of brass tube 2 in. long, placed in a strong cupric chloride solution at ordinary temperature, was completely disintegrated and partially replaced by a pseudomorph in copper in two days. The action involves the oxidation of the copper and reduction of cupric chloride to cuprous chloride; redeposition of copper from solution by the zinc also occurs. In the presence of air cuprous chloride will again be converted to cupric chloride and the attack on the brass continued. Thus the action is both recurrent and local. Foreign bodies, and particularly colloidal bodies, lying in the tube have an injurious effect by serving as loci for the adhesion of cuprous chloride and by preventing the diffusion of cupric chloride. Observations on the incidence and distribution of pits in condenser tubes are shown to agree with the results which would be expected to follow from the above explanation of the mechanism of pitting. Attention is drawn to the importance of keeping tubes clean and as free as possible from foreign bodies as a means of preventing deposit attack.

Type III. Layer Dezincification.—An account is given, preliminary to the consideration of this type of corrosion, of the mechanism of so-called dezincification. The conclusion is reached that true parting of zinc and copper in a 70:30 brass does not occur but that the so-called residual copper is always redeposited copper. Dezincification is therefore only apparent and

not real, and the term is always subsequently employed by the authors in this sense.

The layer type of dezincification, which is characterized by disintegration of the brass tube and redeposition of copper over large areas, has been found to occur under both marine and fresh-water conditions. Several ways in which such action may occur are indicated. Under fresh-water conditions it is often associated with acid water, particularly if the acid is not too dilute and the access of oxygen is not very easy.

Type IV. Plug or Local Dezincification.—This type of local corrosion may be regarded as a form of deposit attack, as it always proceeds beneath a deposit and is stimulated by the presence of foreign bodies. It differs, however, in many ways from Type II. So far as is known it occurs only in sea water (or diluted sea water), and is always associated with adhering white salt consisting of colloidal zinc oxychloride (also containing some carbonate). It is readily reproducible in the laboratory, as it occurs spontaneously on the surface of 70:30 brass tubes after immersion in seawater at elevated temperatures (40 to 50 deg. C.) for a few days; and is hence rather more amenable to experimental study than the previous types of corrosion. It is shown that the production of the right concentration of zinc in the liquid layer adjacent to the corroding brass surface plays a large part in the formation of the characteristic white oxysalt, and that interference with the production of this condition, e.g. by lowering the zinc content of the brass or by raising the zinc content of the sea water, is sufficient to prevent its occurence. The dezincifying action is thought to be due to a small concentration of hydrochloric acid contained within the colloidal white salt. The difference in behavior of different batches of 70:30 tube—some always showing local dezincification, others never—persists after annealing or pickling, or both, and the reason for the difference in behavior is still not clear.

Type V. Water-Line Attack.—In the case of a brass tube only partially immersed in sea water, increased corrosion (compared to that of the immersed portion) takes place, not at the water-line as is commonly supposed, but above it, and sometimes as much as 2 cm. above the surface. Further, the attack is not uniform but is concentrated at areas where salt deposits have formed and is coterminous with the area covered by the deposits. Narrow bands of salt connect the seawater with the deposits. This type of corrosion is obviously a special form of deposit attack, taking place under the most favorable conditions inasmuch as the attack beneath the deposits is much more severe than in any of the previous types of corrosion. This type of attack may occur at the inlet end of condenser tubes when entangled air clings to the surface of the tube and is prevented by eddying effects from being swept away by the water-flow.

The fourth section of the report contains an account of preliminary work on the electrolytic protection of condenser tubes. The particular question investigated was that of the efficiency of electrolytic protection in preventing deposit attack, i.e. attack by cupric chloride solution. A piece of 70:30 brass tube made cathode to strip iron in a normal cupric chloride solution is very distinctly attacked, despite the small current passing from the solution to the brass. It is considered that an electric current slows down but does not necessarily inhibit corrosion of a cathode. By raising the current density sufficiently it is possible that all corrosion even in a cupric chloride solution may be prevented. Experiments have shown, however, that a current as large as 20 to 25 amp. per 1,000 sq.ft. is insufficient to prevent a 70:30 brass tube from being rapidly corroded by such a dilute solution of cupric chloride as a one-twenty-fifth normal solution. Some suggestions are made whereby the usefulness of the electrolytic protection process may be extended by special manipulation of it in the early part of the life of a tube, with the object of forming a thin continuous layer of calcium carbonate over the surface of the tube.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Manufacture of Cement in Electric Furnace.—The ground constituent materials are introduced into an electric furnace the upper part of which consists of a vertical shaft while the lower part contains the electrodes. During their passage through the shaft, the materials are heated and are finally melted in the lower part of the furnace. The molten product is tapped at intervals and cooled suddenly by water or by air. (1,332,422; MAURICE L. BOILLOT and JEAN DAUDIGNAC of Moutiers, France; March 2, 1920.)

Solvent for Acetylene.—The use of cement in the mixture used as fillers for acetylene gas containers is desirable, but the free lime present in the cement reacts with the acetone in an objectionable manner. This difficulty may be avoided by adding to the acetone a quantity of ethyl acetate (or other ester of an organic acid) sufficient to react with the lime in the cement:

$$Ca(OH)_2 + 2CH_3COOC_2H = Ca(OCOCH_3)_2 + 2C_2H_5OH.$$

For example, the filler for a standard acetylene container such as is now used may be composed of:

Portland cement	8 lb. 8 oz.
Kieselguhr	8 lb. 8 oz.
Asbestos fiber	15 oz.
Water	28 lb.
Charcoal	1 cu.ft.

This mixture is introduced into the tank, allowed to harden and thoroughly dried. If the cement contains 1 per cent of free lime, i.e., 1.4 oz., about 3.5 oz. of ethyl acetate should be added to the acetone before adding this to the tank. (1,332,525; HENRY S. SMITH of New York and GEORGE O. CURME, JR., of Pittsburgh, Pa., assignors to the Prest-O-Lite Co., Inc.; March 2, 1920.)

Sulphur Retorts.—In these patents, two retorts somewhat resembling a Kelly filter press in design are described. They consist essentially of a cage into which the sulphur bearing rock is introduced and a housing into which the cage moves when charged. Steam is admitted and the cage rotated. The molten sulphur collects in the shell, from which it is discharged through a valve. (1,332,537; FRANK W. BECRAFT and ALBERT L. GENTER of Salt Lake City, Utah, and 1,332,542; WILLIAM E. CLIFFORD of Salt Lake City and THOMAS H. GREEN of Springfield, Ill.; both assigned to United Filters Corporation; March 2, 1920.)

Sodium Permanganate.—The oxidation of sodium manganate by means of chlorine is catalyzed by the addition of $Co(OH)_3$, which has the additional function of decomposing hypochlorites according to the equation:

$$2NaClO = 2NaCl + O_2$$

Thus, by using an excess of chlorine the free alkali present may be converted into sodium chloride. This prevents decomposition of the permanganate:

$$4NaMnO_4 + 4NaOH = O_2 + 2H_2O + 4Na_2MnO_4$$

Since the formation of hypochlorites and consequently of chlorates is prevented, the solution contains principally sodium permanganate and sodium chloride, which may be separated by crystallization. (1,330,032; ROBERT E. WILSON of Cambridge, Mass.; Feb. 3, 1920.)

Process of Concentrating Liquids.—It is possible to concentrate solutions without heating above 100 deg. F. by adding anhydrous sodium sulphate to the solution heated to the point of maximum solubility of sodium sulphate. Upon cooling crystals of the hydrated salt (Glauber's salt) separate and thus remove a considerable amount of water from the solution. Other anhydrous salts may be employed in the same manner. (1,330,016; GEORGE T. WALKER of Minneapolis, Minn., assignor to Colonial Chemical Co.; Feb. 3, 1920.)

Extracting Thorium From Monazite Sand.—The following procedure is suggested by OTTO N. BERNDT of Chicago: 500 lb. of monazite sand, which has been concentrated by means of a magnetic separator to remove ilmenite and other magnetic constituents and contains about 9 per cent thorium oxide, is treated with about 475 lb. of fuming sulphuric acid stronger than 66 deg. Bé., containing preferably about 5 per cent excess sulphur trioxide. The mixture is heated for a period sufficient to decompose the sands and to convert the thorium into an insoluble compound, the heating preferably being at such a rate that a temperature of 200 to 230 deg. C. is reached in between 3 to 4 hr. At this point the rise in temperature becomes more rapid, due probably to heat evolved by the reacting mass in substantial amounts, attaining a temperature of 300 to 350 deg. C. in from one-half to one hour. The reaction mass becomes greenish-yellow in color and is in stiff plastic state, capable of being further stirred. At this point external heating is stopped and the mass is permitted to cool for several hours while being stirred and is removed from the baking pot or digester. The product is a thick pasty mass weighing about 950 lb. The mass removed from the digesters is treated in suitable tanks with a sufficient quantity of water, preferably about 900 gal. for the above amount. A slight agitation of the solution which has a slight acidity will keep the insoluble thorium compound in suspension, while the heavier siliceous residues will settle to the bottom. The suspension of the thorium compound may be decanted and filtered, the thorium compound remaining as a residue on the filter in a greatly concentrated state and suitable for further purification. (1,329,747; assigned to Lindsay Light Co.; Feb. 3, 1920.)

Production of Cyanides.—This invention relates to an improved form of furnace for carrying out the fixation of nitrogen according to the Bucher process (U. S. Pat. 1,120,682; Dec. 15, 1914.) Briquets are formed of sodium carbonate, pulverized coke or charcoal and finely-divided iron. These are fed into a vertical retort and are treated counter-currently with nitrogen while heated to about 1,000 deg. C. As cyanide is formed, it fuses and binds the briquets together upon reaching the relatively cooler zone below the furnace. Here an eccentric rotating device breaks fragments from the bottom of the column. The broken material passes to a shallow cooler, from which it is delivered at a temperature but little above atmospheric. (1,329,721 and 1,329,722; WILLIAM D. MOUNT of Saltville, Va., assignor to Nitrogen Products Co.; Feb. 3, 1920.)

Cement From Low-Grade Carboniferous Material.—Certain materials such as oil shale, lignite and cannel coal can not be economically used as fuel because of the large amount of fixed carbon which is retained by the argillaceous ash. ROBERT W. LESLEY of Haverford, Pa., has found that this ash is a suitable material for the manufacture of portland cement in combination with calcareous or other ingredients. The carboniferous material is first destructively distilled in suitable retorts, ammonia and other valuable volatile products being recovered from the vapors. The fixed gases assist in heating the kiln referred to later. The ash from the retorts is mixed with limestone and subjected to a clinkering process in a gas or oil fired rotary cement kiln. The fixed carbon in the ash supplies a portion of the heat required in the operation. The hot gases from the kiln serve to heat the retorts for the distillation of further quantities of material. (1,323,294; Dec. 2, 1919.)

Dinitrochlorbenzene and Sulphur Black.—The nitrating agent employed is a mixture of 2,800 lb. H_2SO_4 (66 deg. Bé.) and 610 lb. $NaNO_3$. This is heated to 25 deg. C. in a jacketed cast-iron kettle and 400 lb. of chlorbenzene is added slowly, keeping the temperature between 45 and 50 deg. C. After the total quantity has been added the temperature is allowed to rise to 60 deg. C. The mixture is then heated to 115 to 120 deg. C. until nitration is complete. Upon pouring into water, the dinitrochlorbenzene separates. The product contains about 90 per cent of the 1.2.4 form and 10 per cent of the 1.2.6 form. It may be converted directly into sulphur black without first preparing dinitrophenol: 100 lb. of the product is heated with 500 lb. H_2O and 55 lb. NaOH, forming sodium dinitrophenate. A fused mixture of 210 lb. Na_2S crystals and 102 lb. S is then added and, after an hour, the mixture is heated under pressure for 12 hr. at 120 deg. C. The sulphur black is then precipitated by waste acid from the nitration step. (1,330,074; RICHARD HEYDER of Forest Hills, N. Y., assignor to Williamsburg Chemical Co., Inc.; Feb. 10, 1920.)

Silicon Carbide.—The formation of vapors of silica and silicon during the operation of a carborundum furnace results in an increase in the ratio of silica to carbon in the upper part of the furnace and the product is not uniform. OTIS HUTCHINS of Niagara Falls obtains a uniform product by using a mixture below the resistor core which contains proportionately more silica than that above the core. Thus, the lower portion may contain 100 parts C to 194 parts SiO_2, while the upper portion may contain 100 parts C to 170 parts SiO_2. (1,331,435; assigned to the Carborundum Co.; Feb. 17, 1920.)

Current Events
in the Chemical and Metallurgical Industries

The Shawinigan Industries

A joint meeting of the American Section of the Society of Chemical Industry with the New York Sections of the American Chemical Society and the American Electrochemical Society was held in Rumford Hall on Friday evening, April 9. Dr. H. W. Matheson, general manager, Canadian Electro Products Co., outlined the growth of one of the most interesting and promising electrochemical centers in America—Shawinigan Falls, Que.

Hydro-Electric Developments

Shawinigan Falls is on the St. Maurice River, about twenty-two miles north of the mouth of the river, and about equidistant from Montreal and Quebec. At Shawinigan Falls the river drops 150 ft. and is capable of developing about 250,000 hp. The Shawinigan Water & Power Co. installed two 5,000-hp. waterwheels and generators about 1900. In 1910 the plant had grown to 60,000 hp. and the present capacity is 200,000 hp., the latest installation being five direct-connected generating units, each complete with its double runner horizontal turbine, developing 20,000 hp. at the normal operating head of 150 ft. and a speed of 225 r.p.m.

The St. Maurice valley is one of the finest waterpower sites in the world. Two hundred miles above Shawinigan Falls, the great La Loutre dam (1,800 ft. long, 70 ft. high) impounds the headwaters of the river, forming a lake 360 square miles in area. When full, this reservoir contains enough water to generate one billion kw.-hr. in the existing hydro-electric plants, and thus serves to regulate the power output during periods of low water. Other hydro-electric plants are located at Grand' Mere and Gres Falls, so that the total power developed amounts to about 320,000 hp. at present, with 1,100,000 hp. estimated as the future capacity of the St. Maurice valley.

General Industrial Situation

Of the total power developed, 130,000 hp. is required by the chemical and electrochemical industries at Shawinigan Falls. Among the plants using large quantities of electric power may be mentioned:

The Northern Aluminum Co., which started in 1901 as the Pittsburgh Reduction Co., produces 60 tons of aluminum (pig, wire and cable) per day, using Louisiana bauxite. About 800 men are employed.

The Belgo Canadian Pulp & Paper Co. has a capacity of 165 tons of groundwood pulp, 100 tons of chemical pulp and 90 tons of paper per day.

The Canada Carbide Co. has a plant covering about fifteen acres. The furnaces require about 40,000 hp. and operate on three-phase, 30-cycle and three-phase, 60-cycle power, producing about 200 tons of calcium carbide per day. Coke is obtained from the Montreal Heat, Light & Power Co.

The Shawinigan Electro Metals Co. began operations in 1915 and is now producing magnesium in stick and powder form and is making a careful study of magnesium alloys.

The Canadian Carborundum Co. will soon require 20,000 hp. for the manufacture of carborundum, aloxite and ferrosilicon.

The Canadian Ferro-Alloys Co. uses 6,000 hp. in the preparation of ferrosilicon and ferrochrome.

The Canadian Electrode Co. supplies the other companies with amorphous carbon electrodes.

Acetone From Acetylene

The most interesting portion of Dr. Matheson's paper was devoted to the work of the Canadian Electro Products Co. in producing glacial acetic acid and acetone from acetylene. A brief résumé of the process will be found in Chemical and Metallurgical Engineering, vol. 21, Oct. 29-Nov. 5, 1919, p. 575, and a more detailed discussion will be published at an early date. The process may be divided into five stages:

1. Production of acetylene from calcium carbide.
2. Production of mercuric oxide from mercury.
3. Production of acetaldehyde from acetylene.
4. Oxidation of acetaldehyde to acetic acid.
5. Conversion of acetic acid into acetone.

In the production of acetylene, the carbide was allowed to drop upon aluminum plates in the generators, thereby preventing frictional sparks which might result in explosions. In regard to the second step, the speaker said that the electrolytic oxidation process for the preparation of mercuric oxide had been discarded but no details of the new process were given. Explosions in the brine condensers used in separating the acetic acid formed in step 4 were traced to peracetic acid which is formed at low temperatures in mixtures of air, acetaldehyde and acetic acid.

In conclusion, the speaker predicted a steady growth for Shawinigan Falls as an industrial center, since it can sell power in competition with any country in the world (not excepting Norway and Sweden), is free from labor agitations and is well located for export trade.

Mechanical Engineers' and Chemists' Meeting

On Thursday, April 29, the midcontinent section of the American Society of Mechanical Engineers and the Oklahoma section of the American Chemical Society will hold a joint meeting.

During the morning session the routine business of each section will be attended to and officers for the coming year will be elected. In the afternoon and evening a series of interesting papers will be presented. Among those who have prepared papers are: Dr. C. K. Francis, Cosden & Co., Tulsa; D. E. Foster, Foster & Gilmore, petroleum engineers, Tulsa; Prof. Fred W. Padgett, Oklahoma University, Norman; J. E. Stillwell, Empire Gas & Fuel Co., Bartlesville; Prof. Hilton I. Jones, Oklahoma University, Norman; Arthur Frank, consulting engineer, Tulsa; Mortimer E. Cooley, dean of College of Engineering, University of Michigan; Ernest Hartford, secretary of the A. S. M. E.

Amalgamation, With Special Reference to Steaming of Amalgamation Plates

At the Nov. 15, 1919, meeting of the Chemical, Metallurgical and Mining Society of South Africa a sub-committee consisting of S. H. Pearce and J. E. Thomas reported on the practice of steaming amalgamation plates. In order to get an authoritative opinion questionnaires were sent to all mill-manager members, and the answers, which were received from about half the members to whom questionnaires were sent, were used as a basis for the committee's remarks.

A diversity of opinion exists as to the desirability of steaming; some hold that because of the danger to the health of the workmen the practice should be prohibited, others that it is a necessary operation. The question resolves into one to be considered from the point of saving of labor and the health of the workmen.

Under certain conditions amalgam will accumulate on plates and its removal is laborious unless steam is used to soften the deposit. Depending upon its hardness, the deposit may be removed by scouring or may require the use of chisels. The conditions which affect the quantity and quality of the deposit of amalgam may be roughly divided into two classes, provided such deposits as are allowed to accumulate for the purpose of regulating output are excluded.

Factors Affecting the Class of Deposits

One class of deposits is due to the conditions of the plate—whether hard or soft—the grade or slope of the plate, the frequency of dressing. If a comparatively large amount of amalgam is left on the plate, more mercury can be used in dressing and the plate will remain soft and in good receptive condition longer than a comparatively bare plate under similar conditions. Such plates are scraped lightly and produce when steamed a large return. This method gives a high return by amalgamation with a minimum of labor but holds back gold. A similar condition of the plate may be obtained with the retention of a minimum amount of amalgam, but to obtain this result there are required more frequent dressing, hard scraping every day and probably also a thorough scouring every other day. This results in a high amalgamation return but requires a maximum of labor. Steaming would not be advocated under these conditions. A variation is found in less frequent scouring but in place of steaming a thorough monthly clean-up.

A second class of deposit is due to conditions over which the operator has little, if any, control. These include design of plant and peculiarities of the ore. In the case of a plant with launders of insufficient grade a high water-to-ore ratio is necessary and the plate area is unnecessarily large; on the other hand, modern plants with correct or probably excessive launder grade are economical in plate area. These conditions affect the grade of plate, 18 per cent being necessary in one case and 8 per cent in the latter. Apart from overcrowding of the plate areas, the steeper slope causes difficulty in control of plate condition. With a bare plate there is nothing to overcome the tendency of the mercury to run off the plate and it is necessary to choose between leaving a deposit on the plate and very frequent dressing. In either case the amalgam will harden more rapidly near the top of the plate and its removal will require more labor whether by steaming or by other means.

The degree of alkalinity of the mill water also affects plate accumulation in that an excess of lime hardens the amalgam. In some mills variation in the acidity of the rock make it difficult to regulate the alkalinity, and in these cases a scrape made in the usual way leaves a considerable quantity of amalgam, which may be removed by steaming. The fineness of the gold is also a minor factor. Coarse gold particles produce an amalgam that is easily removed, but the opposite is true where fine particles are present, and these if present in large proportion tend to produce an amalgam containing a higher percentage of gold and show a greater tendency toward accumulation.

Effect of Steaming Amalgamation

Dealing with the facts as they appear, the committee was of the opinion that steaming can be considered only as a means of saving labor, making it possible to remove plate accumulations with the least difficulty, as otherwise in the absence of a mechanical device a large amount of labor would be incurred in most instances.

As regards the effect of steaming amalgamation plates on the health of the workman, there is no doubt that, as with many other ailments, idiosyncracy plays a very large part and certain men suffer from some sort of indisposition after taking part in the operation. In many instances there is probability of mercurial affection, but in at least as many others it is equally probable that the indisposition is due to overexertion and poor health. It seems probable that the practice of eating meals with unwashed hands is far more dangerous as a means of conveying mercury into the system.

The precautions to be observed consist of:

Ample ventilation of plate-houses.

Exhaust steam from plates to be led outside of building.

Selecting men for the work who are known to be immune.

Division of the work to prevent overexertion.

Provision of wash basins, mouth washes, etc.

The report of the committee was followed by a discussion in which members and visitors took part. In the discussion additional points were brought out by those in favor of and opposed to the steaming of amalgamation plates.

List of Commercial Organizations in the United States

A revised edition of a publication that has proved to be a useful desk book among persons engaged in domestic trade has just been issued by the Bureau of Foreign and Domestic Commerce. It is designated Miscellaneous Series No. 99, "Commercial and Industrial Organizations of the United States," and supersedes the first edition issued in 1917. The publication gives the title and secretary's address of practically all active interstate, national, and international commercial organizations, classified both alphabetically and by industry. City commercial organizations are arranged by states, with the address of the secretary and data as to number of members, annual income, and date of annual meeting. The present edition is a complete revision in all particulars, only those associations which made reply to the Bureau's request for information being included.

Washburn's Testimony on Government Nitrogen

Charging that less than 1 per cent of the cost of fertilizer could possibly be given to the farmers as a benefit from operation of the Government plant, even if all the estimated saving could successfully be transferred to the ultimate price of fertilizer, Frank S. Washburn, president of the American Cyanamid Co., opposed before the Senate Committee on Agriculture the War Department's proposal to operate the cyanamide plant at Muscle Shoals. Mr. Washburn objected also to the proposal that the further financing of these plants be accomplished by selling sodium nitrate now held in reserve by the Government.

Criticism of Nitrate Program

Starting on the assumption that nitrates and ammonium compounds are not interchangeable sources of nitrogen for fertilizer or industrial chemical use, Mr. Washburn undertook to demonstrate that we had a large surplus capacity for ammonia production at the present time and that increase in this capacity as proposed for Muscle Shoals would only make it necessary to increase our dependence upon Chile for nitrates. He argued that every increase in the output of ammonia for fertilizer use must be accompanied by a corresponding increase in consumption of nitrates, since otherwise a properly balanced plant food will not be obtained. Mr. Washburn presented a very complete history of the nitrogen fixation developments in this country from the first work in 1907 at the Canadian cyanamide plant through the proposals made to the Government about the same time up to the Muscle Shoals hydro-electric company proposal in 1916. Various recommendations to the Ordnance Department and the Government's committees on nitrogen supply and other activities extending into the first six months of the war period were set forth at length in an attempt to discredit altogether the War Department policies. It was charged that work on the Haber process had resulted simply in wasting $13,000,000 without developing any successful plant or even a successful process. The cyanamide company had placed at the disposal of the War Department convincing evidence that this would be the result, but "the committee did not even accept the offer of the company of these proofs."

No Market for Cyanamide

Mr. Washburn claimed that the results from the cyanamide plant at Muscle Shoals had been 100 per cent satisfactory, the cheapness, purity of the product and capacity of the plant all being greater than expectations. He stated that if this plant had run three years under the contract and the agreements between the War Department and the Air Nitrates Corporation, the Government would have saved not only all of its costs and investment in the plant but a considerable sum in addition. On the other hand, the present result to the company after payment of taxes, losses, etc., is that there is nothing left. He denied that his company was interested in any negotiations to purchase this plant from the Government, as at the present time he believed that the real problem was how to find a market for the product from this plant. Cyanamide nitrogen, characterized as "the cheapest form of nitrogen," is available to the extent which the market now demands in this form, and operation of the Government plant throws upon the market an additional supply to the detriment of private interests, with no advantage to the Government.

Classifying the various sources and kinds of nitrogen for fertilizer supply, Mr. Washburn came to what he considers "the crux of the situation," which is the fact that ammonium sulphate cannot replace sodium nitrate in fertilizers. This is because only the nitrates are assimilated by the plants directly and the ammonia compounds must first be nitrified by bacterial action, which is very slow in the spring of the year when the benefit of fertilizer on plant growth is most important. He also claimed that in other industrial chemical uses the ammonium sulphate should not be regarded as in any sense a possible substitute or source for a substitute of nitrates.

With reference to the manufacture of nitrates at Muscle Shoals, he claimed that even if the plant was fully amortized and that no charge were made for power, yet it would not be a profitable proposition for the Government to continue operations there, as the market is not available for the product. He insisted that $38,000,000 more would have to be spent by the Government to complete the project at Muscle Shoals and that it was altogether out of the question to economically accomplish the additional development necessary under the War Department proposal with present costs.

Alternate Plan Proposed

Asked what alternate plan he proposed, he recommended that the plant be kept in condition ready for use in production of explosives in case of war, and that the Government hold itself in readiness to sell the plant to private interests whenever market conditions justified this. He insisted that no one would be willing to buy the plant at the present time but that the plant would probably not become obsolete in the near future, as the processes and equipment were already too fully standardized to permit this.

Estimated Requirements of Fixed Nitrogen

The charts which were presented to support the above conclusions were based upon projecting the normal increases in demand for nitrate and ammonia before the war up to 1930. For this latter year Mr. Washburn estimates a demand for 875,000 tons of sodium nitrate, 775,000 tons of ammonium sulphate or its equivalent in cyanamide and that surplus ammonia capacities would be available as follows: (*a*) assuming only a normal increase in pig iron production, 125,000 tons of ammonium sulphate surplus; (*b*) assuming that one-half the beehive ovens were converted to byproduct ovens an additional 165,000 tons of ammonium sulphate; (*c*) assuming full conversion from beehive to byproduct ovens a still further amount of 165,000 tons ammonium sulphate per year, and finally, (*d*) assuming that the Government Muscle Shoals plant is operated, 200,000 tons of ammonium sulphate additional surplus. The total demand and surplus thus estimated for 1930 are 2,325,000 tons computed as ammonium sulphate equivalent. Another chart estimated the world nitrogen resources in 1919 as 1,500,000 tons of nitrogen, of which about 900,000 tons finds ready market, the remainder being surplus capacity. This surplus capacity is shown by the charts as just equivalent to the sum of the capacities of the Haber and the cyanamide processes, which are given as 300,000 tons each per year. Projecting this curve to 1930, it was estimated that the demand for nitrogen in that year would amount to 1,280,000 tons of nitrogen, which is less than the present capacity for nitrogen production as estimated.

Portland, Oregon, a Shipping Point for Phosphate Rock

To facilitate the shipment of phosphate rock in bulk from the United States to Japan, Portland is erecting bunkers with a capacity of 20,000 tons, on its newest municipal terminals. These will be completed late in July or early in August. The new bunkers are to be equipped with mechanical conveyors for unloading the rock from the cars, in which it is brought from Idaho, into the storage bins. It is then loaded directly into ships for ocean transportation. The bunkers will be capable of loading a vessel of any size with a full cargo in one day.

Portland had an advantage over Seattle in a differential of one dollar in the rail rate from the producing center to the seacoast. The advantage of Portland over San Francisco lay in the fact that lumber is desired for shipment in part cargo lots with phosphate rock to balance the cargoes. As rock is exceedingly heavy, a vessel loaded with it alone would be down to the load line before all her cargo space was filled. It is held, therefore, that the ideal cargo is a combination of about 4,500 tons of rock and enough lumber to fill the hold. Lumber for export to the Orient is available at Portland in almost unlimited quantities.

Phosphate rock, consisting largely of calcium phosphate, is in great demand in Japan. Furukawa Co., Ltd., of Kobe, Japan, which has booked the largest amount to date for export, controls several large plants in Japan for crushing the rock and converting it into superphosphates.

Chemical Activities at Yale University

At present all the chemical work of the Academic Department and Sheffield Scientific School are consolidated under one head, thus doing away with much duplication of courses and equipment.

Plans are now under consideration to build a centrally located chemical laboratory to take care of the needs of the entire university. It is planned to build the new laboratory large enough so that all of the courses can be carried on under the same roof. Special emphasis will be given to the industrial side of chemistry, and the new laboratory will be well equipped for this purpose.

In order to further the work of organic chemistry in its application to the industries, a series of lectures by the following men has been arranged, for the students of this year: Dr. C. L. Reese, research director, E. I. du Pont de Nemours & Co.; Dr. C. G. Fink, head of research laboratory, Chile Exploration Co.; Dr. W. S. Landis, chief technologist, American Cyanamid Co.; Dr. Hyle, research director, Upjohn & Co., Kalamazoo, Mich.; Dr. C. R. Downs of The Barrett Co., Dr. C. O. John of the Bureau of Chemistry, Washington, D. C.

Exhibition of American Products in Buenos Aires

A cablegram from Commercial Attaché Julius Klein, at Buenos Aires, states that the American Chamber of Commerce in that city has requested the American National Expositions, Inc., to hold its proposed exhibition of American products in November and December of 1920 instead of March, 1921. This request has been agreed to, according to information received from the directors of American National Expositions, Inc.

War Department Releases Sodium Nitrate

An indication of the seriousness of the shortage of fertilizer raw materials was the action of the Senate on March 31 in allowing the immediate consideration and passage of a bill authorizing the Secretary of War to lend soda to fertilizer distributers or users. The rules of the Senate require that a resolution of that character must be referred to a committee. In this case the Committee on Agriculture had jurisdiction.

Quite contrary to custom the committee agreed immediately to report the bill favorably and the measure was passed without a dissenting vote. The text of the resolution is as follows:

> That in order to meet the existing emergency in the shortage of fertilizers, the Secretary of War is hereby authorized to turn over to agricultural fertilizer distributers, or users in this country, such quantity of nitrate of soda held as a reserve supply by the War Department as in his opinion can be spared consistently with the military needs of the Government, such stocks so turned over to be replaced by such fertilizer distributers or users with an equivalent amount of nitrate, the turning over and replacement being under such guarantees as the Secretary of War may prescribe.

The resolution had been approved prior to its introduction by both the War and Agricultural Departments.

Oil-Shale Plant to Locate at De Beque

The Shale Oil & Refining Co. of New York City has recently signed a contract with the Gas Machinery Co. of Ohio for the equipment of the first unit of a plant to produce gasoline from shale. The company has a large tract of oil-shale lands in Colorado, and is planning to erect its plant at De Beque, Col., to distill the shale. A contract is to be placed next month for a refinery.

The first unit will handle from 300 to 400 tons of shale per day which, it is estimated, will yield about 300 to 400 bbl. of oil. The Wallace process of distillation will be used, and eight retorts are to be installed. The plant is expected to be in operation about next September, and it is estimated that it will cost in the neighborhood of $250,000.

This is the first attempt to utilize the oil shales in this country on a commercial scale, and with the demand for oil ever on the increase this development will be watched with much interest.

Research on Alunite

The metallurgical research department of the Utah State School of Mines, in co-operation with the U. S. Bureau of Mines, has been doing considerable work recently on the massive low-grade alunite deposits from Piute County, Utah. Experiments have been made with the idea of economically obtaining potash from the ores by a simple roasting-lixiviation process. The object of the tests is to determine:

1. The roasting temperature best adapted to a high recovery of potash by subsequent lixiviation.

2. The size of crushed ore which on roasting at the most desirable temperature gives the best extraction-crushing economy combination.

3. Whether there is a loss of potash by volatilization during roasting operations.

Further tests on a large scale are now under way. These tests are to be carried on with the object in view of recovering the alumina as well as the potash.

Meeting of Electric Furnace Association

The Electric Furnace Association held a meeting at the Massachusetts Institute of Technology on April 8 at which the subject of adequately trained electric furnace operators was discussed. The symposium was led by Acheson Smith, president of the Association, who pointed out the tremendous growth of the electric steel industry, and the inability of steel producers to get a sufficient supply of trained electric furnace operators. The number of electric furnaces operating in the United States and Canada has increased from 22 in 1913 to 363 in 1920. The weight of electric steel castings has increased from 9,207 gross tons in 1913 to 108,296 gross tons in 1918. The following table shows the comparative production of crucible and electric steel in the United States and the growth of electric steel since 1913:

Year	Production of Steel Ingots and Castings by Crucible Process, Gross Tons	Electric Furnace, Gross Tons
1913	121,226	30,180
1914	89,869	24,009
1915	113,782	69,412
1916	129,692	168,918
1917	126,716	304,543
1918	115,112	511,364

The figures for alloy steels for the year 1918 may also be of interest:

Process	Ingots, Gross Tons	Castings, Gross Tons	Total, Gross Tons
Open hearth—basic	1,013,913	10,724	1,024,637
Open hearth—acid	323,913	29,191	353,104
Bessemer converter	41,286	23,430	64,716
Crucible steel	54,370	64	54,434
Electric steel	287,885	3,076	290,961
Total	1,721,367	66,485	1,787,852

"The possibility of using the electric furnace in the production of brass and other non-ferrous metals has just begun to be appreciated, and it is only recently that a considerable number of electric furnaces have been used in this field. At the beginning of 1919 there were possibly fifty-eight electric furnaces producing brass, while at the beginning of 1920 there were at least 146 electric furnaces engaged in this work. The results already accomplished indicate that the application of the electric furnace in this field has been highly successful and the demand for more furnaces will follow rapidly."

Demand for Skilled Melters

This great increase in the use of electric furnaces has led to an unsupplied demand for skilled melters and assistants. Discussion of Mr. Smith's paper developed the fact that colleges and universities could not be expected to supply this demand, for it is not their function to turn out men skilled in operating details. It appears to devolve on the electric-steel industry to train its own personnel from either technical graduates or intelligent skilled labor; or upon the manufacturers of electric furnaces to furnish service to the metal industries in the form of men trained by the manufacturers themselves. In the latter case the Electric Furnace Association might take official action in the establishment of a training school.

Officers Elected

Officers of the Association for the ensuing year were elected as follows: President, Acheson Smith; vice-presidents, C. H. Booth and H. L. Hess; secretary, C. G. Schluederberg; treasurer, F. J. Ryan; directors for two years, F. J. Tone and H. G. Weidenthal.

Personal

James Bradley, formerly of the Atlas Powder Co., is plant supervisor of the Du Pont dye and intermediate plant at Lodi, N. J.

Dr. Benjamin T. Brooks is chemical engineer for the Mathieson Alkali Works, with headquarters at the newly established New York office, 25 West 43rd St.

W. E. Burkhard, formerly chief chemist of the Baker-Adamson Co., is chemical engineer at the Perth Amboy Chemical Works.

A. S. Eastman has been placed in charge of chemical control at the Calco Chemical Co., Bound Brook, N. J.

Prof. Ralph H. McKee, of Columbia University, has been consulting with officials in Washington on various chemical matters.

Edwin Mullen, returning from the Army, has been made superintendent of the Camden Works, General Chemical Co.

Walter B. Murphy has been transferred from the Frankford plant of The Barrett Co. to the main offices in New York, where he will take up his new duties as manager of industrial relations.

H. C. Parmelee, editor of Chemical & Metallurgical Engineering, left New York April 7 for an extended trip. He attended the spring meeting of the American Electrochemical Society in Boston and is attending the meeting of the American Chemical Society in St. Louis, Mo. From there he will go west to Omaha, Denver, Salt Lake City and San Francisco. He expects to be gone about two months.

Dr. Charles L. Parsons, secretary of the American Chemical Society, will sail shortly for Europe. He expects to attend the meeting of the International Union of Pure and Applied Chemistry, which will be held in Rome in June. In addition he will visit a number of chemical plants in Italy, Switzerland, France, Belgium, Germany and England.

Charles F. Rand was elected chairman of the Engineering Foundation at a special meeting held March 25. He succeeds Dr. W. F. M. Goss, resigned.

W. Kilburn Scott was a recent caller at the nitrate division of the War Department in Washington.

Obituary

Arthur L. Ormay, illustrator-in-chief of the McGraw-Hill Co., died at his home in Brooklyn, March 23. Mr. Ormay was born in Hungary, May 25, 1881. After the usual preliminary education he entered the Polytechnic of Budapest, from which he was graduated in June, 1905, with the degree of M.E. He came to the United States the following year and shortly afterward joined the staff of *Engineering News* as draftsman and letterer. He stayed with this paper for about three years. He then went to John Hill with a proposal to establish a drafting department to do the work of the papers of the Hill group, which at that time consisted of the *American Machinist, Power,* and *Engineering and Mining Journal.* The consolidation of the McGraw and the Hill companies in 1917, after Mr. Hill's death, broadened Mr. Ormay's duties and responsibilities, as he then had ten technical papers to serve. He was given the title of illustrator-in-chief, which he held at the time of his death.

In addition to his other talents, Mr. Ormay was noted for his pen-and-ink sketches of persons. One of his best was a large likeness of Mr. Hill, which was finished shortly before Mr. Hill's death. This portrait displays an execution and artistic talent of a very unusual quality.

Current Market Reports

The Non-Ferrous Metal Market

New York, April 12, 1920—There have been few changes since last week.

	Cents per Lb.
Copper, electrolytic	19.25
Aluminum, 98 to 99 per cent.	32@33
Antimony, wholesale lots	11.25
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	62.25
Lead, New York, spot	9.00
Lead, E. St. Louis, spot	8.75
Zinc, spot, New York	9.00
Zinc, spot, E. St. Louis	8.60

OTHER METALS		
Silver	oz.	$1.26
Cadmium	lb.	1.40@1.50
Bismuth (500 lb. lots)	lb.	2.50
Cobalt	lb.	1.50
Magnesium (f.o.b. Niagara Falls)	lb.	1.60
Platinum	oz.	142.00
Iridium	oz.	250.00
Palladium	oz.	142.00
Mercury	75 lb.	103.00

FINISHED METAL PRODUCTS	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled, (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	26.75
High brass wire and sheets	26.50
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	34.00
Seamless bronze tubing	34.50
Seamless high brass tubing	33.00

SCRAP METALS	Cents per Lb. Buying Price
Aluminum, cast scrap	22.00@23.00
Aluminum, sheet scrap	21.50@22.75
Aluminum clippings	24.75@26.00
Copper, heavy machinery comp.	14.25@14.75
Copper, heavy and wire	14.25@14.50
Copper, light and bottoms	13.00@13.50
Copper, heavy cut and crucible	15.50@15.75
Brass, heavy	9.50@10.00
Brass, casting	9.00@ 9.25
Brass, light	9.00@ 9.25
No. 1 clean brass turnings	8.75@ 9.25
No. 1 comp. turnings	11.25@11.50
Lead, tea	5.75@ 6.00
Lead, heavy	7.75@ 8.00
Zinc, scrap	5.25@ 5.75

The Iron and Steel Market

Pittsburgh, Pa., April 9, 1920.

The outstanding feature of the iron and steel market situation is the wide variety of opinions held by those in the trade both as to the actual condition today and as to the prospects. The condition as to production, which is large, is held in some quarters to indicate that prices must decline, and in other quarters to prove that steel will be still scarcer when expected additional demand develops. As to the future, not merely of steel but of industry generally, there are those who predict a "panic," though precisely what is meant by the term is not defined, next August or September, there are others who predict something of the sort a year hence, or some time in 1921, and still others who insist there is no basis for predicting any panic at all, except that if one lives long enough he is likely to see almost anything.

The monthly steel ingot report of the American Iron and Steel Institute shows that in March 3,296,799 gross tons of steel ingots were produced by thirty companies which in 1918 made 84.03 per cent of the country's total. Counting the number of working days in the month and year and allowing for the producers not reporting, this indicates that during March steel ingots were produced at the rate of 45,200,000 tons per annum. Similarly indicated rates were 44,200,000 tons in February and 40,650.000 tons in January. For the last four months of 1919 no monthly reports were made. Even the January output was larger than had been expected in December, and the increase from January to March was 11 per cent.

The manufacturing difficulties that were foreseen in December—shortage of coke and coal, winter weather, etc.—were all experienced, and the works probably did not operate at much higher percentages of their capacity than had been expected, but it now appears that capacity of the industry as a whole was underrated, and this means that the March production rate can be improved upon very materially. Until quite recently the country's steel ingot capacity was regarded as being 49,000,000 to 50,000,000 tons, according to estimates quite generally accepted. On this basis, however, the March production, with all the obstacles to efficient operation, would be more than 90 per cent of capacity. The disposition now is to regard capacity, under favorable working conditions, as nearer 55,000,000 tons. On a 55,000,000-ton rating the March output would be 82 per per cent of capacity, and that seems to be too low a percentage, in view of the conditions, just as 90 per cent seems too high.

Outlook Good for Fullest Employment of Steel Mills

Shipments of finished steel products from mills were slightly in excess of the production, as a little progress was made toward reducing the large accumulations of January and February caused by car shortage. Receipts by consumers were in turn heavier than shipments, because belated shipments were arriving. Thus the receipts of steel were very large indeed. All the surface indications are that the steel was all absorbed and passed into actual ultimate consumption. If that really was the case, there are very strong probabilities that steel will be as scarce in future as of late, if not scarcer, for it was common everyday consumption that absorbed the great bulk of the steel. Very little steel went to railroads and relatively little went into large construction works. In future it is quite certain the railroads must have much more steel, and certainly there will be much more steel, eventually, consumed in construction work. From this viewpoint the outlook is for the fullest employment of steel mills for a long time to come, and for the minimum prices now asked, those of the Steel Corporation, to rise, even though the maximum prices, now secured for early deliveries, may fall part of the distance by which they are separated from the minimum prices.

The experience of a few weeks, however, can hardly be accepted as sufficient to prove the case, especially when the case is such an important one. When steel was so extremely scarce for several months, a few weeks of heavy shipments without a surplus becoming visible is hardly a sufficiently long experiment. It is said that jobbers and manufacturing consumers have up to date accumulated no stocks, but there has hardly been time for a trustworthy canvass to be made, if indeed trustworthy information could be secured in all quarters. Nor would the absence of stocks in the hands of manufacturing consumers prove the entire case. Many of them make goods that are in turn handled by jobbers and retailers, whose stocks likewise have been low and may be in process now of being built up. The household, the carpenter's shop, the contractor's history, may have been getting material long desired.

In view of these considerations there are those in the steel trade who now argue that when so much steel can be made, and is being pushed out into business, a relaxation in the pressure of buyers will quite possibly occur at an earlier time than the broader demands, of railroads and investment builders, are expressed in actual orders. The one might occur in a few weeks, the other might not come for months, perhaps not until next year.

The American Sheet & Tin Plate Co. announces that early next week, presumably about Tuesday, it will open its order books for second half business in the case of manufacturing consumers and third quarter in the case of jobbers, at the following prices: Blue annealed sheets, 10 gage, 3.55c.; black sheets, 28 gage, 4.35c.; galvanized sheets, 28 gage, 5.70c.; 100-lb. tin plate, $7 per base box, Pittsburgh, plus rail freight to destination. These are the prices in the Industrial Board schedule that became effective March 21, 1919. The Steel Corporation subsidiaries have adhered to that price schedule in all particulars, and a fresh evidence is now afforded, though none was needed, that the

corporation has no intention of departing from its well-known policy as to prices.

As was the case with contracts for the present half year, the independent tin plate manufacturers in general will probably sell at the $7 price. The independent sheet manufacturers, with perhaps an occasional exception, now show no disposition whatever to observe the Steel Corporation prices. They have been selling up to date at a variety of prices, depending upon tonnage, time of delivery and the standing with the producer of the buyer. With nearly all mills the regular customer gets a lower price than the casual or chance buyer. Roughly speaking, prices of independent sheet manufacturers run from ½c. a lb. to 3c. or 4c. a lb. above the basis prices. The independents will sell only short distances ahead, as formerly.

Pig Iron

Substantially all the Connellsville furnace coke available for April has been disposed of, either by direct sales or by price adjustment under contracts calling for a monthly settlement. Except for two or three early transactions the coke has brought $11@$12, the Government limit ruling to the end of March having been $6. The high coke market has served to stiffen the position of merchant furnaces, but at the same time there has been little demand for pig iron. The valley market is quotable steady but quiet at former figures: bessemer, $42; basic, $41.50; foundry, $42, f.o.b. valley furnaces, freight to Pittsburgh being $1.40.

Ferro-Alloys

Ferromanganese for second quarter is firm at a minimum of $180, delivered, some producers quoting $200, while early deliveries command up to about $250. English is quoted at $200, c.i.f. Spiegeleisen continues to stiffen, being now quotable at $62 to $62.50, furnace, for spot, 19 to 21 per cent. Electrolyic ferrosilicon is held at $80, delivered, for 50 per cent and at $140 for 75 per cent. Bessemer ferrosilicon quotations are unchanged at $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. furnaces at New Straitsville and Jackson, Ohio.

The Chemical and Allied Industrial Markets

New York, April 12, 1920.

The tendency of these markets continues upward, especially in the alkalis and heavy chemicals. The coal-tar products are generally firm, owing to the scarcity of material in practically all lines. The present dock strike has crippled the spot market, which even before this trouble was in a bad way. No decline is foreseen for some time to come, particularly with the shortage of steel containers and the poor transportation facilities to be faced. This does not imply that if these conditions were more ideal the situation would be easier, for producers are unable to get the same percentage of production out of the same materials as they were formerly and output has fallen far behind the demand. The cost of labor alone in the production of most of the listed chemicals would be almost sufficient to maintain the present price levels.

PRINCIPAL PRICE CHANGES

	Today	Last Week	Last Month	Last Year
Alcohol, methyl	$3.50	$3.50	$2.50	$1.50
Barium chloride	180–200	140–150	160–170	76–80
Soda ash, light	2.75	2.50	2.50	1.50
Soda ash, dense	3.00	2.75	2.75	2.25
Sodium hydroxide	6.00	6.50	5.25	2.50
Sodium nitrite	.27	.30	.60	.17

General Chemicals

Under pressure of heavy demand and small supplies *alum, ammonia lump,* has been well sustained at 4@5c. per lb., while *potash lump* is fairly active at 7½@8½c. per lb. on contract. There were some small quantities of *ammonium sulphate* being sold on back contracts at 6c. per lb., but these have been filled and the present quotation ranges from 7@8c. Both grades of *sal ammoniac* remain practically nominal, as there is no material available on the spot market at present. *Oxalic,* crystals, has come up, being listed at 44@45c. per lb. for future and as high as 48c. is being asked for spot material. Stocks on this item are not dangerously low, but producers are having difficulty in keeping up with the present brisk demand. *Barium chloride* is tighter than it has been since the rapid rise of a week ago. Some material is changing hands in small lots and prices as high as $200 per ton are being asked for spot. A shipment is expected to arrive in this market soon, which ought to break the present high level. The Association price on *caustic soda* has been raised again recently to $4.50@$5.50 per cwt. But this is no indication of the market, as business is being transacted on a $6@$6.50 basis, with even higher prices reported for spot material. *Sodium nitrite* has come up again slightly and is now listed at 33@35c. per lb. for spot material. One large handler of this item is awaiting the arrival of a shipment and will sell at 22c. per lb. *Soda ash* is practically off the market, as there is no material to be had on the spot market and producers are so far behind in their contracts they cannot take any more business at present. Prices are nominal at $3.25@$3.50 per cwt. It is reported that manufacturers are sold out and refuse to quote on *sodium sulphide,* 60-62 per cent fused, prices ranging from 7@7½c. for future and 8@8½c. per lb. for spot, are nominal. The brisk demand on *copperas* has nearly exhausted the market of this item, and producers are unable to meet the demand. Quotations of $1.50@$2 per cwt. are practically nominal.

Coal-Tar Products

This market remains practically unchanged, prices being sustained in all lines by scarcity of material. Demand is heavy and producers are unable to take care of all the business and are falling behind in their contracts. Spot market activity is confined to the scarcer items on the list, with only small quantities changing hands at extreme prices. To add to this the material in the hands of dealers is nearly exhausted and according to those engaged in this line there is no relief in sight.

Cresylic acid, 97-99 per cent, held firm at the former high level of 95c.@$1.10, while 50 per cent is still listed at 60@70c. per gal. *H* acid is still unobtainable except in small lots which are being sold as high as $1.90@$2 per lb. There is very little *napththionic* acid, crude, to be had. Prices are firm at the former levels of 65@85c. per lb. *Dimethylaniline* is still off the market. No quotations were heard, as there is no material being offered. *Nitrobenzol* is nominally listed at 14@19c. per lb., but there is very little material available at these prices and producers are completely sold out. *Paratoluidine* is in the same position, spot prices ranging from $2@$2.50 per lb.

Waxes

This market is in practically the same position as it was a week ago. Interest has fallen off slightly in refined *beeswax,* dark, which dropped from 39@40c. to 38@39c. per lb. Large supplies of Japan grade are reported in the primary market, but buyers seem fairly supplied, a condition that has held this grade in the same position as was previously reported, 19@20c. per lb. being the quotation received.

Crude Rubber

The recent jump in exchange has steadied this market to some extent. Dropping prices have stopped and quotations remain at the levels previously reported. As yet buyers have not come back into the market due to a large extent to difficulty in obtaining tire fabric, which has considerably restricted the output of this industry. *Plantation* grades are listed as follows: *First latex,* 47½@48½c.; *brown crepe,* thin clean, 45c., and ribbed smoked sheets, 37@48c. per lb., with little trading in sight.

Vegetable Oils

This market has been generally weak during the period, there being very little activity evidenced. *Linseed oil,* raw, in car lots, came up from $1.74 of a week ago to $1.84, while boiled, in car lots, is listed at $1.87 per gal. for May and June. Prices ranging from $1.65@$1.70 for July-December delivery have been heard during the period. Other oils have been quiet, prices remaining firm with very little actual business transacted.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0.60 – $0.65
Acetone	lb.	$0.13 – $0.15	.16 – .18

Sodium borate (borax)	lb.	.08¼ – .08½	.09 – .09½
Sodium carbonate (sal soda)	100 lb.	1.60 – 1.80	1.80 – 2.00
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	4.50 – 5.50	6.00 – 6.50
Sodium hyposulphite	lb.	—	.03 – .04
Sodium molybdate	lb.	2.50 –	3.25¼ –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.26 – .27	.33 – .35
Sodium peroxide, powdered	lb.	—	.30 – .32
Sodium phosphate, dibasic	lb.	.03½ – .04½	.04¼ – .05
Sodium potassium tartrate (Rochelle salts)	lb.	.39 – .40	.40 – .41
Sodium prussiate, yellow	lb.	.23 – .z	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01½ – .02	.02 – .02½
Sodium silicate, solution (60 deg.)	lb.	.02½ – .03	.04 – .05
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.15 – 1.40	1.60 – 2.00
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	.07 – .07½	.08 – .08½
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05½ –	.06 –
Sulphur, crude	ton	22.00 –	—
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –	.46 – .50
Tin oxide	lb.	.50 – .60	.65 –
Zinc carbonate, precipitate	lb.	—	.19 – .20
Zinc chloride, gran	lb.	.13 –	.13½ – .15
Zinc cyanide	lb.	.49 –	.50 – .60
Zinc dust	lb.	.11½ – .12½	.13 – .15
Zinc oxide, U. S. P	lb.	—	.19 – .21
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 — $1.10
Alpha naphthol, refined	lb.	1.40 — 1.60
Alpha naphthylamine	lb.	.40 — .50
Aniline oil, drums extra	lb.	.34 — .45
Aniline salts	lb.	.42 — .48
Anthracine, 80% in drums (100 lb.)	lb.	.90 — 1.00
Benzaldehyde (f.f.c.)	lb.	2.00 — 2.10
Benzidine, base	lb.	1.25 — 1.35
Benzidine, sulphate	lb.	1.20 — 1.25
Benzoic acid, U.S.P	lb.	90 — 1.10
Benzoate of soda, U.S.P	lb.	.80 — 1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 — .36
Benzol, 90%, in drums (100 lb.)	gal.	.25 — .31
Benzyl chloride, 95-97%, refined	lb.	.35 — .40
Benzyl chloride, tech	lb.	.25 — .35
Beta naphthol benzoate	lb.	.50 — .65
Beta naphthol, sublimed	lb.	.70 — .90
Beta naphthol, tech	lb.	.45 — .55
Beta naphthylamine, sublimed	lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 — 1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85 — 1.00
Cresylic acid, 50%, first quality, drums	gal.	.60 — .70
Dichlorbenzol	lb.	.08 — .10
Diethylaniline	lb.	1.40 — 1.50
Dimethylaniline (nominal)	lb.	—
Dinitrobenzol	lb.	.30 — .37
Dinitroclorbenzol	lb.	.25 — .30
Dinitronaphthaline	lb.	.45 — .55
Dinitrophenol	lb.	.34 — .36
Dinitrotoluol	lb.	.40 — .45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 — .40
Diphenylamine (nominal)	lb.	.55 — .65
H-acid (nominal)	lb.	1.90 — 2.00
Metaphenylenediamine	lb.	1.15 — 1.80
Monochlorbenzol	lb.	.10 — .12
Monoethylaniline	lb.	1.70 — 1.85
Naphthaline crushed, in bbls. (250 lb.)	lb.	08 — .09
Naphthaline, flake	lb.	.09 — .10
Naphthaline, balls	lb.	.10½ — .11
Naphthionic acid, crude	lb.	.70 — .85
Nitrobenzol	lb.	.14 — .19
Nitro-naphthaline	lb.	.40 — .50
Nitro-toluol	lb.	.20 — .30
Ortho-amidophenol	lb.	3.75 — 4.25
Ortho-dichlor-benzol	lb.	.15 — .20
Ortho-nitro-phenol	lb.	80 — 1.25
Ortho-nitro-toluol	lb.	.25 — .40
Ortho-toluidine	lb.	25 — .45
Para-amidophenol, base	lb.	2.50 — 3.50
Para-amidophenol, HCl	lb.	2.50 — 3.25
Para-dichlor-benzol	lb.	08 — .12
Paranitraniline	lb.	1.00 — 1.35
Para-nitro-toluol	lb.	1.35 — 1.50
Paraphenylenediamine	lb.	2.60 — 3.00
Paratoluidine	lb.	2.00 — 2.50
Phthalic anhydride	lb.	65 — .75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	12 — .25
Pyridin	gal	2.00 — 2.50
Resorcin, technical	lb.	4.25 — 4.50
Resorcin, pure	lb.	6.25 — 6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.50 — .52
Salicylic acid, U. S. P.	lb.	.55 — .60
Salol	lb.	.90 — 1.00

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.25 —	$0 31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.38 —	$0.39
Beeswax, refined, light	lb.	.40 —	.41
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	.80 —	.88
Carnauba, No. 2, regular (nominal)	lb.	.60 —	.70
Carnauba, No. 3, North Country (nominal)...†	lb.	.43 —	.45
Japan	lb.	.19 —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	..... —	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.11
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.10¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.11 —	.11¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.12 —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.13½ —	.14
Stearic acid, single pressed	lb.	.26 —	.27
Stearic acid, double pressed	lb.	.32 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist.	gal.	.....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.38
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.95 —	$19.50
Rosin E-I	280 lb.	19.75 —	20.00
Rosin K-N	280 lb.	20.25 —	21.95
Rosin W. G.-W. W.	280 lb.	22.00 —	24.00
Wood rosin, bbl.	280 lb.	15.50 —	18.50
Spirits of turpentine	gal.	..... —	2.30
Wood turpentine, steam dist.	gal.	..... —	2.75
Wood turpentine, dest. dist.	gal.	..... —	2.00
Pine tar pitch, bbl.	200 lb.	8.40 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	15.00
Retort tar, bbl.	500 lb.	15.00 —	15.50
Rosin oil, first run	gal.	.92 —	.95
Rosin oil, second run	gal.	.94 —	.97
Rosin oil, third run	gal.	1.10 —	1.15
Rosin oil, fourth run	gal.	1.17 —	1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.40½ —	$0.42
Upriver coarse	lb.	.30½ —	.32
Upriver caucho ball	lb.	.32½ —	.33
Plantation—First latex crepe	lb.	.47½ —	.48½
Ribbed smoked sheets	lb.	.47 —	.48
Brown crepe, thin, clean	lb.	.45 —	.....
Amber crepe No. 1	lb.	.46 —	.47

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19 —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.23
China wood oil, in bbls.	lb.	.24¾ —	.25¼
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18½ —	.19
Cocoanut oil, Cochin grade, in bbls.	lb.	.19½ —	.20
Corn oil, crude, in bbls.	lb.	.17¾ —	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½ —	.18
Cottonseed oil, summer yellow	lb.	.18½ —	.19
Cottonseed oil, winter yellow	lb.	.21 —	.23
Linseed oil, raw, car lots	gal.	1.84 —	.....
Linseed oil, raw, tank cars	gal.	1.77 —	.....
Linseed oil, boiled, car lots	gal.	1.87 —	.....
Olive oil, commercial	gal.	2.50 —	3.00
Palm, Lagos	lb.	.16 —	.16½
Palm, bright red	lb.	.15¾ —	.17½
Palm, Niger	lb.	.15 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.20½ —	.22
Peanut oil, refined, in bbls.	lb.	.27 —	.28
Rapeseed oil, refined, in bbls.	gal.	1.64 —	1.70
Rapeseed oil, blown, in bbls.	gal.	1.64 —	1.68
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19 —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.15½ —	.16

FISH

Winter pressed Menhaden	gal.	$1.17 —	$1.18
Yellow bleached Menhaden	gal.	1.20 —	1.22
White bleached Menhaden	gal.	1.23 —	1.24
Blown Menhaden	gal.	1.30 —	1.35

† (See New York market letter)

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$38.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.04½ —	.05½
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	—	..
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	.04½ —	.06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar (nominal)	ton	13.50 —	18.00
*Fluor spar, acid grade, lump, f.o.b. mines	net ton	30.00 —	45.00
*Fluor spar, acid grade, ground, f.o.b. mines	net ton	55.00 —	65.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00

Graphite, crucible, 91% carbon content	lb.	..... —	.10½
Graphite, crucible, 92% carbon content	lb.	..... —	.11
Graphite, crucible, plus 92%	lb.	..... —	.12½
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, orange, fine, nominal	lb.	1.45 —	
Shellac, orange, superfine	lb.	1.60 —	1.65
Shellac, A. C. garnet	lb.	1.30 —	1.35
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	20.00 —	60.00
Talc, imported	ton	60.00 —	70.00

*Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.22
Ferro-manganese, 70-80% Mn.	gross ton	180.00 —	240.00
Spiegeleisen, 16-20% Mn.	gross ton	60.00 —	65.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.25 —	2.75
Ferro-silicon, 50%	gross ton	80.00 —	90.00
Ferro-silicon, 75%	gross ton	150.00 —	200.00
Ferro-silicon, 10-15%	gross ton	60.00 —	65.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90 —	1.10
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	6.50 —	7.50

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	.....
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	.....
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	14.00
Fluor spar, gravel, f.o.b. mines	net ton	25.00 —	30.00
Manganese ore, 45% Mn and over	unit	.75 —	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00 —	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00 —	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50 —	7.50
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

*Government prices.

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage: for galvanized corrugated sheets, add 15c., all gages.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Dixie Brass & Fdry. Co., 6th Ave. North, between 12th and 13th Sts., is in the market for portable electric welding outfits, lathes, drill presses, and general machine shop, iron and brass foundry tools and equipment.

California

EL MONTE—The city has awarded the contract for the construction of a sewer system and Imhoff septic tank, to McNeil & Barnett, 234 South Center St., Orange, at $41,813. Noted March 17.

OAKLAND—The Palmolive Co., 42 4th St., Milwaukee, Wis., is having plans prepared for the construction of an oil mill. Estimated cost, $500,000. Lockwood, Greene & Co., 38 South Dearborn St., Chicago, engrs. Noted March 3.

SACRAMENTO—The Southern Pacific Ry. Co., 65 Market St., San Francisco, is having plans prepared for the construction of a brass foundry, here.

SAN FRANCISCO—The Natl. Carbon Co., Brannan and 8th Sts., has awarded the contract for the construction of a 4-story, 175x275-ft. warehouse, etc., to Hannah Bros., 142 Sansome St., at $362,500.

WILMINGTON—The Vegetable Oil Products Co., Wilmington, Del., is negotiating for a site upon which to build a refinery, the first unit of which will cost about $300,000. Edward G. Mueller, dir.

Connecticut

BRIDGEPORT—The Harvey Hubbell, Inc., Bostwick Ave., plans to build a 4-story manufacturing plant on State St. Estimated cost, $175,000.

MERIDEN—The Miller Bros. Cutlery Co., 464 Pratt St., has awarded the contract for the construction of a 4-story, 50x90-ft. manufacturing plant addition on Pratt St., to the J. H. Grozier Co., 721 Main St., Hartford. Estimated cost, $50,000. Noted March 17.

Illinois

CHICAGO—B. Kuppenheimer & Co., 423 South Franklin St., is building a 3-story factory building at 20th St. and South Karlov Ave. Estimated cost, $500,000.

CHICAGO—The Troco Nut Butter Co., 30 North Michigan Ave., has awarded the contract for the construction of a 4-story, 100x112-ft. factory at 37th and Iron Sts., to E. W. Sproul Co., 2001 West 39th St. Estimated cost, $250,000. Noted March 31.

WOODRIVER—The Standard Oil Co., Syndicate Trust Bldg., St. Louis, Mo., plans to construct a lubricating oil plant in addition to the other large projects, at its plant, here.

Indiana

TERRE HAUTE—The Columbian Enameling & Stamping Co. has awarded the contract for the construction of a 1-story, 155x240-ft. factory, to Roehm Bros., Denning Bldg. Estimated cost, $100,000.

Kansas

SCOTT CITY—The city will receive bids about May 1 for the construction of a sanitary sewerage system and a sewage disposal plant. Estimated cost, $75,000. Ruckel Eng. Co., Hutchinson, engr.

Kentucky

LOUISVILLE — The Visible Measure Gasoline Dispenser Co., 700-800 West Breckinridge St., plans to build a 2-story factory addition at 8th and Breckinridge Sts. Estimated cost, $25,000. G. Cunningham, genl. mgr.

Maryland

ASBESTOS—Arthur E. Van Bibber, 6337 Drexel Rd., Philadelphia, Pa., has purchased the plant of the Baltimore Roofing & Asbestos Mfg. Co., here, and plans to use same for the manufacture of linoleum and roofing.

BALTIMORE—The Amer. Sugar Refining Co., 117 Wall St., New York City, has awarded the contract for the construction of a sugar refinery including several 5- to 8-story buildings at Locust Point harbor front, to Stone & Webster, 117 Wall St., New York City. Estimated cost, $8,000,000.

BALTIMORE—S. W. Wiley & Co., Inc., analytical and consulting chemists, 7 South Gay St., is having plans prepared for the construction of a 3-story, 50x122-ft. chemical laboratory at 900-904 North Calvert St. Estimated cost, $150,000. W. G. Beecher, Frederick Rd., Catonsville, archt.

CURTISS BAY (Baltimore P. O.)—The Prudential Oil Co., Inc., 310 Keyser Bldg., Baltimore, will soon receive bids for the construction of a 1-story, 72x129-ft. oil refinery on 3rd and 4th Aves. Estimated cost, $25,000.

DUKES (Adelina P. O.)—The West Virginia Pulp & Paper Co., 200 5th Ave., New York City, will build 50x90-ft. and 100x120-ft. additions to its plant. Work will be done by day labor. Noted March 23.

Massachusetts

BROCKTON—George L. Falk, archt., 63 Main St., will soon award the contract for the construction of a 3-story, 55x160-ft. dry kiln building on Cherry St., for the Miller Tree Co. Estimated cost, $50,000.

CAMBRIDGE—The Prest-O-Lite Co., Inc., 30 East 42nd St., New York City, is having plans prepared for the construction of a few 1-story, 25x100-ft. acetylene plants. Estimated cost, $80,000.

CHICOPEE—The Fiske Rubber Co. has awarded the contract for the construction of 2-, 3- and 5-story factory additions, to Fred T. Ley, 19 West 44th St., New York City. Estimated cost, $150,000.

WEST SPRINGFIELD (Springfield P. O.)—The Gilbert & Barker Mfg. Co., Cold Springs Ave., has awarded the contract for the construction of 12 buildings, including a 2-story, 80x400-ft. brass foundry, 1-story, 40x80-ft. zinc building, 2-story, 164x200-ft. sheet metal building and a 1-story, 14x63-ft. testing building, to Tucker & Lewis, Inc., 101 Park Ave., New York City. Estimated cost, $1,000,000. Noted March 10.

Michigan

DETROIT — Albert Kahn, archt., Marquette Bldg., will receive bids until April 15 for the construction of a 1-story, 175x282-ft. factory on Mt. Elliott and Strong Aves., for the Detroit Pressed Steel Co., 1800 Mt. Elliott Ave.

DETROIT—The Wolverine Auto Painting & Trimming Co., c/o Atwood & Trysell, archts., 603 Temple Bldg., is having plans prepared for the construction of a 2-story, 90x100-ft. enameling plant at Herbert and Martin Sts. Enameling and painting equipment will be installed in same. Estimated cost, $25,000.

GOODELLS—The Brass & Aluminum Fdry. Co. is in the market for a brass furnace.

MILAN—The Amer. Furnace & Fdry. Co. has awarded the contract for the construction of a 1-story, 75x200-ft. foundry along the Michigan Central R.R., to Thomas Gotts. Estimated cost, $50,000.

Minnesota

RENVILLE — The Bd. Educ. plans to build a 2-story, 80x240-ft. junior and senior high school. A chemical laboratory will be installed in same. Estimated cost, $300,000. Croft & Boerner, Palace Bldg., Minneapolis, archts. and engrs.

Missouri

MAPLEWOOD (St. Louis P. O.)—The Bowen Motor Car Co., Title Guaranty Bldg., has purchased a 21-acre site here and plans to build a plant for the manufacture of gasoline driven standard gage railway cars, on same.

ST. LOUIS—The Century Electric Co., 18th and Pine Sts., is building a factory. Estimated cost, $500,000. Noted Jan. 21

Montana

FORSYTHE—The Bd. Educ. plans to build a high school. A chemical laboratory will be installed in same. Findlay & Ferner, archts.

New Jersey

NEWARK—The General Lead Batteries, 123 West 56th St., New York City, will build a 5-story factory at Lester Ave. and Chapel St. Estimated cost, $150,000. Work will be done by day labor. Noted Feb. 11

NEWARK—The Hanovia Chemical & Mfg. Co., Chestnut St. and the New Jersey R.R., has awarded the contract for the construction of a 3-story, 40x75-ft. chemical factory, to the Becher Constr. Co., 361 Grove St.

NEWARK—The Simms Magneto Co., North Arlington Ave., East Orange, has awarded the contract for the construction of a 2-story, 177x231-ft. addition to its present building on North Arlington Ave., to the Amer. Concrete Steel Co., 27 Clinton St. Estimated cost, $385,000.

NEW BRUNSWICK—The Trenton Porcelain Co., 803 East State St., has awarded the contract for the construction of a 1-story, 30x150-ft. porcelain plant, to F. R. Parker, 327 Calhoun St., Trenton. Estimated cost, $20,000. Noted Feb. 11.

TRENTON—The Cook Linoleum Co., East State St., has awarded the contract for the construction of a 1-story, 79x169-ft. plant addition, to J. H. Morris, Broad St. Bank, at $50,000.

TRENTON—The Nearpara Rubber Co., 79 Prince St., has awarded the contract for the construction of a 1-story, 100x125-ft. rubber plant, etc., to the Bethlehem Constr. Co., Bethlehem Trust Bldg., Bethlehem, Pa. Estimated cost, $150,000.

New York

ALBANY—The Albany Perforated Wrapping Paper Co., 1271 B'way., plans to build a 1-story addition to its plant. Estimated cost, $210,000.

BROOKLYN—The Keystone Varnish Co., 71 Otsego St., is having plans prepared for the construction of a 4-story, 50x100-ft. factory addition at 73 Otsego St. Estimated cost, $85,000. John E. Nitchie, 63 Park Row, New York City, archt. and engr.

BUFFALO—The Dept. of Pub. Wks. will receive bids until April 17 for the delivery of 80,000 lb. of liquid chlorine between May 1, 1920, and May 1, 1921.

BUFFALO—The Globe Belting Co. plans to construct a manufacturing plant at 1396 Clinton St. Estimated cost, $15,000.

BUFFALO—The Interlocking Reinforced Concrete Corp., East Ferry St. and the Erie R.R., has awarded the contract for the construction of a 1-story, 125x600-ft. factory, to J. Bellony, Builders' Exch. Bldg. Estimated cost, $25,000.

DUNKIRK—The Atlas Crucible Steel Co. plans to build a 70x200-ft. electric melting building, annealing buildings, etc., at its plant here. A 6-ton Heroult furnace, a 26-in. rolling mill and a 16-in. rolling mill, as well as other heating and annealing furnaces, etc., will be installed in same. This plant when completed will include three 30-pot furnaces, two 6-ton and one 3-ton Heroult electric furnaces, one 20-ton basic hearth furnace, hammers, rolling mills, wire mill, laboratory, inspection and shipping departments. Estimated cost, $1,800,000.

EAST SYRACUSE (Syracuse P. O.)—The East Syracuse Live Stock Rendering & Fertilizing Co., Inc., has purchased a site here and plans to construct a large packing plant on same. H. T. Riley, pres.

GOWANDA—The Eastern Tanners' Glue Co. plans to build an addition to its factory, here.

HAMBURG—The village is having plans prepared for the construction of a sewerage system and a sewage disposal plant. A $250,000 bond issue has been passed for the project.

LONG ISLAND CITY—Fahnestock Electric Co., Skillman Ave., has awarded the contract for the construction of a 2-story, 50x100-ft. factory at East Ave. and 8th St., to C. C. Woodruff, 213 16th Ave. Estimated cost, $52,000.

PYRITES—The De Grasse Paper Co. had plans prepared for the construction of a 1-story, 60x208-ft. machine room at its plant, here. Estimated cost $154,000.

THERESA—The Orleans Four Corners Dairymen's League Cooperative Association, Inc., is in the market for milk handling machinery, refrigeration system and milk-testing laboratory equipment.

TONAWANDA—T. J. Ballary, engr., will receive bids until May 5 for the construction of a filtration plant for the city. Estimated cost, $200,000.

Nevada

MINA—The Olympic Mines Co. plans to build a new mill on the site of the old one, which was destroyed by fire. The mill will have a capacity of 75 tons and will treat the ores from both the Olympic and the Loo mines. Estimated cost, $100,000.

North Carolina

HICKORY—The mayor has awarded the contract for the construction of a sewage disposal plant, to Tucker & Laxton, Inc., Charlotte, at $21,000.

North Dakota

HANKINSON—The Bd. Educ. will install a chemical laboratory in the proposed high school here.

Ohio

CINCINNATI—The Amer. Can Co., 120 B'way., New York City, plans to construct several 1- and 3-story factory buildings on Fergus St. Estimated cost, $1,000,000.

CINCINNATI—The Standard Silicate Co. has awarded the contract for the construction of a 2-story, 98x160-ft. and a 1-story, 49x80-ft. factory building on Paddock Rd., to the Fisher De Vors Co., 36 Blymyer Bldg. Estimated cost, $750,000. Noted March 17.

CLEVELAND—The Bd. Educ., East 6th St. and Rockwell Ave., plans to build a 3-story high school at the University Circle. Chemical equipment will be installed in same. Estimated cost, $5,000,000. F. G. Hogan, dir. U. R. McCormack, East 6th St. and Rockwell Ave., archt.

CLEVELAND—The Carbonized Steel Products Co., 331 East 140th St., has awarded the contract for the construction of a 1-story, 40x60-ft. factory, to the Sam Emerson Co., 1900 Euclid Ave. Estimated cost, $6,000.

CLEVELAND—The Euclid Fdry. Co., c/o Hulett & Stanton, archts., 226 West Superior Ave., has awarded the contract for the construction of a 1-story, 125x140-ft. foundry on St. Clair Ave. and the New York Central R.R., to the Complete Constr. Co., 226 West Superior Ave. Estimated cost, $100,000.

EAST CLEVELAND (Cleveland P. O.)—The Natl. Lamp Co. of the General Electric Wks., Nela Park, has awarded the contract for the construction of a 1-story, 100x220-ft. laboratory at Nela Park, to the Austin Co., 16112 Euclid Ave., Cleveland. Estimated cost, $100,000.

ELYRIA—H. A. Beck, Dir. of Pub. Serv., City Hall, will receive bids until April 26 for the construction of a filtration plant, substructures and appurtenant works, including coagulating basin, filtered water reservoir, rapid sand filter tanks, etc.

TRUMBULL—The Bd. Educ. R.F.D. 3, Youngstown, is having plans prepared for the construction of a 2-story, 91x150-ft. school on Churchill Rd. Chemical laboratory equipment will be installed in same. Estimated cost, $150,000. C. Cliffe, clk. Miller & Son, 408 Dollar Bank Bldg., Youngstown, archts.

WARREN — The General Fire Extinguisher Co. has awarded the contract for the construction of a 2-story, 100x200-ft. foundry, to the Foundation Co., 233 B'way., New York City. Complete foundry equipment will be installed in same. Estimated cost, $350,000.

Pennsylvania

HARRISBURG—The Harrisburg Water Dept. plans to install 6 additional filters, etc., at the filtration plant. S. F. Hassler, comr.

WHEATLAND—The Slick Knox Steel Co., c/o W. L. Ulmer, dir., Hippodrome Bldg., Cleveland, O., plans to construct a 1-story steel mill. Estimated cost, $300,000.

Texas

BRYAN—The city has awarded the contract for the construction of a sewerage system and a sewage disposal plant in the eastern section of the city, to F. L. Young, 306 Pershing Ave., San Antonio. Estimated cost, $35,844.

Wisconsin

CARROLLVILLE—The United States Glue Co. has awarded the contract for the construction of a 3-story, 377x500-ft. food manufacturing plant, to Paul Riesen's Sons, 1018 Humboldt Ave., Milwaukee. Estimated cost, $2,000,000. Noted March 10.

KOHLER—The Kohler Co. will build a 1-story, 100x290-ft. foundry. Work will be done by day labor.

MILWAUKEE—The Trapp Bros. Dairy Co., 86 Burleigh St., has awarded the contract for the construction of a 2-story, 70x110-ft. dairy on Burleigh St., to the R. Reisinger Co., 425 East Water St. Estimated cost, $75,000.

WEST ALLIS—The Allis-Chalmers Mfg. Co. has awarded the contract for the construction of a 1-story, 130x500-ft. foundry, to Klug & Smith, 40 Mack Block, Milwaukee. Estimated cost, $200,000.

West Virginia

CLARKSBURG—The city has awarded the contract for building an intake chamber and installing coagulating basins and equipment for pumping station, to the Richards Constr. Co., at $37,108.

Ontario

HAMILTON—T. B. McQuestin, Chn. of the Civic Gas Committee, has recommended that the city build a gas manufacturing plant. Estimated cost, $3,000,000. E. R. Gray, City Hall, engr.

KITCHENER — The Young Business Men's Association plans to construct a large hockey and skating arena. Chemical equipment required in connection with ice making will be installed in same. Estimated cost, $250,000.

Quebec

MONTREAL—The Barrett Mfg. Co., 2004 St. Hubert St., is having plans prepared for the construction of an addition to its tar products plant. Estimated cost, $32,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive at St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHAMBER OF COMMERCE OF THE U. S. announces that its eighth annual meeting will be held at Atlantic City, April 27 to 29, the subject of which will be "Increased Production."

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theater: "Water Supply and Drainage in War Cantonments," Wednesday, April 21, at 4 p.m., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers Process), Thursday, April 29, at 4 p.m., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 p.m., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 p.m., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E., will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MINE INSPECTORS' INSTITUTE OF AMERICA will hold a meeting at Cleveland, Ohio, July 13, 14 and 15.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5 which will be held in Glace Bay.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE NATIONAL SAFETY COUNCIL, Engineering Section, will hold its spring conference in the Engineering Societies Building, New York City, on April 27.

THE NEW JERSEY CHEMICAL SOCIETY plans the following: Saturday, April 24, 2:30 p.m., visit to the plant of the Raritan Copper Co., Perth Amboy, N. J.; Monday evening, May 10, regular meeting; Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J., regular meeting and ladies' day.

THE NITROGLYCERINE MANUFACTURERS' ASSOCIATION will hold a meeting in Chicago, April 19 and 20.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Industrial Notes

HARRY J. WOLF, formerly associate editor of *Engineering and Mining Journal*, announces that he has resumed the general practice of mining engineering, with office at 42 Broadway, New York City.

THE ROESSLER & HASSLACHER CHEMICAL Co. announces that the main office has been removed to 709-717 Sixth Ave., corner 41st St., New York City.

THE OXWELD ACETYLENE Co., of Newark, N. J., and Chicago, has recently extended its manufacture of oxy-acetylene apparatus and equipments to include "Eveready" welding and cutting outfits. "Eveready" is a new name in the oxy-acetylene field, but the apparatus is not new, excepting for certain refinements of design, having been used extensively in the metal-working trades for several years under the name of "Prest-O-Lite" apparatus. The new name was adopted by the Oxweld company to suggest the ready convenience, adaptability and general-purpose uses of the equipment. The apparatus is designed for use exclusively with compressed acetylene in cylinders, thus providing the welder and cutter a compact and complete portable outfit.

CHARLES C. PHELPS has become associated with the Uehling Instrument Co., 71 Broadway, New York, combustion engineer and manufacturer of CO_2 recording equipment and other fuel economy apparatus. He is devoting most of his attention to research work in connection with the efficient combustion of fuel oil in boiler furnaces. Mr. Phelps graduated from Stevens Institute of Technology with the degree of mechanical engineer and has since spent several years studying power-plant problems. For five years of this period he was connected with the Ingersoll-Rand Co., manufacturer of power-plant equipment and pneumatic machinery.

JOHN A. KIENLE, formerly sales manager of the Electro Bleaching Gas Co., has been appointed general manager of sales of the Mathieson Alkali Works, Inc. This change was brought about by the severing of relations between the Mathieson Alkali Works, Inc., and its former sales agent, Arnold, Hoffman & Co., Inc. It is the intention of the Mathieson Alkali Works, Inc., to sell all of its products (caustic soda, soda ash, virginia soda, bicarbonate of soda, bleaching powder, liquid chlorine, chlorine solvents, etc.) direct to the consumer instead of through sales agents. Mr. Kienle has been placed in charge of the development of a complete sales organization. E. E. Routh, formerly manager of bicarbonate sales, has been appointed assistant to Mr. Kienle.

Standard Samples To Continue

IT IS with great regret that we learned that the House of Representatives and the Senate both declined to grant to the Bureau of Standards continuance of the fund for the preparation and distribution of standard samples. This small sum, amounting to $5,000 a year, was, as we have previously pointed out, really self-supporting, as the cash income from the work was more than $6,000 during the last fiscal year. In fact, credits for work done for state and Federal departments brought the total book value of the income up to over $10,000.

Despite this interruption of the appropriation, it has been decided by the Bureau of Standards to continue, at least in part, the standard sample work, and we congratulate that institution on this decision, even though we realize it had to be made with the understanding that certain other work would suffer correspondingly because of this burden being absorbed by the regular funds of the Bureau. In return for this self-sacrificing decision, the industries and our educational institutions owe a debt to the Bureau of Standards which should be recognized and met. Our metallurgical industries should in every way possible co-operate with the Bureau in securing the necessary irons, steels, brasses and other materials at a nominal expense to it, thus reducing the cost of preparation of the samples to a very minimum. The educational institutions should also co-operate by a very sparing use of the materials, refraining altogether from their use in student work except for purposes of research or in work of an advanced nature.

The cost and difficulty of preparing standard metal samples are little appreciated by those who have not given thought to this matter. It is an easy thing to ruin a sample of many hundred pounds after weeks of careful work had been put on it if for any reason a portion of it comes to have a slightly different composition than any other part of the mass. Very few institutions have either the facilities or the skill required for the painstaking work of this preparation. It is really a serious matter, therefore, when material prepared at great expense of time and skill is used unnecessarily by instructors as student samples. The Bureau quite properly declines to supply materials for such use when it has knowledge of the circumstances. It is suspected, however, that much use is being made of the materials without the knowledge of the Bureau, we would urge any who have unwittingly done this to discontinue such practice.

We trust that by another year Congress will come to appreciate the great importance and value of this activity and will appropriate for its continued growth in a measure commensurate with its work.

Iron Castings in Iron Molds

EVERY so often the question pops up, "Why are not permanent molds more widely used for iron castings?" The questioner may have in mind the great success of die casting as applied to white metal alloys or more recently to the more difficult aluminum bronzes; or he may have a recollection of having heard that such a procedure has been or could be applied to the iron foundry.

Perhaps the usual answer if the question were put to the "old-timer" would be that chill castings would have a heavy skin of white iron and the machine shop could do nothing with them. The answer would be entirely correct, and could be substantiated at any time by pouring a little of the iron regularly coming from the cupola and destined for green sand into a pig mold. The depth of the white-iron shell might even be intensified by filling a heavy deep iron cup. Examination of this sample when fractured would immediately show whether there was any possibility of a die-cast piece being machinable, a test used by OUTERBRIDGE for over thirty years. He it was who discovered and put to thorough commercial application a long time ago the fact that if the metal possessed the correct composition, either by original melting or by ladle additions of ferromanganese and ferrosilicon, such a chill cup would not produce even the thinnest skin of white iron, and a properly designed mold would give a commercial casting, soft and strong, very fine grained, almost steel-like in appearance after machining, yet having practically no combined carbon at all. He first set chill blocks in sand molded gear wheels, so that the rate of solidification could be so controlled that an accumulation of deep-seated cavities would not appear at the arm-junctions. From that point, progress naturally suggested a like practice on lathe beds, where dense sound iron is requisite.

If correct iron could cool against a series of blocks set in supporting sand without developing hard spots in the casting, there seemed no reason why the entire mold should not be made of iron, even to any necessary cores.

OUTERBRIDGE did it, and has made over a million castings in iron molds, machinable castings of exceedingly fine grain, free of dirt, sponginess and other defects, and having a marked increase in strength over the sand-cast metal. In this work the cores were withdrawn quickly to prevent seizure, but the casting cooled black in the mold.

This work at the Sellers foundry was kept a close secret for many years, with only bits of information leaking out from time to time. Therefore later work was along independent lines and without advantage of the accumulated experience at this particular foundry.

As an instance, CUSTER designed die-casting machines for soil-pipe fittings, which operated commercially for some time. This was before the days when the widespread introduction of molding machines had so largely reduced the labor expense on sand molds, and correspondingly dulled the spur to reduce molders' labor to the extreme minimum. Instead of using his molds once a day, CUSTER held the hot iron in the mold but a minimum of time necessary to maintain its form, when the cores were withdrawn, the mold opened, and the hot casting cooled in air. In this manner a single mold, operated by hydraulic power, could produce a hundred castings or more every shift. Such casting practice apparently allows a much wider range of chemical composition in the fluid iron than the Sellers method, since any cementite forming at the quick-solidifying surfaces is annealed into ferrite and temper carbon during subsequent slow cooling.

As is the case for die castings for white metal, such permanent molds are quite expensive to design and construct, much care being necessary to provide properly for gates, vents and traps. Unfortunately the molds, and especially the cores, are short lived. They ordinarily fail by surface disintegration, showing as a swelling, cracking and spongy layer of variable depth, which causes difficulty in shaking out the casting and ruins its surface appearance. This deterioration in the mold is caused by the well-known property which cast iron has of growing when heated repeatedly to redness. Yet so little known and so little under control is this fundamental property of the permanent mold that one metallurgist recommends the use of low-silicon white iron, which has less than the ordinary amount of growth, for molds which should never be brought in any part to a visible heat, while another experienced in bronze die-castings, whose working temperatures are comparable to that of iron, recommends the use of a close-grained iron with low combined carbon—a combination which is hard to get except by chilling high-silicon iron.

In the light of current literature and common information, the subject of iron castings in permanent molds offers an attractive field for experimentation and profitable application, either along the lines of casting in dies, with or without extraneous pressure, and with sand or metal cores, or of casting cylindrical pieces in centrifugal machines without molds, gates or risers of any kind.

How little it is applied today may be inferred from the fact that a large foundry producing 1,000 tons of automobile engine-parts every day makes but one part in permanent molds, and that in a centrifugal machine. At that its practice is to remove the castings, and cool in mica or ashes, and even this fails at times to produce machinable rings.

Even with all this in mind, one feels justified in saying that certain castings requiring a very fine grain, and uniform texture; free from blow holes, shrink holes and pipe; high strength and practically no combined carbon can be turned out in large quantity with a minimum molding expense in permanent molds in a manner unapproachable by any other known method. When this fact is widely known, the method itself will be intensively studied and widely applied by the largely increasing numbers of inquisitive metallurgists now questioning the sacred traditions of the iron foundry. Only men of this type would attempt what seems so bizarre, and almost foolish.

Research and Imitation Research

IN THE years past the fundamental schooling for industrial achievements was apprenticeship. The "old-timers" instructed the novices in the intricacies of the trade, which were considered as secrets to be revealed only to the apprentice. The guilds of the different industrial arts were comparable in a way with the unions of to-day, with the distinction that the former were solely protectors of the trade, while the latter are concerned chiefly with the problem of fixing higher monetary compensation for their members. The question of sound industrial progress through systematic technical improvement has received but scant attention by such organizations of workers.

It is only in recent years that systematic research work has been undertaken in order to further the progress of practically all branches of technical art; but, like any other innovation, it is liable to trespass the limits of actual usefulness, drift into mere duplication of effort or produce results hastily accepted as improvements at the cost of great expenditures in time and money.

The technical school of to-day feels that it can no longer confine its attention to an academic presentation of the theoretical intricacies of a particular subject; it must combine theory with as many practical applications as possible, with research work as the finishing touch for the technical graduate. Competition among the various schools has resulted in the establishment of research laboratories and courses in research at substantially all of the American technical institutions, and even as separate departments of the graduate school in the universities. Research work is very expensive, and the question arises as to whether the funds thus used might not have been applied in many cases to better advantage—in improving the salaries of the teaching staff, for example.

In the recently published report of the Carnegie Foundation for the Advancement of Teaching, the president, Dr. HENRY SMITH PRITCHETT, says:

"Much of that which has gone on in American universities under the name of research is in truth only an imitation of research and upon it great sums have been expended. College salaries also have been diluted enormously by the tendency of most college faculties and governing bodies to bid for students by extending the curriculum over the whole field of knowledge, a process which means great increase in the number of teachers and the consequent leveling down of salaries."

The need for productive research in pure and applied science is urgent, but we must not lose sight of the fact that not all students are endowed with the temperamental prerequisites of the research worker. On the other hand, industry must have technically trained men who are able to interpret and apply the results of research in the plant. Dr. PRITCHETT suggests that the universities take stock of themselves and "render a sincere and critical statement of the results obtained in education by the expenditures of the last twenty-five years." Is it not possible that such introspection would reveal the fact that we have placed too much stress upon the mere formalities of the "research course," without careful consideration of the needs of science and industry, the potentialities of the graduate student entering such work, and the capabilities of the faculty nominally in direction?

Alive to The Situation!

AMERICANS like to tell themselves and advertise to strangers that we are the most progressive, the most far-seeing and the most everything else you want to mention. That is to say, a certain egotistical minority do the advertising, and the rest of us believe we can see an ell, at least.

Yet nine out of ten of us cannot see an obvious event until it knocks us down and runs over us, despite the unheeded warnings of the active publicist or propagandist. We pay no attention to him because we don't trust him; because we feel there must be a sinister hidden influence somewhere; because we think he is trying to use us for the profit of himself or his applications; or because he is labeled as a plain crank.

So it is that nearly everyone buys on a rising market, few build when prices are low, and improvements in technology are left for the other fellow to develop. Nor will we give heed to plain economic tendencies until it is almost too late.

Picture the anguished consternation of the well-to-do professional man who has never been seriously inconvenienced by labor troubles finding that there are no accustomed trains to carry him the intervening miles from his home to his work. Labor troubles before have been impersonal things, perhaps inconveniencing the other fellow a bit and maybe slightly reflected in inflated prices. "But here! No trains! Is it possible that a few railroad switchmen have the whole country by the throat? Can a few bolsheviks hold up the nation and rob it with impunity? Somebody ought to be lined up against the wall and shot! Outrageous!"

All because the 8.17 is not running!

Steel Prices And Other Prices

WHEN during the war the Government began fixing prices it was held that a new system was inaugurated, that previously prices had been fixed in but one way, by "the law of supply and demand," except when the wicked trusts got in their work. Government price control ended, generally speaking, at the close of 1918, a few weeks after the Armistice, and an effort in the following March to regulate prices under Government auspices failed for a variety of reasons. Are prices now fixed by the law of supply and demand? One can hardly maintain that they are.

To point out proofs that prices are not now fixed by the law of supply and demand, however, is to develop some arguments that could have been used before the war to show that even then prices were not set by the "law" of supply and demand, which would make it appear that it isn't a law after all, but something cognate rather to a motto, a motto being something that one follows, if at all, only at his convenience.

For supply and demand to set prices would really mean in substance that the material to be sold is auctioned off day after day to the highest bidders, and that hardly occurs. It seems curious that we should have been talking so much about the law of supply and demand when so little evidence could be found of its actually being the controlling influence. One reason can be vouchsafed, that it represents the continuance of an idea after the circumstances that created it have disappeared in very considerable part. Imagine all products made by individuals, each man being his own manufacturing concern, with practically no capital investment in factory or materials, and a good many of the men jack of all trades so that they can shift from one class of goods to another. Then if the demand for gloves decreases the price falls until some of the men turn to making shoes, for which satisfactory prices are obtainable. The decline in gloves is arrested before anybody starves through inability to make enough gloves per day, at the low price prevailing, to buy him his bread and butter.

With the factory system this regulation cannot occur, and the factory system has been growing up for decades. If it does not hamper the operation of the old law of supply and demand, which would work in conditions like those just imagined, it at any rate would make a very unfortunate situation at times. This, indeed, it has done, and the fact that there have not been glaring cases in recent years does not indicate that experiences of the more distant past cannot be repeated, and on a larger scale. Those who lived through the industrial depression of 1893 to 1898 can readily recall the term so common then, "bankrupt competition." Numerous manufacturing concerns failed. Some of them had been promoted by country towns by a cash bonus, free land and exemption from taxation for a period of years. The promoter came along, was given possession of the factory merely in return for his promise that he would operate it and, presto, there was a manufacturer whose cost sheet had no blanks to fill in for amortization, obsolescence, depreciation, taxes or interest on investment. Respectable and responsible manufacturers, producing the same class of goods, paying taxes, conducting a legitimate business and entitled to thrive, were exposed to this "bankrupt competition."

Prior to the war competition was a factor in influencing commodity prices, and there was also the influence of manufacturers and sellers generally feeling that if they embraced an opportunity to make inordinate profits, when presented, retribution would likely come some time.

Selling prices now are made largely by what manufacturers think it right and proper to charge, and as there is a wide diversity of opinion among sellers, there is also a wide diversity of prices. In the steel industry, for instance, there is the United States Steel Corporation, which makes about 44 per cent of all the country's steel products, sedulously adhering to a certain schedule of prices, which chances to be the Industrial Board schedule that became effective March 21, 1919, and the independents all asking and securing higher prices, in some cases by half a cent a pound, in other cases by three or four cents a pound. If this were the result of the operation of any law of supply and demand, the Steel Corporation's products would be proved to be sonimous (word coined by CHARLEY SCHWAB) beyond ordinary powers of conception. Go into a hardware store, make a collection of tools all made of much the same material, brass, steel, etc., and by quite the same classes of workmen, and inquire how present prices compare with those of 1915. Some of those tools will be found to have advanced two or three times as much as others. That is the difference in the psychology of the makers, not any difference in the cost of the raw materials and labor.

Readers' Views and Comments

Mineral Resources and Chemical Industries of the Southern States

To the Editor of Chemical & Metallurgical Engineering

SIR:—The writer has read with much interest the article by Andrew M. Fairlie on "Some Developed Mineral Resources and Chemical Industries of the Southern States," in your issue of Feb. 18. Considerable attention is there devoted to the Southern phosphate fields which are now developed. It is the purpose of this communication to call attention to an as yet undeveloped phosphate deposit in the Southern States which is of peculiar interest.

I refer to the dahllite and collophanite found along the junction of the shaly limestone and Watanga shale in Johnson County, east Tennessee. This deposit was just noticed in 1915, when the Tennessee State Geological Survey made as detailed a report as the undeveloped condition of the field would permit. Such work as has been carried out up to the present time shows the presence of considerable amounts of phosphatic material containing 60 to 75 per cent tricalcium phosphate, as well as very large amounts of rock which is of a lower grade.

The economic importance of this bed is not so much as a source of phosphorus *per se*, but more especially its proximity to coal, coke, sulphuric acid and silica. Conditions are peculiarly favorable for the putting of this material into marketable form either as fertilizer or as elemental phosphorus. STUART W. MAHER.

The History of Mustard Gas

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reference to the recent article on the History of Mustard Gas by Clarence J. West in your issue of March 24, 1920, Mr. West, as well as the authors of the controversy as to the discovery and commercial development of the reaction between ethylene and sulphur chloride, seems to have lost view of two extremely important points. One is that whatever the merits of the inventors and of the authors of the very large program of mustard gas to be manufactured (for home consumption, for it never reached the enemy), the only one of the Allies that manufactured and fired mustard gas was the French, and the other point is that whatever the merits of the Levinstein process the sulphur dichloride process furnished practically the whole of the mustard gas that was ever used against the Germans.

To be sure, this should not detract in any way from the merits of the Levinstein process, which doubtless would have become universal had the war lasted much longer, but, since the article purports to be a historical article, it should certainly mention that as a historical fact the sulphur dichloride process was the only one which was actually producing on a large scale in time to allow its product to be used against the enemy. In a series of confidential reports which I made to the Chemical Warfare Service I followed from February, 1918, until the armistice the progress which was being made by the plant of the Société Chimique des Usines du Rhone.

This plant started early in March with a production of two to three tons a day and was in July producing close to twenty tons a day. It was being duplicated at the time of the armistice, so that probably by December, 1918, the production of mustard gas by the dichloride process would have reached about forty tons. Early in June the first consignment of shells filled with mustard gas reached the French front and I believe about June 18 the first mustard gas shoot conducted by any of the Allies was carried out by the French.

I had occasion to mention this fact before at a meeting of the Société de Chimie Industrielle, an account of which was published in your journal[1], but evidently it seems to have escaped Mr. West's attention as well as, which is more inexplicable, the numerous reports to which Mr. West had access during his long and successful connection with the Chemical Warfare Service.

Mr. West's remarks regarding the sulphur dichloride process create the impression that it was never successfully worked even in the laboratory, when, as a matter of fact, it was practically the *only* process that was working in time to be of military use, the mustard gas made by other methods in France amounting then to only a few tons.

I hold no brief for the dichloride process. Besides the complicated and costly apparatus, it required considerable quantities of carbon tetrachloride. a solvent which was very scarce during the war, but when the matter is looked at historically the fact remains that it was the only one which was developed and running on an industrial scale when all others had just graduated from the laboratory or barely entered the semi-industrial stage. J. E. ZANETTI.

Need of Co-operative Educational Work in the Chemical Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—The reference to the American Cranberry Exchange, on page 511 of your issue of March 17, recalls a story which may or may not be familiar to the cranberry men, but which seems at any rate to have some advertising value.

A native of Cape Cod, in the course of conversations with an old French chef, happened to mention the cranberry. "Ah, ze crranberry," said the chef, "I know ze crranberry; you take heem and you stew heem, an' he make ze better apple sauce zan ze prune do."

If our cranberry-growing friends wish to make use of the story in advertising their product, I will cheerfully waive all proprietary rights.

CHARLES RIVER SKYLINE OF BOSTON

Boston Meeting of the American Electrochemical Society

Symposium on Colloids—Joint Meeting With the American Institute of Electrical Engineers—Discussion on Ferro-Alloys and Power for Electrochemical Industries—The Electric Brass Furnace

THE thirty-seventh general meeting of the American Electrochemical Society was held in Boston, April 8 to 11. In spite of unsettled business conditions, difficulties in traveling and lack of ample hotel accommodations, the meeting was one of the best attended for many years. There were over 300 members and guests registered. Animated and stimulated discussions of the pre-war type prevailed; these were characterized by the open-minded attitude of former days, which of necessity had dwindled during the war. Among the social features, the big Little smoker will linger long in the memories of all.

Meeting of the Board of Directors

At the meeting of the board of directors the treasurer's annual report was submitted. The liquid assets of the Society aggregate $17,000. The membership committee, C. G. Schluederberg, chairman, reported a present total of 2,307 members, as compared with 1,903 members on Jan. 1, 1919. Among the new business transacted, it was moved to circularize the membership and ascertain the opinion of the individual on the general adoption of the metric system in this country. President Bancroft appointed Messrs. Landis, Richards, Lash, Miller, Chaney and Tucker a committee of five to consider carefully the various proposals for the next meeting place of the Society and to report to the board not later than May.

Officers Elected at Annual Business Meeting

The annual business meeting was held in Huntington Hall. Upon the report of the tellers, the following officers were declared elected: President, W. S. Landis: vice-presidents, J. A. Mathews, L. E. Saunders and A. T. Hinckley; managers, Colin G. Fink, Acheson Smith and H. B. Coho; treasurer, Pedro G. Salom; secretary, Joseph W. Richards.

Technical Session—Thursday Morning

Prof. Henry P. Talbot of the Massachusetts Institute of Technology welcomed the members of the Society and dwelt briefly upon the ever-increasing importance of electrochemistry. The war has demonstrated most emphatically that "the ultimate defense of our country lies in the hands of electrochemistry."

The presidential address of the retiring president, Wilder D. Bancroft, dealt with the present aspects of contact catalysis theory. The action of infra-red radiation was discussed at length and the conclusion drawn was that until some proof is brought that a contact catalytic agent can act at a distance, we are justified in postulating that the reaction takes place in or at the surface. A corollary from this is that any substance which cuts down the rate at which the reacting substances reach the catalytic surface, or which prevents them from reaching it, will decrease the reaction velocity, and may destroy the catalytic action entirely.

The piling up of the reaction products will cut down the reaction velocity, if they prevent the reacting substances from coming in contact with the catalytic agent. This has been observed in the contact sulphuric acid process, where sulphur trioxide inhibits the reaction by sealing off the reacting SO_2 and O_2 from the platinum sponge.

Since reaction velocity is probably directly propor-

tional to the difference of chemical potential and inversely proportional to the chemical resistance, we can increase the reaction velocity either by increasing the difference of chemical potential or by decreasing the chemical resistance. When the reacting substances are adsorbed at the surface of a catalytic agent, there is a marked increase in the concentration and it has been suggested that this is the cause of catalytic action. As a matter of fact, the effect of concentration seems to be relatively unimportant in most of the cases studied hitherto. It is stated that oxyhydrogen gas has been found to be quite stable under pressures of 2,000 atm., which shows that the catalytic action of platinum on mixtures of hydrogen and oxygen must be due to something more than a change in concentration.

If we have selective adsorption of the reaction products, this will cause a lowering of the chemical potential of the resultants and will therefore increase the reaction velocity. It may even determine the direction of the reaction. Alcohol breaks down into acetaldehyde and hydrogen in presence of pulverulent nickel and into ethylene and water in presence of pulverulent alumina. Since nickel adsorbs hydrogen strongly and alumina adsorbs water, it seems natural to assume that the selective adsorption is the determining factor. However, this conclusion does not work well with the fact that the latter reaction is very much facilitated by the addition of steam.

If changes in the chemical potential are not the important factors in contact catalysis, the catalytic agent must change the chemical resistance in some way. There are two possible means for this, either more effective collisions between the reacting molecules or conversion of the reactive substances into an active form. While the conversion of a reacting substance into an active form may very well account for the effect of the solvent on reaction velocity in homogeneous systems, it must be shown what active form is produced and why one solvent produces more of it than another.

In conclusion, Prof. BANCROFT stated the study of organic reactions is by far the most likely to prove fruitful, and he listed tentatively sixteen problems which should be investigated.

Symposium on Colloid Chemistry

Dr. BANCROFT opened the quartet of papers discussing colloid chemistry with a résumé of phenomena having an electrotechnical aspect. So long as the suspended particles are all charged positively or negatively, they will tend to repel one another and will not coalesce unless the concentration is too high. Colloid solutions will be very sensitive to electrolytes having a readily adsorbable ion of the opposite charge from that which stabilizes the colloids. The formation of deltas is due primarily to the coagulation of the suspension by the electrolytes in the salt water. Migration of colloidal particles under electrochemical potential, cataphoresis and electrical endosmose, the functioning of a diaphragm, were discussed. Charged dust suspensions and their electrostatic precipitation were described in analogy to liquid suspensions.

SETTLING PROBLEMS

WILLARD A. DEANE, of the Dorr Co., spoke at length on "Settling Problems" and how these have been successfully solved.

The introduction of "continuous settling" has resulted in greatly increased application of sedimentation processes. The practical requirement of every settling problem involves two distinct processes, one clarification, the other thickening. The requirements for clarification are the minimum thickener area permissible with a continuous overflow of liquid of specified clarity. The requirements for thickening are a continuous discharge of thickened pulp of lowest permissible moisture content. In clarification problems the settlement of the finest particles is the governing feature. The settling properties of a pulp may be largely improved by a proper adjustment of conditions in processes prior to sedimentation.

Each settling problem is governed by specific conditions requiring independent study and analysis, and the most satisfactory solution often involves a study of processes and methods with a view of possible changes in certain conditions, so as to alter the physical character of the suspension and promote improved settling.

In the discussion of Mr. Deane's paper, the Chair, Dr. BANCROFT, called attention in particular to the author's description of the clarification of concentrated solutions. Deane's is the first good explanation he had seen to account for the fact that dilute solutions settle cloudy and thick or concentrated solutions clear. There is a sort of filtering effect taking place in the latter solutions, the coarser particles holding up the very fine ones. In the separation of cream from milk we have an upward filtering motion; and in a deep pan cream separates faster than in a shallow one.

GRAPHITIC ACID—A COLLOIDAL OXIDE OF CARBON

The third paper of the symposium was submitted by GEORGE A. HULETT and O. A. NELSON, of Princeton University, on "Graphitic Acid—A Colloidal Oxide of Carbon." After a careful survey of the investigations on graphitic acid carried out in the past, the authors reported on a series of experiments made to determine the relations of water to graphitic acid.

The translucent graphitic acid plates are made of an infinity of plates of excessive thinness. The relation of water to this substance and its variable properties are readily interpreted on the assumption that graphitic acid is a solid oxide of carbon with an exceptionally large surface covered with adsorbed water. The information available indicates formulas of the order C_3O or $C_{11}O_4$.

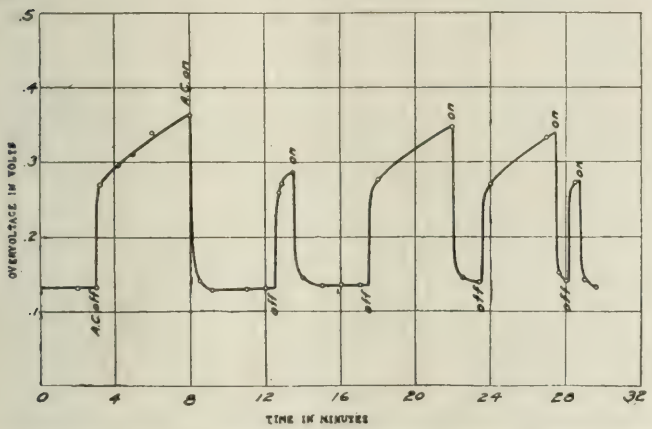
In discussing this paper, F. A. J. FITZGERALD referred to his years of investigation of a method of analysis for graphitic oxide without obtaining any positive results. He had made the best graphitic oxide from a sample lot of Irish coal; this oxide would swell up very appreciably during graphitization in the electric furnace. E. O. BENJAMIN called attention to the fluffy graphite that Mr. AYLESWORTH of the Edison Co. had obtained. The volume was about seven times that of any other graphite.

PROBLEM OF DETERMINING GRAPHITIC CARBON

W. A. SELVIG and W. C. RATLIFF, of the Bureau of Mines, Pittsburgh, Pa., reported upon a detailed investigation of the Problem of Determining Graphitic Carbon. No direct quantitative method for the determination of graphitic carbon in the presence of amorphous carbon has ever been developed before. Selvig and Ratliff tried out the Brodie and Staudenmaier methods ($H_2SO_4 + HNO_3 + KClO_3$) for the conversion of gra-

phitic carbon to graphitic acid on Alabama, Pennsylvania, Ceylon and Acheson graphites, and on mixtures of Ceylon and Acheson graphites with amorphous carbon in the form of anthracite and bituminous coal and coke. The Staudenmaier method (14 c.c. concentrated H_2SO_4, 6 c.c. concentrated HNO_3 and 18 g. $KClO_3$) was not applicable to substances containing relatively large amounts of amorphous carbon, as the reaction goes to explosive violence. Amorphous carbon in the form of anthracite and bituminous coal and coke when treated by the Brodie method (10 c.c. HNO_3 + 4 g. $KClO_3$ per ½ g. of sample) gave no graphitic acid in the case of the anthracite and bituminous coal. A slight amount of graphitic acid was, however, obtained from coke, this indicating the presence of graphitic carbon in coke. Graphitic acid cannot be made to come to constant weight by ordinary methods of drying, as the substance is very susceptible to varying humidity changes.

The Brodie method of conversion of graphite to graphitic acid can be hastened by a supplementary treatment with sulphuric acid and potassium permanganate. Carbon in the form of coal, coke, calcined anthracite,



SHOWING TYPICAL EFFECT OF ALTERNATING CURRENT ON OVERVOLTAGE

natural and artificial graphites gave varying amounts of CO_2 when treated with the Brodie mixture.

The graphitic carbon content as determined by conversion to graphitic acid by the Brodie and Staudenmaier methods and subsequent combustion gave low results as compared to direct combustion of the graphites. These differences were the least in the Ceylon and Acheson graphites and greatest in the Alabama and Pennsylvania graphites. They may be due to the differences in the physical characteristics of the graphites, such as flake structure. However, no satisfactory reason can be given why, when subjected to the same number of treatments with the same oxidizing mixture, Alabama and Pennsylvania graphites give a larger loss of carbon as CO_2 than do Ceylon and Acheson graphites.

Graphitic acid when treated with the Brodie mixture slowly gives off CO_2. It appears that when graphitic carbon is treated with oxidizing mixtures a series of oxidation products result, the end products being CO and CO_2. The maximum yield of graphitic acid is obtained under rather narrow limits as to temperature, time, and oxidizing reagents.

With Ceylon and Acheson graphite, in which the conversion of the graphitic carbon to graphitic acid proceeds at a comparatively rapid rate, the graphitic carbon content as estimated by the Brodie and Staudenmaier methods gave results which were within 5 per cent of the true graphitic carbon content. On the other hand, Alabama and Pennsylvania graphites, which required a prolonged treatment for conversion into graphitic acid, gave very low results, due, no doubt, to a larger loss of carbon as carbon gases resulting from complete oxidation to CO and CO_2. Carbon in the form of coke and partly calcined anthracite coal, though finely ground, required more treatments than pure graphitic carbon in the form of Ceylon and Acheson graphites.

The action of oxidizing mixtures on different forms of carbon offers an extended field for further scientific investigation.

In the discussion, Mr. FITZGERALD suggested that the methods as outlined by the authors might be applied to advantage to the different grades of carbon and graphite anodes on the market today.

Overvoltage—Dry Cells—Storage Battery

"The Effect of an Alternating Current on Hydrogen Overvoltage" was the title of a paper by H. M. GOODWIN and M. KNOBEL, of the Massachusetts Institute of Technology. They studied the overvoltage of hydrogen on platinum, lead and copper cathodes when alternating current was superposed on the direct electrolyzing current. The effect of varying the alternating current was also studied, the effect of its frequency and the power factor. The effects seem in general to be due to the oxygen liberated on the cathode by the reverse wave of the alternating current. The magnitude of this depolarization appears to be independent of the electrodes and of the current density, and determined primarily by the ratio of alternating to direct current used. The effect increases slightly as the frequency decreases, but results would indicate that it is practically independent of the power factor.

H. D. HOLLER and L. M. RITCHIE reported their observation of a marked difference in potential of manganese dioxide electrodes made of natural ores and the chemically prepared oxide, the former giving twice the voltage and varying as a logarithmic function of the hydrogen ion concentration. The prepared oxide showed no relation to the hydrogen ion concentration. The cause of this difference has not been investigated. At least a portion of the polarization of a dry cell during discharge may be explained as being due to a layer of electrolyte on the surface of the electrode impoverished in hydrogen ions.

A careful investigation of "The Reactions of the Lead Accumulator" was reported upon by Prof. D. A. MACINNES. The research was carried out by himself and L. Adler and D. B. Joubert at the Massachusetts Institute of Technology and the University of Illinois. The amount of sulphuric acid consumed during the discharge of a lead accumulator was measured in order to determine whether 2 or 1 g. equivalents of acid disappear per Faraday passing and in order to decide between Gladston and Tribe's formula for the chemical reaction or that advanced by Fèry. The result was intermediate of the two. Careful chemical analyses of the oxide formed during charging show it to be certainly PbO_2. The chemical potential of the oxide on the positive plate was also found identical with that of chemically prepared PbO_2 and electrically precipitated PbO_2. The author suggested tentatively that intermediate oxides, for example Pb_3O_4, or basic compounds, for example $(PbO)_4.PbSO_4$ may be formed during discharge.

Arc Images in Chemical Analysis

The final paper of the Thursday morning session was that of William Roy Mott on "Arc Images in Chemical Analysis." Mr. Mott has been conducting a long series of highly interesting tests at the laboratories of the National Carbon Co.

Mr. Mott reproduced upon the screen some of the most characteristic arc images.

Dr. Bancroft, in discussion, complimented the author and ventured to say that the day was not far off when all analytical laboratories would be equipped with an arc image-testing outfit. Dr. Fink referred to the fractional separation of rare earths by the arc process and the comparative simplicity of this process as against any of the wet processes. Letters of commendation were received from Prof. Leonard of Wisconsin and Dr. Hillebrand of Washington.

Thursday Afternoon at Cambridge

Luncheon was served at the Walker Memorial Building of Massachusetts Institute of Technology, Cambridge, and an opportunity was afforded the members to inspect the splendid new buildings.

A New Cyanide

A technical session was held at the Institute from 2 to 4:30. The first paper was that of the incoming president, W. S. Landis, on "A New Cyanide" (see Chemical & Metallurgical Engineering, vol. 22, No. 6, Feb. 11, 1920, p. 265).

In discussion, L. E. Saunders of the Norton Co. gave a brief account of his early experiments on cyanamide and cyanide carried out in the electric furnace. With barium salts he had obtained fairly high efficiencies. The barium cyanide-cyanamide mixture was fused together with soda ash; the output of NaCN was high enough to offer commercial possibilities, but basic patents interfered.

Carbon in Iron

Dr. T. D. Yensen, of the Westinghouse Research Laboratory, presented a paper on a highly efficient method of determining very small amounts of carbon in iron.

The ordinary method of determining carbon in iron and steel consists in burning the sample with free oxygen, absorbing the CO_2 by means of KOH and weighing the KOH bulb before and after. In order to eliminate the errors due to absorption and weighing, the new method substitutes freezing out the CO_2 with liquid air and allowing it to expand into a known volume and noting the increase in pressure. In order to differentiate between the carbon existing as adsorbed CO or CO_2 and that existing in combined form, the method involves two heatings, one to 600 deg. C. in vacuo, and the other to 1,000 deg. or higher in oxygen. Extra precautions are also taken to eliminate errors due to other sources, so that by this method carbon can, if necessary, be determined with an accuracy of ± 0.0001 per cent.

Dr. Yensen's vacuum method gave rise to much favorable comment and was generally conceded to be one of the greatest advances in carbon analysis. Dr. A. S. Cushman of Washington pointed out that one of the great advantages of the Yensen method lay in the fact that we could now readily determine separately the three kinds of gases present in iron and steel: (1) blow-hole gas; (2) gas held in solid solution, and (3) "combined" gas, i.e., nitrides, carbonyls, carbides, etc. Nitrogen has a very deleterious effect on the quality of the steel; and furthermore, the effect of nitride nitrogen is distinct from that of dissolved nitrogen.

Other papers presented during this session included "The Influence of Enclosed Slag on the Corrosion of Wrought Iron," by L. T. Richardson, and "The Embrittling Effects of Cleaning and Pickling Upon Carbon Steels," by S. C. Langdon and M. A. Grossman, abstracts of which will be published in subsequent issues of Chemical & Metallurgical Engineering.

Electrolytic Calcium—Chromium—Bronze

P. H. Brace, of the Westinghouse Co., submitted an account of experiments on "The Electrolytic Production of Calcium," in which a new modification of Goodwin's moving-cathode cell was developed. Pure calcium chloride, properly dehydrated, was found to be the most satisfactory electrolyte. The product contained 1.08 per cent of chlorine and very small quantities of carbon.

"Electrolytic Chromium" was the title of a highly interesting paper contributed by George J. Sargent, of New York.

Brief allusion was made to the history of the deposition of chromium, including some unpublished work done by Skillman at Cornell University. Details were given of the electrolysis of various mixtures of chromic sulphate and chromic acid, showing that the yield of chromium from chromic acid solutions is greatly increased by the addition of chromic sulphate. Tabulated records were included of experiments with rotating cathodes, as compared with stationary cathodes, and investigations of the most favorable temperatures, and strengths of solution and mixtures, and current densities. Some theorizing was indulged in concerning the deposition of chromium with two different valences, 3 and 6, from chromic acid, chromic sulphate plating solutions. Very good deposits of chromium were obtained from chromic acid solutions containing small amounts of chromic sulphate. Low temperatures yielded fair ampere-hour efficiencies at comparatively low current densities. A deposit up to 1.25 cm. thick was obtained. The chromium plating is extremely resistant to corrosion by air, moisture, and many chemicals.

During the discussion of the paper, Dr Bancroft, under whose direction the research had been carried out, emphasized that the quality of the chromium deposit was very much dependent upon the current density. Attempts were made to produce a chrome-steel surface on iron by heating the plated iron in hydrogen. But very high temperatures were required to bring about good alloying and the scheme did not prove to be practical. F. S. Weiser, of Waterbury, suggested that a chromium-plated nickel wire might be used in place of the nickel-chromium alloys.

"Bronze Plating" was investigated and reported upon by Prof. F. C. Mathers and Stanley Sowder, a student of his at Indiana University. They found that bronze can be deposited from a bath containing potassium hydroxide 5 per cent, potassium cyanide 0.5 per cent, ammonium stannic chloride 0.38 per cent and potassium copper cyanide 1.5 per cent. Satisfactory corrosion of bronze anodes is obtained, using a temperature of 40 to 50 deg. C., and current density of 0.4 amp. per sq.dm. (3.75 amp. per sq.ft.).

Refractories; Their Physical Characteristics

The Research Laboratory of the Carborundum Co. presented two papers on refractories by M. L. HARTMANN and O. A. HOUGEN.

SPALLING LOSSES

The first paper was on "Spalling Losses" and covered comparative tests of the resistances of twelve different kinds of refractory bricks exposed to rapid cooling by an air blast after heating to 1,350 deg. C. This cooling was repeated up to ten treatments with nine bricks, while three were completely disintegrated at the seventh, fourth and third treatments. The results of all tests are summarized in the following table:

	Spalling at End of	Per Cent
1. Bonded carborundum (carbofrax C)	10th cooling	0.3
2. Bonded carborundum (carbofrax A)	10th cooling	6
3. Bonded carborundum (carbofrax B)	10th cooling	8
4. Grade A fireclay	10th cooling	9
5. Recrystallized carborundum (refrax)	10th cooling	12
6. Bauxite	10th cooling	43
7. Zirconia (natural)	10th cooling	53
8. Grade B fireclay	10th cooling	65
9. Grade C fireclay	10th cooling	90
10. Chrome	7th cooling	100
11. Silica	4th cooling	100
12. Magnesia	3d cooling	100

From five to ten bricks were used in each test. These were purchased in the open market and undoubtedly do not give absolute results for the various types of refractories. The general order of magnitude of spalling is probably correct, however.

COMPARATIVE COLD AND HOT ABRASION TESTS

The second paper was based on "Comparative Cold and Hot Abrasion Tests." These tests were made on different kinds of refractory materials, at ordinary temperatures and at 1,350 deg. C., by a carborundum cutting wheel under a constant pressure, and measuring the depth abraded in a given time. The results are summarized in the following table. While the figures are only roughly quantitative, they indicate the general relative resistances of these materials to abrasion.

TESTED HOT (1350 DEG. C. AT START)
(5-MINUTE PERIOD)

	Abrasion Inches
1. Bonded carborundum (carbofrax C)	0.01
2. Bonded carborundum (carbofrax A)	0.01
3. Bonded carborundum (carbofrax B)	0.03
4. Bauxite	0.04
5. Zirconia (natural)	0.06
6. Recrystallized carborundum (refrax)	0.07
7. Grade C fireclay	0.07
8. Grade B fireclay	0.09
9. Grade A fireclay	0.11
10. Chrome	0.27
11. Magnesia	12.50
12. Silica (lime bonded) spalled too badly for measurement.	

In discussing these two papers, F. A. J. FITZGERALD, of Niagara Falls, referred to the change in crystalline structure of certain bricks, in particular magnesite, which would naturally effect the spalling tendency. Furthermore, since the heat conductivity of the various bricks tested is widely different, the carborundum wheel test for abrasion does not seem to be satisfactory. Possibly a sand-blast test would be more reliable. Messrs. RICHARD, SAUNDERS and BANCROFT also participated in the disscusion.

The Smoker

The smoker was a distinct success. It was held in the laboratory of Arthur D. Little, Inc., beginning with a general inspection with incidental "exercises," which we shall describe later, and concluding in the assembly and lunch room. The tour began in the chemical museum on the main floor. This contains a large number of rare and interesting specimens as well as an illuminating exhibit of successive raw, intermediate and finished products of a great variety of industries. It is also so arranged as to show many things that could and should be done, for profit as well as for the improvement of human conditions, provided only the necessary research were undertaken and carried to a definite conclusion. It would be hard to find a better demonstration of the achievements of research on the one hand or of the amazing lack of initiative in industry to accomplish results that are at once available and greatly needed by this very means.

After a look through the administration offices the guests entered the basement, inspected semi-commercial scale apparatus and saw the experimental paper mill in operation, making A. D. L. filter paper; the entire plant being operated with distilled water. Following this the research laboratories, library and analytical laboratories were all visited, except the extraction room in which over-night work was in process. Then ensued a kind of competitive examination in olfactics, or of the nose efficiency of persons present.

AN EXAMINATION IN OLFACTICS

In one of the large rooms four tables were placed upon each of which were twelve similar bottles, corked and labeled with numbers. Each contained cotton wool moistened with 2 c.c. of an odoriferous body, and blanks were provided with spaces for the person's name and answers to be filled in. The key, which was known only to a committee of the staff, was: 1, almond extract; 2, kerosene; 3, oil of lime; 4, turpentine; 5, amyl acetate; 6, acetic acid; 7, carbon tetrachloride; 8, Worcestershire sauce; 9, carbolic acid; 10, ethyl alcohol; 11, oil of sassafras, and 12, vanilla extract. Nearly 80 per cent answered three-quarters of the numbers correctly, seven made only one mistake and only one, Dr. Alcan Hirsch of New York, gave the right answer to all twelve. He received the prize of a gold-headed silk umbrella. Some of the errors were interesting. Carbon bisulphide, iodoform and eucalyptol were mistaken for phenol, lactic acid for alcohol and acetic acid, menthol for turpentine and a majority thought sassafras was wintergreen. One wrote after No. 10 (alcohol), "familiar but cannot remember."

HUNTING WITH A CAMERA IN NEW BRUNSWICK WOODS

At about 9:30 the company repaired to the assembly room, where, after some lusty singing by the assembled 200 guests and some original songs by an employee of the laboratory written in the trenches in France, Lyman Underwood, a biologist of the faculty of the Institute of Technology, gave an illustrated talk on hunting with a camera in the New Brunswick woods. It was a very lively and interesting address and it made nearly everybody want to go and do likewise without delay. In introducing Mr. Underwood a member of Dr. Little's staff told a chemical story that should be profitable to those young men who want to study chemistry and nothing else. It seems a chemist of this sort was invited by an astronomer to look through his telescope with a field of a nebula in focus. "Huh!" exclaimed the chemist as a multitude of suns appeared, "the damned thing's colloidal!"

Refreshments were served at 11 o'clock and the occasion was acknowledged to have been one of the best smokers ever.

Symposium on Electrically Produced Alloys

The Friday morning session was a joint session with the American Institute of Electrical Engineers, and was held in the Copley Plaza Hotel. Dr. H. E. HOWE, of the National Research Council, introduced the subject with a brief discourse on "The Fundamental Problems in Alloys Research." A good deal of investigation is required, Dr. Howe said, in order to complete the published data on standard alloys. Likewise the testing of non-standard alloys should be undertaken and detailed physical and chemical properties tabulated and published. The corrosion problem is a very large one and has only been partly solved. Phase rule diagrams of ternary alloys are badly needed; very little has been published in this line. The effect of occluded gases on metals, specific heats of many metallurgical compounds, and best alloys for die casting are some of the other important problems that await solution. In conclusion Dr. Howe referred to the newly organized Alloys Research Association, which will devote its efforts initially to an informational service.

MANUFACTURE OF FERRO-ALLOYS IN THE ELECTRIC FURNACE

"The Manufacture of Ferro-Alloys in the Electric Furnace" was the title of a paper presented by C. B. GIBSON of the Westinghouse Co.

He stated that the demand for ferro-alloys is governed, to a large extent, by the requirements of the iron and steel industry. As specifications for ordinary, tool and alloy steels, and also castings, are becoming more rigid, the steel maker is depending on ferro-alloys to meet these requirements. The alloys in general use for deoxidizing are ferromanganese, ferrosilicon, etc. The alloys used for imparting to steel certain properties are ferromanganese, ferrochromium, ferrotungsten, ferromolybdenum, ferrovanadium, ferro-uranium, ferrotitanium, ferrozirconium, etc. After discussing briefly the specific uses of these alloys, the author gave some data in regard to power and raw material consumption in the manufacture of some ferro-alloys.

In laying out new furnace installations, or in planning to improve the operating conditions of existing ones, a careful study is essential of the problems relating to the bus and cable layout. Relatively the problems involved in 25-cycle installations, for the same size furnace, are not as serious as for 60-cycle, for the reason that maximum energy that can be fed into a constant voltage circuit at different frequencies is inversely proportional to the frequency. In other words, where a 10,000-hp., 60-cycle furnace is about the limiting size for a well-designed furnace and bus layout, 22,000 hp. is the corresponding size for a 25-cycle furnace.

In the discussion of Mr. Gibson's paper it was pointed out that the United States had two serious competitors in the ferro-alloy field—Canada and Norway. Dr. BANCROFT asked whether it was possible to predict at this time whether 25- or 60-cycle current is going to win out. Mr. Gibson replied that at present it was difficult to say; similarly, the limiting size of furnace cannot be predicted today; 3,000-kw. furnaces appear to be amply large. Dr. RICHARDS referred to the blast furnace as a competitor of the electric furnace and believed it to be possible to make 50 per cent ferrosilicon in the blast furnace if oxygen-enriched air were used. Dr. FINK in reply stated that highly concentrated electrical energy was usually cheaper than highly concentrated chemical energy and 50 per cent ferrosilicon made in the blast furnace would be comparatively costly.

DEVELOPMENT OF FERROVANADIUM METALLURGY

Another paper of the symposium was presented by B. O. SAKLATWALLA, general superintendent of the Vanadium Corporation of America, on "The Development of Ferrovanadium Metallurgy." The speaker referred to the modern introduction of vanadium into large-scale metallurgical practice, in armor plate and special steels. He described the methods of reducing vanadium compounds to metal by silicon in the electric furnace; by the alumino-thermic process, and finally by carbon.

In the discussion of Mr. Saklatwalla's paper GEORGE M. BERRY, of Syracuse, brought up the question of the future supply of vanadium and its steadily increasing cost. According to Mr. Saklatwalla there is only one deposit of importance, that of Peru.[1]

The supply has not been able to keep pace with the demand. Replying to Mr. GILLETT'S question, it was brought out that the percentage of carbon in the new carbon-reduced ferrovanadium is no higher than that of the former aluminum-reduced ferrovanadium (carbon derived from the lining). As to the somewhat higher silicon content found by Mr. Berry in the new product, Mr. NORRIS of the Vanadium Corporation stated that there is no objection to this silicon content in electric-steel manufacture, since the silicon can be slagged off readily. In the crucible process there might be difficulty in keeping the silicon content of the tool steel down. Others participating in the discussion were Messrs. BANCROFT, FINK and RICHARDS.

MANUFACTURE OF STELLITE

Mr. ELWOOD HAYNES of Kokomo, Ind., contributed an account of the present day manufacture of stellite, the well known tool steel. He referred also to many of the very remarkable physical and chemical properties. Dr. S. A. TUCKER of the Chemical Foundation inquired regarding the high price of the alloy and ventured to state that the present limited use of the alloy was due to its cost alone. Dr. FINK referred to Mr. Haynes' difficulties in the past in attaining uniform results when the alloy was made in an oil- or gas-fired furnace. Today, however, stellite is made in the electric furnace and the product is absolutely uniform in quality, strength and hardness. Dr. RICHARDS added that when making armor plate by the open-hearth process, 50 per cent of the chromium is lost.

FERROSILICON AND OTHER SPECIAL ALLOYS

"Ferrosilicon" was the subject of a paper by F. A. RAVEN, of the Canadian Ferro-Alloys, Ltd. Ferrosilicon is one of the most important of all ferro-alloys. The paper included a very interesting account of the various grades of ferrosilicon; description of the older and modern processes of manufacture; methods of grading; various applications of the alloys; and discussion of the electric furnaces best adapted to alloy manufacture.

RALPH M. MAJOR, of the Driver Harris Co., Harrison, N. J., gave an illustrated talk of the manufacture of nichrome, climax, invar and other special alloys made by his company.

In the discussion Dr. BANCROFT described the nichrome tubes that were used by the Government dur-

[1] See *Eng. and Mining J.*, April 3, 1920, p. 814.

ing the war for heating and activating nut charcoal. Messrs. TUCKER and WEISER discussed the forgeability, hardness and resistance to wear at elevated temperatures of the alloy nichrome. Mr. MAJOR said that there was not yet very much data available along these lines, but that tests are under way. Nichrome will stand about as much wear, when hot, as steel. It can be made very hard by working but not by heat treatment.

The Anaconda Copper Mining Co.'s experience in the electrical production of ferromanganese was related by E. S. BARDWELL, of the Great Falls staff.[2]

HIGH-SPEED STEEL

Of the complex alloys made in the electric furnace, high-speed steel is among the most important. A detailed account of its manufacture was presented by ROY C. MCKENNA, president of the Vanadium Alloys Steel Co. By the electric-furnace process the vanadium content of high-speed steel can easily be maintained within much narrower limits than by the crucible process. The average power consumption of a 3-ton heat of high-speed steel melted in a 3-ton Heroult furnace is 1,000 kw.-hr.; 40 lb. of carbon electrodes per heat; 80 heats per lining.

In discussing Mr. McKenna's paper, Mr. NORRIS reported that ferrovanadium with 20 per cent silicon had been successfully used in the electric furnaces. F. W. BROOKE, of Philadelphia, emphasized the importance of deoxidizing the slag before adding the ferrovanadium. Formerly too little attention was paid to this point.

"The Electrolytic Production of Ferrocerium" was described by Dr. ALCAN HIRSCH, of New York. The raw materials for cerium are the residues of the gas mantle industry. These are purified and the cerium salt is introduced into a fused bath. During electrolysis the current and voltage is carefully controlled and regulated. The metal is cast into small 8-in. molds. This is next alloyed with iron (30 per cent) or magnesium or copper. The ferrocerium is used in the manufacture of pyrophoric lighters. Dr. Moldenke has tried it out as a deoxidizer for steel, producing a very soft product, practically free from gas and with little internal shrinkage. The magnesium-cerium alloy is used for miners' lamps, where the flame effect is more desirable. Tests made on copper bars showed that the addition of a small percentage of cuprocerium to the molten copper increased the ultimate strength of the rolled or drawn metal from 25,000 lb. per sq.in. (without Ce) up to 26,740 (with Ce addition); elongation 28.4 and 33.5; and reduction in area, 23.6 and 37.8 respectively.

The paper was discussed by Messers. GILLETT, BULLOCK, BENJAMIN, FINK and BRAID.

"The Magnetic and Electrical Properties of Iron-Nickel Alloys" was the title of an A.I.E.E. paper submitted by Dr. T. D. YENSEN, of the Westinghouse Co. He reported upon a series of careful experiments on the permeability and hysteresis loss of Fe-Ni alloys, a paper which will be abstracted in a subsequent issue of CHEMICAL AND METALLURGICAL ENGINEERING.

W. S. LANDIS
New President of the American Electro-Chemical Society

ELECTRICAL PROPERTIES OF TITANIUM ALLOYS

Prof. M. A. HUNTER and J. W. BACON, of the Rensselaer Polytechnic Institute, investigated "The Electrical Properties of Titanium Alloys." They found that the addition of titanium to iron improves the magnetic quality of the iron. Alloys of titanium with nickel, copper, nickel-iron and nickel-copper were made. The resistances of these materials are only moderately high for additions of titanium up to 5 per cent. Beyond this point the alloys are exceedingly hard to draw.

Dr. YENSEN, in discussing Hunter and Bacon's paper, referred to experiments he had carried out on ferro-titanium alloys. His results seemed to show that there was no advantage in using titanium. In general better results were obtained with silicon and aluminum than with either titanium or boron.

Exhibit of Electrically Produced Alloys

In conjunction with the symposium a very attractive and instructive display of the various alloys produced in the electric furnace and electrolytic cell had been arranged by R. P. HOMMEL. Among the novelties were sheets of electrolytically deposited brass (¼ in. thick) and brass-plated steel submitted by GEORGE HOGABOOM; a large sample of silicon-zirconium from the Electrometallurgical Co., Niagara Falls; and rods of ductile aluminum silicide (tensile strength 30,000; elongation 5 to 6 per cent) submitted by the Alpax Laboratories of Cleveland.

Fixation of Atmospheric Nitrogen

C. FRANCIS HARDING and K. B. MCEACHRON, of Purdue University, gave a detailed account of their experimental studies of the fixation of atmospheric nitrogen by the silent electric discharge (Paper published in the *Journal*, A.I.E.E., April).

Power for Electrochemical Purposes

The Friday evening session was likewise a joint session with the American Institute of Electrical Engineers. That most vital of all topics—power—was discussed by many of the chemists and engineers assembled. President C. TOWNLEY of the Institute presided. JOHN L. HARPER opened the discussion with a paper on "Power for Electrochemical Purposes." He confined most of his attention to developments, both past and future, in the eastern section of the country. Here was a potential power of 1,900,000 kw. At Niagara today there were 500,000 kw. developed.

ELECTRIC-FURNACE POWER FROM THE STANDPOINT OF THE CENTRAL STATION

E. A. WILCOX, in his dissertation on "The Electric-Furnace Power From the Standpoint of the Central

[2]This paper was published in full in this journal April 14, 1920, p. 681.

Station," reviewed the entire situation in detail. He believed that a small electric furnace operating rapidly is preferable to a slow large unit. Furthermore, frequent heats mean less floor space. Electric-furnace power has many advantages: large blocks, no close regulation of service voltage as is required in lighting service, and more constant and steady demand and supply than interurban car or street car service. As a rule three-phase power is to be recommended.

Power Problems From the Standpoint of the Furnace Operator

Wallace G. Berlin, of High Bridge, N. J., discussed "The Power Problems From the Standpoint of the Furnace Operator." He talked chiefly of the power requirements when melting cold charges in the steel furnace.

In the open discussion, F. Hodson, of Philadelphia, recommended the installation of graphic meters very highly and considered it poor practice to overload the furnace. Mr. Benjamin urged a wider use of off-peak power for various electrolytic processes. Dr. Hering strongly favored the use of small furnaces at high speed on account of the much higher economy. Mr. Gail referred to the frequent unsatisfactory tariff contract. H. A. Winne said that a series of electric furnaces could be operated at a time very cheaply if a fixed schedule was adhered to. Mr. Hess favored the cold charge for the highest quality electric steel.

Automatic Control of Arc-Furnace Electrodes

"Automatic Control of Arc-Furnace Electrodes" was the title of J. A. Seede's paper. He described and illustrated the regulator he invented at the Schenectady works and referred briefly to numerous installations which had been operating satisfactorily for the past ten or twelve years. In contradistinction to the Thury regulator, which is of the intermittent control type, the Seede regulator is of the continuous control type. Provisions are made in case power is shut off completely. The close regulation obtainable was strikingly demonstrated by a series of charts from a curve drawing instrument connected into the circuit of an electric alloy steel furnace.

Other Papers

Harvey A. Winne of Schenectady presented a paper on "Reactors for Electric-Furnace Circuits."

C. T. Maynard described the plant of the Rumford Falls Power Co. in Maine, and pointed out the many advantages of this "Location for a New England Electrochemical Plant." About 35,000,000 kw.-hr. per year are available for immediate use as continuous primary power and about 40,000,000 kw.-hr. per year more of secondary power.

F. F. Fowler presented a discourse on "The Water Powers of the Pacific Coast." He discussed in detail the coastal rainfall, cause of present power shortage, Columbia River power development (estimated price, $15 per hp.-yr. on the basis of immediate sale of all the power), availability of raw materials, etc. Puget Sound is today the most favorable locality. In California the net minimum cost is $32 with a power factor 95 per cent and a load factor of 100 per cent.

The final paper of the symposium was that of Dr. J. W. Beckman, of San Francisco, on "Power Developments in Scandinavia." Dr. Beckman showed how active has been the development of water power in Scandinavia, fostered by wiser legislation on the subject than in the United States.

Visits to Industrial Plants

On Friday afternoon the members were the guests of the General Electric Co. and an interesting and instructive tour was made through the River Works and the old Thomson Houston plant on Federal St., Lynn. Of special interest was the inspection of the Heroult electric furnace in the steel foundry which was in "full blast."

On Saturday afternoon the plant of the Huff Electrostatic Separator Co. of Arlington was visited. William E. McKee of the company had arranged a very striking display of some of the results obtained with the separator and demonstrated the actual working of the apparatus. Of special interest was the concentration of graphite from native Alabama and Pennsylvania ores resulting in a high-grade product "Electrophite," used in the manufacture of plumbago crucibles. Other noteworthy separations were those made on Florida sands resulting in a 98.5 per cent TiO_2 product on the one hand and a 97.8 per cent ZrO_2 product on the other; and separation of zinc from gold, silver, lead, copper and iron in complex ores.

Saturday Morning at Harvard University

In his address of welcome, Prof. T. W. Richards referred to Benjamin Thompson's (Count Rumford) activities and pointed out that his early lecture notes were still preserved at Harvard. The first paper on the program was that of Joseph W. Richards on "The Söderberg Self-Baking Continuous Electrode."

Briefly, this arrangement calls for a mechanism situated on a working floor directly above the furnace, which forms and feeds the vertical electrodes just as fast as they are consumed on the lower end by the furnace.

This paper aroused considerable interest and was admitted to be one of the most important of the meeting. A member of the Southern Ferromanganese Corporation pointed out that three of its electric furnaces are being equipped with Söderberg electrodes and that Mr. Swann is fully confident of success. The electrodes are 32 in. in diameter and will be in operation next month. In reply to questions put by Messrs. Tucker and Saunders, Dr. Richards stated that the electrical resistance of the hard-baked Söderberg electrode was the same as that of the ordinary electrodes of today. As regards the smoke due to the binder, pitch and tar, this does not vitiate the atmosphere of the foundry, since it is forced downward into the furnace and is there consumed. Furthermore, the baking of the Söderberg e'ectrodes proceeds so very slowly, about one meter per week, that there is very little smoke produced per unit time. As regards possible iron contamination from the metal casing of the electrode, it was found by actual test that in calcium carbide furnaces the product contained but 0.2 per cent Fe. If the Söderberg electrode were to be used for aluminum furnaces, an aluminum casing could easily be substituted for the iron casing.

Synthetic Electric-Furnace Cast Iron

Charles Albert Keller, director of Keller & Leleux of Paris, contributed an interesting illustrated account of the production of "Synthetic Electric-Furnace Cast Iron," substantially the same as was published in Chem-

ICAL & METALLURGICAL ENGINEERING, vol. 22, p. 83. In the disscussion of Mr. Keller's paper, F. W. BROOKE, of the Electric Furnace Construction Co. of Philadelphia, emphasized the difficulties in obtaining high carbon cast iron from melting steel turnings in the electric furnace.

STEP INDUCTION REGULATOR FOR ELECTRIC FURNACES

PHILIP B. SHORT, of the Westinghouse Co., presented a brief paper on a new "Step Induction Regulator for Electric Furnaces." The equipment consists of a combination induction type regulator, a selector switch, a transformer switch, a series transformer and a suitable panel for meters and switches. Photographs were shown of equipment recently designed for twenty electric zinc furnaces in Norway.

L. E. SAUNDERS congratulated the company upon the design and production of this new regulator and felt convinced that with the introduction of this regulator a great saving in cost of operation could be looked forward to.

EVOLUTION OF THE ELECTRIC BRASS FURNACE

The next paper, by H. M. ST. JOHN, of the Detroit Electric Furnace Co., on "The Evolution of the Electric Brass Furnace," gave rise to a very spirited discussion.

Mr. St. John divided electric furnaces applicable to brass melting into three groups and discussed the evolution of commercial types in each group.

The indirect resistance type, in which heat is generated in a resistor and transferred by radiation or conduction to the metal to be heated, resulted from the tendency of the first designers to copy combustion furnaces. Various resistors have been employed in the electric crucible furnace, but none have met with marked success. A recent addition to this group is the high-tension, high-frequency induction furnace in which the walls of the crucible itself are electrically conducting and serve to heat the contents during the period while the metal is still solid. By placing an incandescent resistor in the top of the furnace, crucibles may be dispensed with, and the design simulates that of an open-hearth furnace. One successful furnace employs an overhead granular resistor contained in a nearly circular refractory trough.

In the induction- or direct-resistance type the heat is generated by the direct resistance of the metal itself. These furnaces utilize the pinch-effect phenomenon, the latest modification being the vertical-ring induction furnace, which is recommended only for 24-hr. operation melting yellow brass.

With arc furnaces, the heat is transferred to the metal directly or indirectly by conduction or radiation. Volatilization and oxidation losses are high in the direct-arc type, so this has given way to indirect-arc furnaces which are either rocking or rotating for the purpose of maintaining uniformity of temperature throughout the molten bath.

A consideration of what the brass foundryman could expect from the use of electric furnaces brought out the following data in regard to energy consumption:

The consumption of electric energy under average conditions of 8- to 10-hr. operation is as low as 240-kw.-hr. per short ton for yellow brass, and 275 kw.-hr. per ton for red brass, in the induction or arc furnaces. In 24-hr. operation figures as low as 200 kw.-hr. per ton or less have been obtained. Less efficient furnace types use from 400 to 500 kw.-hr. per ton, depending upon conditions.

Messrs. FINK, WINDER, CROSBY, TUCKER, GILLETT, CONE, WEISER, BAILY, HERING and RICHARDS participated in the discussion. The main point at issue was the kilowatt-hour consumption per ton of yellow brass.

C. A. WINDER, of the General Electric Co., felt that Mr. St. John had not sufficiently emphasized the advantages of other than arc type brass furnaces. The low zinc losses of the resistance-type furnaces due to lower temperatures of operation, the cleansing action of the pinch and induction-type furnaces, reducing the oxide contamination to a minimum, besides effecting a uniform temperature in the alloy itself, were points well worth while considering. At present there seems to be a field for every one of the five types of brass furnaces. L. E. CROSBY, of Detroit, submitted figures of performance of the "rocking" furnace. At ten different installations, melting 60-40 and 70-30 brasses, the consumption of electrical energy amounted to 240 kw.-hr. and less for an 8- to 10-hr. day. At one of the brass foundries a six months' record (8-hr. day) showed an average of 215 kw.-hr. per ton of brass. Bronzes containing 92 per cent copper require more power. As regards uniformity of temperature of the molten brass in the rocking furnace, direct measurements indicated a variation of not over 3 deg. C. The furnace rocks every 40 seconds and therefore big differences in temperatures do not obtain. Furthermore, contamination by oxides is very slight since the atmosphere in the furnace is a reducing one (CO gas). The actual tonnage turned out by the rocking furnace today is about twice that of any other type of brass furnace. H. W. GILLETT, of the Bureau of Mines, Ithaca, N. Y., cited the performance of an induction furnace at the American Brass Co.'s plant: A ton of yellow brass was melted in 174 kw.-hr.; 240 kw.-hr. was certainly not impossible, as Mr. Winder contended; every brass furnace ought to do as well as that. Dr. CARL HERING, of Philadelphia, put in a plea for the induction type or pinch effect furnace. An important point besides power consumption is low loss of zinc; in induction furnaces this loss is very low. Then there is the self-regulating feature of the induction furnace, whereby the temperature of the metal is kept within narrow limits. As soon as the temperature rises too high a small zinc bubble is formed and the circuit is broken. There are about eighty-four induction type brass furnaces in operation today. Mr. CONE of *Iron Age* added that today there are about 300 electric brass furnaces in operation, including all types.

F. S. WEISER, of the Scovill Mfg. Co., regretted that there were not yet available reliable relative data on the performance of the different types of brass furnaces, giving the life of linings, cost of operation, metal losses, etc., in each case. T. F. BAILY, of the Electric Furnace Co., Alliance, Ohio, said that in the operation of his resistance furnace 285 kw.-hr. is required per ton of yellow brass.

Dr. RICHARDS, in commenting on metal losses, pointed out that a saving of 1 per cent of zinc during melting was equivalent to about 64 kw.-hr. (1c. kw.-hr.) and that the theoretical power consumption for melting brass was about 130 to 150 kw.-hr. Zinc does not boil out of brass until the melting point of copper is reached.

In discussing "The Melting of Lead Alloys" in the electric brass furnace, Mr. WINDER stated that the induction furnace could not handle alloys higher than 2 per cent lead on account of rapid deterioration of the furnace lining. Mr. GILLETT quoted results obtained by Clamer in the induction furnace, showing that good results were obtained with 6 per cent lead alloys. Mr. CROSBY referred to the experience of the Michigan Smelting & Refining Co. It is melting a 26 per cent lead alloy in a 2,000-lb. rocking arc type furnace with a maximum deviation of lead of 0.6 per cent Pb.

THE ELECTRIC FURNACE IN IRON AND STEEL METALLURGY

The next paper was presented by LEWIS B. LINDEMUTH, of New York, on "The Position of the Electric Furnace in Iron and Steel Metallurgy." He gave a detailed comparison between the physical and chemical characteristics and phenomena of the four steel-making processes, bessemer, open-hearth, crucible and electric-furnace. The advantages of the electric furnace he dwelt upon in detail and concluded that the electric furnace, when properly installed and operated, is metallurgically the best steel-making apparatus we have, and economically the cheapest.

In discussing the paper Dr. RICHARDS, of Lehigh University, ventured to predict that the day is not far distant when all steel will be finished in the electric furnace. As a piece of apparatus for refining or finishing steel, the electric furnace has no competitor. The duplexing and triplexing systems are gaining favor.

ELECTRIC ARC MELTING FURNACE AND THE CENTRAL STATION ELECTRIC COMPANY

"The Electric Arc Melting Furnace and the Central Station Electric Company" was the title of the next paper, presented by AUGUSTUS C. SMITH, of the Buffalo General Electric Co. Tests on arc furnaces with an Esterline graphic meter were made and very accurate records of the characteristic use of electrical energy were secured. Photographic copies of these graphic records were shown. Many of these reveal great surges which cause serious disturbances in the central station's lines. Mr. Smith pointed out, however, that with a certain amount of care in the operation of the electric furnace the surges can be practically eliminated.

In discussing Mr. Smith's paper Mr. COE felt certain that abnormally large surges could easily be eliminated by introducing automatic reactors into the circuit. Mr. NOYES outlined the very efficient system of the Detroit Edison Co. in supplying power to various electric foundries. Small substations are located at or near the electric foundry, and these substations are fed by 23,000-volt feeders, entirely separate from the lighting circuits.

ELECTRIC FURNACE AS APPLIED TO METALLURGY

A very valuable compilation of the literature of "The Electric Furnace as Applied to Metallurgy" was submitted by CLARENCE J. WEST, of the Arthur D. Little Laboratories. This compilation covers the years 1900 to 1919 and will be greatly appreciated by all students of electrometallurgy.

RESOLUTION OFFERED BY DR. RICHARDS OF LEHIGH AND VISIT TO THE T. W. RICHARDS LABORATORIES

In bringing the session to a close, Dr. RICHARDS of Lehigh offered a resolution embodying the hearty support of the American Electrochemical Society of the undertaking of the National Research Council in collecting and publishing its tables of critical physical and chemical constants, the Society recognizing full well the valuable aid to research and industry of tables of this kind. Dr. Richards of Harvard suggested that detailed references to all data be given; also references to values not included in the tables. Dr. Bancroft in reply assured the members that no effort would be spared in making the tables as complete as possible. The selection of the most probable value will in each case be left to an expert or group of experts. The National Research Council hoped to accomplish in the case of these tables what has been done in the past for atomic weight determinations.

Before adjourning for luncheon at Harvard Union Dr. T. W. Richards invited the members to visit his new laboratories, where measurements of highest precision are carried out. These laboratories are absolutely dust-proof and provisions are made throughout for the elimination of influences and effects that might give rise to inaccuracies in the use or operation of mechanical and electrical apparatus and instruments. There were buttons of the purest silver in the world, a large crystal of gallium and beautiful specimens of indium on display.

February Exports Show Decline

A decided drop in exports was the outstanding feature of the February foreign-trade statement issued by the Bureau of Foreign and Domestic Commerce, Department of Commerce.

February exports amounted to $646,000,000, the smallest since October of last year, against $722,000,000 in the preceding month of January and $585,000,000 in February of last year. Exports during the eight months ended with February were $5,231,000,000, against $4,383,000,000 in the eight months of last year.

February imports amounted to $467,000,000, against $474,000,000 in January of this year and $235,000,000 in February a year ago. Imports during the eight months' period ended with February amounted to $3,235,000,000, against $1,933,000,000 a year ago. The imports during these eight months, representing two-thirds of the current fiscal year, exceeded by $140,000,000 the imports during the entire fiscal year ended with June, 1919.

Bronze Powder and Metal Leaf Industry in Japan

The statement that the Japanese bronze powder and metal leaf industry, which was making rapid progress before the war, grew phenomenally as a natural result of the cessation of their competitors, appears in an issue of *Commercial Osaka.* Several new companies were formed, including one having a monthly capacity of 100,000 lb. of bronze powder in addition to producing copper and aluminum powders and gold leaf.

Co-operation (!) During Reconstruction

The Société des Mines de Potasse de Sainte-Thérèse sent to the Portland Cement Werke Wetterau, of Langfurt a/M., a letter requesting an offer of cement and received the following reply: "It is agreeable to us to note by your request that France is in a state of economic dependence and we decline to come to her aid."—*The Review,* March 15, 1920.

T.A.P.P.I. BANQUET AT HOTEL ASTOR, APRIL 14, 1920

Fifth Annual Meeting of T.A.P.P.I.

Address of Welcome Given by George Sisson, President of the American Paper and Pulp Association—Presidential Address by Raymond S. Hatch—Election of Officers—Social Features, Including Banquet at Hotel Astor

THE fifth annual meeting of the Technical Association of the Pulp and Paper Industry was held April 13 to 15 in the Waldorf-Astoria, New York City. It was well attended and the program was well arranged and interesting.

Tuesday was devoted to meetings of the various standing committees, and registration of members and guests.

Society to Publish Journal

The first general session began on the second day. Raymond S. Hatch, president of the association, spoke of the growth of the society, which now numbers 535, and of the work it has accomplished. He also suggested the need of a technical journal controlled and operated by the association. This paper is to be devoted to the transactions of the association and to contain such technical information as pertains to the paper industry. The matter was favorably acted upon and referred to members of the finance and executive committees to devise ways and means of carrying out the project.

Address of Welcome

George Sisson, president of the American Pulp and Paper Association, delivered an address of welcome in which he emphasized the excellent work of the National Association of the Pulp and Paper Industry, and expressed the desire, on behalf of the American Pulp and Paper Association, to co-operate in every way possible to further the good work.

The rest of the morning session was taken up with reports of the committees and the election of officers.

Election of Officers

Officers elected for the ensuing year are: President, Raymond S. Hatch, the Hamersley Manufacturing Co., Garfield, N. J.; vice-president, Robert B. Wolf, Aeolian Building, New York, N. Y.; secretary-treasurer, Thomas J. Keenan, 471 Fourth Ave., New York, N. Y.; executive committee, Raymond S. Hatch, chairman; Robert B. Wolf; Henry E. Fletcher, Fletcher Paper Co., Alpena, Mich.; Frederick C. Clark, American Writing Paper Co., Holyoke, Mass.; Henry P. Carruth, Mead Pulp & Paper Co., Chillicothe, Ohio; Royal S. Kellogg, News Print Service Bureau, 18 E. 41st St., New York City; George E. Williamson, Strathmore Paper Co., Mitteneague, Mass.

Wednesday afternoon and all day Thursday were devoted to the presentation and discussion of the various papers, and to symposiums, the nature of which will be reviewed in a later issue of Chemical & Metallurgical Engineering.

Wednesday evening at 7 o'clock the members gathered for a reception in the Hotel Astor, followed by a banquet in the East Ball Room.

Judge Charles F. Moore, as toastmaster, spoke in the highest terms of the work done by the association for the paper industry, and of the appreciation by the men in the paper field of the chemical profession for its labors. He brought out the fact that the future success of the paper industry depended upon technical research, and that the very existence of the operators in the future depended upon the work of the technical men, and therefore the operators should support their work both financially and morally.

Herbert Hoover was to have been a guest of honor at the banquet, but owing to pressure of the many demands upon his time, he was unable to attend. He did, however, send his regrets and appreciation to T.A.P.P.I. and wished the association success in its work.

Dr. William H. Walker, of the Massachusetts Institute of Technology, gave a few reminiscences of his experiences in the early days of paper making and then explained a plan which M. I. T. is using to disseminate among the industry the vast store of information now collected and available in the institution.

Need of Vocational Education

Dr. Charles Baskerville, of the College of the City of New York, commented on vocational education and the dearth of trained men in this country of managerial capacity. He said that the three great factors of our prosperity are raw materials, money and men, and that although the country had the two former it lacked the trained men. Vocational education is a scheme to meet, in a measure, this situation. Dr. Baskerville also compared man to an instrument capable of development and not a mere receptacle of knowledge.

Howard S. Neiman, of New York City, told how T.A.P.P.I. protected the paper industry, and encouraged young men to go into the business.

Course Prepared by Vocational Education Committee

George Carruthers, president of Interlake Tissue Mills, Ltd., Toronto, Canada, said that 90 per cent of the managers of the Canadian paper mills were Americans. He laid special stress upon a new series of textbooks and correspondence courses now being prepared by the Vocational Education Committee of the Pulp and Paper Industry. This course aims to educate the men in the paper industry to a clearer insight of their own work and its relation to the industry as a whole, and also to fit them for more responsible positions.

Mr. Chipman, president of the Canadian Pulp & Paper Co., gave an outline of the meeting to be held in Canada and cordially extended an invitation for all present to come.

The Human Factor in Industry

John Stadler, of Belgo-Canadian Pulp & Paper Co., Ltd., Shawinigan Falls, Canada, the last speaker on the program, seconded Mr. Chipman's invitation, and then spoke of the human factor in industry. He did not consider this element as a commodity with a nominal market price, but something infinitely more vital with latent and potential capacities, upon which the development of the industry depended. Too much emphasis has been laid on the material side of the question and not enough on the human. He would bring the development of the man power of the organization to a higher plane through well-directed vocational education and co-operation with the management.

Crude Phosphate Situation in France

Agricultural science and intensive farming being highly developed in France, that country is a large user of superphosphate. In 1913 France consumed, in the manufacture of superphosphate, 1,100,000 tons of crude phosphate, which was obtained from the following sources: Algiers and Tunis, 795,000 tons; United States, 145,000 tons; and France, 160,000 tons.

During the years of the war France imported the following quantities of crude phosphate: In 1914, 787,000 tons; 1915, 346,000 tons; 1916, 321,000 tons; 1917, 258,000 tons; and 1918, 247,000 tons. The decrease in the use of crude phosphate was due to the lack of transportation facilities and to the fact that sulphuric acid was required as an essential in war industries. Prior to the war the annual production of superphosphate in France amounted to 2,000,000 tons, an amount sufficient for French consumption and for the export of 50,000 tons. During the war capacity for production of sulphuric acid was doubled. A greater part of this increase in productive capacity will ultimately be employed in the manufacture of the superphosphate, but this is not practical at the present time, as vessels and rail accommodation are lacking for the transportation of phosphate and also of pyrites and coal.

The French Government allocated the African phosphate production for the year 1919 as follows: France, 700,000 tons; England, 247,600; Italy, 355,000; Portugal, 14,700; Belgium, 3,600; Switzerland, 5,500; Spain, 734,600; making a total of 1,400,000 tons. But of the total amount allocated for French use, namely, 700,000 tons, only 200,000 tons were imported in the first semester, owing to the impossibility of securing vessels for transportation.

The needs of various European countries for crude phosphate in the year 1919 were estimated as follows, according to the *Fortnightly Review*, published by the American Chamber of Commerce, at Paris: France, 1,100,000 tons; Italy, 600,000 tons; England, 400,000 tons; Spain, 200,000 tons; Belgium, 100,000 tons; Netherlands, 100,000 tons; Portugal, 50,000 tons; Scandinavian countries, 40,000 tons; Switzerland, 10,000 tons; total, 2,600,000 tons.

Exports and Imports of Chemicals

Exports of chemicals during February were valued at $13,209,935, according to figures compiled by the Bureau of Foreign and Domestic Commerce. Some of the items making up that total, as well as revised figures for February of 1919, are as follows:

EXPORTS OF CHEMICALS

	Feb. 1919 Lb.	Feb. 1920 Lb.
Acids:		
Carbolic	27,372	97,534
Nitric	26,136	34,003
Picric	71	718
Sulphuric	767,792	2,025,311
Benzol	228,852	107,460
Calcium carbide	1,098,033	1,142,185
Copper sulphate	893,238	97,635
Wood alcohol	11,912	177,388
	Value	Value
Total sodas	$ 1,943,796	$ 1,706,556
Total chemicals	12,234,579	13,209,935
Total dyes and dyestuffs	2,018,642	2,461,797
Medicinal and pharmaceutical preparations	1,530,786	1,594,135

Some of the import figures, as compiled by the Bureau of Foreign and Domestic Commerce, are as follows:

IMPORTS OF CHEMICALS

	Value	Value
Chemicals:		
Free	$5,516,840	$11,878,274
Duty	3,896,713	4,725,832
Coal-tar products	400,345	350,174
Gums	2,012,186	4,363,893

Genesis of Ferrite

Contrary to Commonly Accepted Ideas, the Ferrite in Hypo-Eutectoid Steels Is Not Extruded as a Shell to the Outside of Austenitic Kernels, but Exists as an Aggregation of Crystals Essentially Discontinuous and Originating at the Low-Carbon Nuclei of Solid Solution Grains

By FEDERICO GIOLITTI

THAT α and β iron have an essentially different crystalline habit, and that the excess constituent in hypo-eutectoid steel does not collect at the periphery of austenite crystals in slowly cooled clean steel, can be demonstrated by direct observation of the various phases of formation of the ferrite itself, evidently the most direct and surest method of attacking the problem. Such demonstration appears necessary and is worthy of emphasis on account of the great practical importance of granular structure in steel and because so many erroneous ideas on its genesis appear in the literature. Especially, in the light of his own experiments, must the present author take issue with the eminent American Dr. Henry M. Howe in the latter's conclusions that ferrite is expelled to the outside of austenite grains on slow cooling, an idea developed at length in a paper entitled "Life History of Network and Ferrite Grains in Carbon Steel," published in the *Proceedings* of the American Society for Testing Materials, 1911, vol. 11, p. 271, and in his recent book on "The Metallography of Steel and Cast Iron."

I have presented reasons for believing that β iron crystallizes in rounded grains as compared to very flat plates, the normal habit of α iron, in an article entitled "Crystallography of Alpha and Beta Iron" appearing in CHEMICAL & METALLURGICAL ENGINEERING, vol. 22, p. 585 (March 31, 1920). In the present paper, the microscopic evidence further supports the hypothesis there set forth, but the primary purpose now is to establish my contention that ferrite meshes are essentially discontinuous chains of crystals and do not outline the original austenitic grain boundaries.

First Appearance of Ferrite

A few years ago the present author, with the aid of N. Boyer, conducted a series of experiments on a very well made, clean steel of the following composition:

	Per Cent		Per Cent
C	0.62	S	0.02
Mn	0.58	P	0.03
Si	0.07		

Some results of these experiments were presented at the time before the Academy of Sciences of Turin[1]. This steel had been forged into a bar 30 mm. square. Six blocks, 25 mm. long, were then cut off and suspended in a salt bath at 900 deg. C. for 1 hr. At the end of that time the fire was drawn and the bath slowly cooled, under constant stirring. When the temperature had fallen to 750 deg. C., one of the pieces was quickly withdrawn and quenched in water at room temperature, the second cube quenched when the temperature had fallen to 740 deg. C., and so on by 10 deg. steps, the sixth being withdrawn at 700 deg. C. All samples were then reheated in a lead bath at approximately 575 deg. C. to transform the martensite into sorbite.

When examined, the pieces quenched from 750 and 740 deg. C. were found to show sorbite and troostite, with no ferrite accumulations of microscopic size, which, indeed, could have been predicted. Fig. 1 gives the appearance at 160 diameters of the piece cooled to 730 deg. C. and then quenched[2]. Here are seen the first crystallites of ferrite which have separated out of austenite during the brief range from 740 deg. (the approximate temperature of germination of ferrite for this composition) and the quenching temperature, at which the normal process of growth of pro-eutectoid material was suddenly interrupted. As will become more apparent in the later specimens, it can be seen that even near the germinative point the ferrite separates in small isolated masses showing no disposition to segregate at the austenite grain boundaries when these grain boundaries do not contain any producers of oxidizing gases such as slag inclusions—an important reservation to which I will return later in this series of articles. The random location of the first appearing ferrite is all the more impressive when Fig. 1 is compared to Fig. 2 from Howe and Levy[3], which shows excess cementite extruded to a true meshwork at crystalline boundaries. Howe and Levy's metal contained 1.45 per cent C, 0.16 per cent Mn. It was heated under borax in a graphite crucible in an injector gas furnace for 50 min. to 1,200 deg. C., then transferred to a bath of fused KCl + NaCl at 930 deg., contained in a 4.5-in. graphite crucible held in an electric tube furnace. This temperature then was slowly lowered, taking 9 min. to pass from 960 deg. C. (above the germinative temperature) to 885 deg. C. (below the germinative temperature), at which latter point it was water-quenched, then reheated to 400 deg. C. to sorbitize the martensite ground mass. Apparently the conditions of formation allow close comparison of the crystalline habit of the pro-eutectoid constituent.

Quenching my steel at 720 deg. C. allowed the process of segregation to develop under normal conditions for a much greater interval. As shown in Fig. 3, the ferrite accumulates about nuclei of crystallization representing low-carbon localities and certainly not in characteristic contours surrounding granular kernels where, as a matter of fact, by the inhomogeneity of the solid solution, the last-solidifying material is *highest* in carbon. Instead, the ferrite crystals maintain an individual isolation, from which, however, there appears an incipient formation of acute projections due to the plate-like habit of α iron (in turn responsible for Widmanstättian structure, and the needle-like ferrite often observed in unannealed forgings, as discussed at some length in the article mentioned in the second paragraph

[1]Vol. 48, p. 1.

[2]All micrographs are etched with 5 per cent picric acid in ethyl alcohol except Fig. 8 which is etched with HNO_3 in amyl alcohol.

[3]"The Life History of Pro-Eutectoid Cementite," International Congress for Testing Materials, 1912, vol. 2, p. 1.

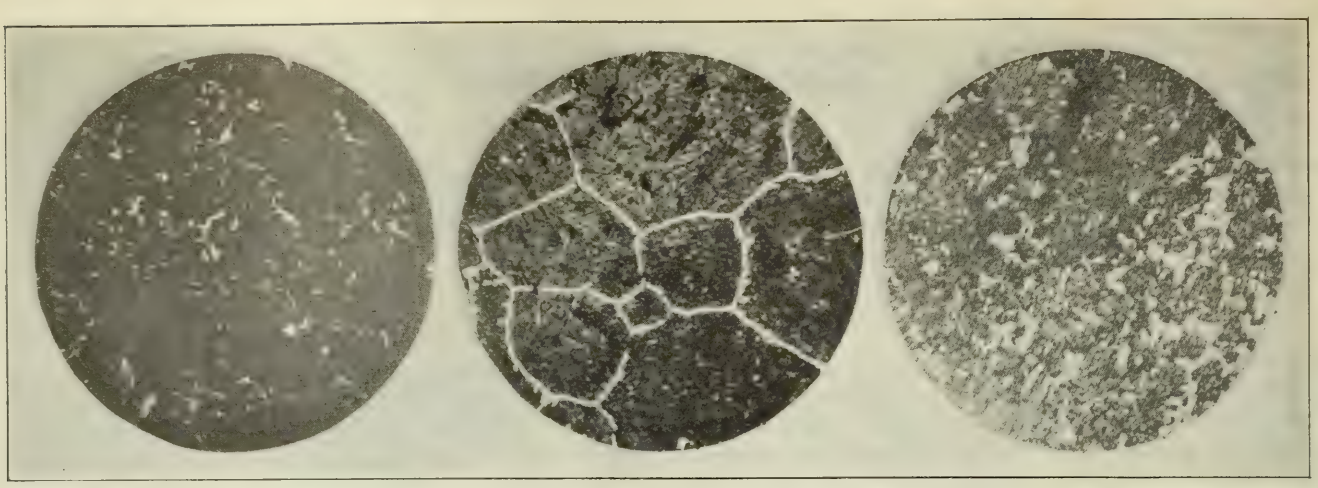


FIG. 1. Ferrite nuclei in 62-point carbon steel; quenched from 730 deg. C. × 160

FIG. 2. First precipitated cementite in 1.45 per cent carbon steel. × 50. (Howe and Levy)

FIG. 3. Ferrite nuclei, after further growth; quenched from 720 deg. C. × 160

of this paper). In this particular steel the first iron to precipitate came down as β iron, above the range MO of the iron:carbon diagram, at low-carbon spots containing considerably less carbon than the average analysis. On further cooling past the beta to alpha transformation, excess iron is precipitated as ferrite with its characteristic plate-like crystallization. Left to itself, such ferrite would appear in a rectilinear meshwork much like the warp and woof of woven cloth, but it is subjected to the additional attraction exerted by the pre-existing nodules of precipitated iron[4]. Its final form therefore is the resultant of these two forces —its own lamellar crystallinity, and the attraction of pre-existing accumulations of ferrite—and at the end the appearance is that of rough approximation of cell walls, much interrupted in their continuity.

Examination of Fig. 4 (quenched from 710 deg. C.) substantiates more clearly the above deductions. Here again are nuclei of ferrite, with their characteristic acute protuberances, but developed in size and distinctness owing to the longer interval of growth. Examined less in detail, but in general aspect, the disposition of the structural elements is such that the ferrite is placed in a manner to simulate the elements of a meshwork *with interrupted meshes* surrounding troostite-sorbite grains but partly isolated, an appearance more striking when examined at lower magification (Fig. 5).

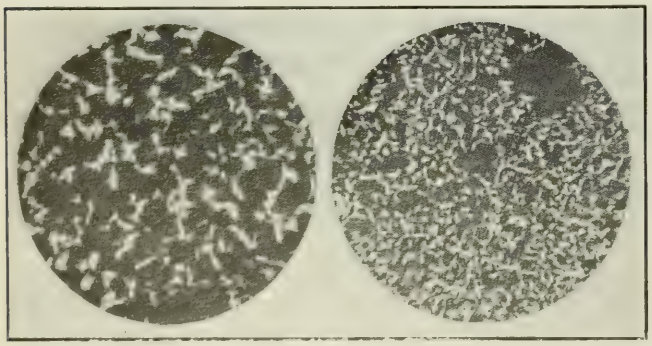

FIG. 4. Semblance of ferrite meshes in 62-point carbon steel; quenched from 710 deg. C. × 110

FIG. 5. Same steel as shown in Fig. 4, but at lower magnification. × 35

[4]That existing ferrite (or cementite) has a pronounced attraction for smaller quantities of nearby like material, even causing an apparent migration of 0.1 or 0.2 mm., is shown in my book on "The Cementation of Iron and Steel," when discussing the reasons for the presence of broad pearlitic zones in steels having a hypereutectoid case (Type II).

Further demonstration of the actuality of such "pseudo-meshwork" is unnecessary, considering the method of its birth—which has just been minutely analyzed—and the fact that the lighter areas are essentially and always have been separate granular crystallites. Furthermore, wide spaces always separate the elements of ferrite, which as a whole present extreme dissimilarity to cementite shells, which I admit are extruded to crystalline boundaries.

Continuing the passage through the transformation range will only cause ferrite grains to increase in size and develop their spinelike fringes, an inference confirmed by Fig. 6, quenched at 700 deg. C. A lower magnification (Fig. 7 at 70 diameters) shows the meshwork appearance to have progressed further, but to retain still its necessary genetic characteristics.

Confirmation by Reversing the Experiment

Entirely analogous results should be obtained by inverting the process, which can be handily done by quenching—after cooling to some definite temperature between Ar_3 and Ar_1—a partially cemented steel piece whose carbon content increases uniformly from about 0.30 to 0.80 per cent. This is evidently equivalent to fixing for examination in a single specimen a continuous variation in the time and temperature interval between beginning of ferrite deposition and its interruption.

The low-carbon edge of such a carburized steel is shown in 70-diameter microsection in Fig. 8. Originally it possessed

	Per Cent		Per Cent
C	0.19	S	0.03
Mn	0.52	P	0.03
Si	0.11		

and was cemented for 3 hr. at 1,000 deg. C. with CO and wood charcoal, allowed to cool slowly, reheated for 1 hr. at 900 deg. C. in a salt bath, cooled in the pot to 720 deg. C., quenched in water at room temperature, and finally tempered in a lead bath at approximately 575 deg.

Without repeating in detail the preceding discussion, it suffices to note that the structure as one proceeds from the high-carbon to the low-carbon regions develops all the characteristic facts established in what goes before. Low-carbon regions show wide markings of ferrite, resulting from an accumulation of roundish grains, while as the carbon increases, simultaneously appear more and

more suggestions of needle-forms as intersections of the plane of polishing with a plate or sheet of ferrite.)

That hypo-eutectoid steel slowly cooled through the transformation range contains an aggregation of disoriented crystalline granules of ferrite having forms resulting from the play of two different crystallizing tendencies is confirmed in almost daily observation by those working with such steels. One or two very definite instances may be cited.

Fig. 9 shows at 40 diameters the structure near the decarbonized edge of a 12-ton ingot of high-grade steel analyzing

	Per Cent		Per Cent
C	0.55	S	0.018
Mn	0.58	P	0.04
Si	0.26		

On account of a breakdown in the forge shop, the ingot remained in the heating furnace for four days at a temperature of about 1,150 deg. C., then was slowly cooled in ashes. Consequently, primary austenite was thoroughly well equallized in its carbon content during the long heating, and ferrite was allowed to segregate freely in the slow cooling.

Examination of the micrograph shows clearly in each ferrite crystal the morphological characteristics resulting from its habit and birth. Large masses of carbon-free material have formed near the decarburized region at the ingot surface. The sharp discontinuity at the inner surface of the carbon-free shell is but another exhibition of the strong tendency of insoluble material to collect about pre-existing masses of the same substance.

In later phases of segregation the individual crystallites have continued to place themselves side by side, constituting a chain-like ensemble imitating the threads of a mesh. The history of this ingot and the presence of large isolated ferrite masses preclude the separation of excess iron at austenite borders. The fact that no disturbing forces set up by slag inclusions were present in any of the steels experimented upon should, however, again be emphasized.

Another example of the separate morphology of β and α iron is shown in Fig. 10, at 65 diameters. This is from a 7-ton nickel-steel ingot for a gun-tube containing

	Per Cent		Per Cent
Ni	1.98	S	0.007
C	0.43	P	0.021
Mn	0.42	Si	0.22

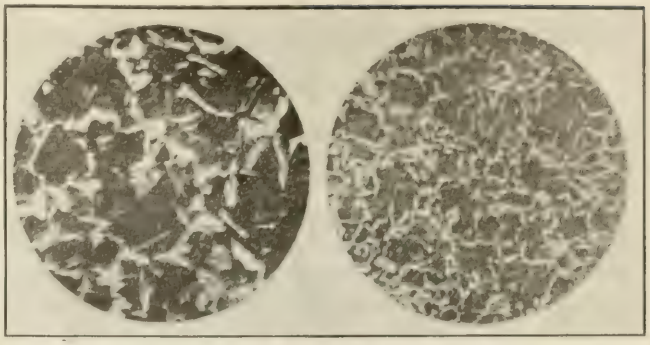

Fig. 6. Interrupted meshes in 62-point carbon steel; quenched from 700 deg. C. × 110

Fig. 7. Same steel as shown in Fig. 6, but at a lower magnification. × 45

which had been extremely carefully made and had undergone a heat treatment analogous to that just discussed. Further discussion of its obvious interpretation would be tiresome.

Conclusion

To summarize: The formation of the mesh-like structure in slowly cooled hypo-eutectoid steels is a fundamentally different phenomenon to that of the formation of the cementite shells in hypereutectoid steel, a conclusion in every way in accord with the well-known process of formation of non-homogeneous austenite from the molten metal. Whereas cementite actually segregates in sheets at the high-carbon interfaces between crystals of primary solidification, ferrite begins to separate in isolated masses in the central regions of austenite crystals at or near the points where the austenite began growing from the mother liquor, and where, subsequently, lacking the necessary heat treatment for perfect diffusion, the carbon must necessarily be lower than in its immediate surroundings. Only in the later progress of the segregation of insoluble ferrite do meshes appear resulting from the development of characteristic elongated fringes of α ferrite. This plate-like development of α iron is facilitated to an extent in direct proportion to the gradual disappearance of local variations in carbon concentration in the mother crystal. Thus long annealing gives a uniform diffusion and a more evident plate-like habit of α iron. Widmanstättian structure highly developed in coarse meshes is logically the end of the series as uniform austenite is reached.

Legal Notes

By Wellington Gustin

Law Regulating Contracts for an Approximate Amount Such as the Output for a Season

Does contracting the output of a plant or factory put the party under the legal obligation to operate the factory or plant under peril of breaching the contract for which he is liable in damage? What will the courts read into such a contract? What excuses may the party set up to relieve himself of responsibility? What is the meaning given to "season's output," "entire output," etc.? The answers to these problems may be found in the court decisions following:

Case of Kenan, McKay & Spier vs. Yorkville Cotton Oil Co.

In the latest case on the subject, Kenan, McKay & Spier, a Georgia corporation dealing in cotton linters, brought an action against the Yorkville Cotton Oil Co., a South Carolina corporation, in the Federal District Court, for breach of contract between the parties. By the contract the Cotton Oil Co. sold its "season's output of cotton linters, about 400 bales." It was said in the oil mill business the season began with August and closed with July, but it seems the period of active operations during which the most of the available seed is consumed covers only four or five months. It appears that the cotton oil company started up its mill in September and kept it running until the latter part of November, when it was closed down. In that time it turned out 155 bales of linters, all of which were delivered to the plaintiff dealer and paid for according to the terms of the contract. With the last shipment the cotton oil company wrote the dealers that owing to inability to borrow money for operating purposes it was forced to close down its mill for the season.

Upon objections to this action from the dealer the cotton oil company wrote the following: "We have shipped you our entire output, and, should we resume operations this season, we will ship you any further linters we make. We have nothing to add to this, and from our standpoint it closes the matter."

Following this letter the dealer brought suit in the state courts of South Carolina. Here a judgment against it was appealed to the Supreme Court of the state, and the judgment there affirmed. This court held that the cotton oil company was not bound to operate its mill in order to make the estimated quantity of linters, and that its obligation was discharged by the delivery to the dealer of all the linters actually produced. On the point the court said: "The buyer is bound to take the output, because he agreed to that. The seller is not bound to furnish more than the 'output,' because he has only agreed to furnish that much."

Losing on its point in the state court and there being a diversity of citizenship in the parties, the dealer brought the action in the Federal court. A judgment for the cotton oil company in the District Court was appealed to the Circuit Court of Appeals. (260 Fed., 29.)

This latter court said the complaint in this suit alleges bad faith, but there was nothing in the record to sustain it. Instead there was convincing and undisputed testimony that persistent efforts had been made by the cotton oil company to do business. The mill shut down solely for lack of money to keep it going. It appears that the company had little or no working capital, that its own borrowing power was exhausted, and that it had no assets with which to secure advances. It could not go on without ready money, and its inability to borrow was admitted. In this helpless condition it could not do otherwise than suspend operations, and hence it does not show lack of good faith in closing down the mill, said the court. Without showing lack of good faith on the defendant's part it cannot be said to have breached its contract.

Further the court said other facts seemed conclusive in themselves, in that the commercial products derived from the process of crushing cottonseed are oil, meal, hulls and linters, and the value of the last named product is barely 10 per cent of the whole. Hence it is not supposed that the defendant would go out of business in order to avoid the comparatively small loss on its contract with the dealer. Therefore the judgment of the District Court was affirmed.

Home Fertilizer & Cotton Oil Co. Case

The Supreme Court of Alabama was called upon to decide the point in a similar contract between plaintiff herein and the Home Fertilizer & Cotton Oil Co. (79 So., 367.) There the court said: "It is not possible to imply an obligation to make an article from an assumption of the limited obligation to sell, not a definite number of an article, but simply merely what the seller makes. . . . The seller having acted upon the buyer's promise to take his output, the buyer becomes bound to take what the seller has made, in reliance upon the buyer's promise, and the seller becomes likewise bound to deliver the output of his plant."

Case Between Plaintiffs and Dawson Cotton Oil Co.

In still another case, against the Dawson Cotton Oil Co. the latter was charged with shutting down its mill wrongfully and in bad faith for the purpose of evading its contract obligation. Of course, under such a condition there would be a breach of contract. However, the Court of Appeals of Georgia took occasion to say: "Of course, had the defendant discontinued the operation of his mill for some providential cause, or for any cause or causes not in any wise attributable to it, a delivery on the part of the mill of its output up to the time it ceased to operate would be all that the law would require."

Case of Brawley Against the United States

In the case of Brawley against the United States (96 U. S., 168) the U. S. Supreme Court said:

"Where a contract is made to sell or furnish certain goods identified by reference to independent circumstances, such as an entire lot deposited in a certain warehouse, or all that may be manufactured by the vendor in a certain establishment, or that may be shipped by his agent or correspondent in certain vessels, and the quantity is named with the qualifications 'about,' or 'more or less,' or words of like import, the contract applies to the specific lot; and the naming of the quantity is not regarded as in the nature of a warranty, but only as an estimate of the probable amount, in reference to which good faith is all that is required of the party making it."

Manufacture of Carbon Electrodes for Electric Furnace Purposes

A Description of the Raw Materials Used and Their Preparation, Calcining Furnaces and Plant Operation in the "Rammed Process" of Manufacturing Electrodes for Electric Furnace Purposes, With an Outline of Practical Deductions Obtained From Experimental Data

By WALTER L. MORRISON

CARBON electrodes for electric furnace work are divided into two classes: The graphite and the amorphous carbon electrodes. The amorphous carbon electrodes are again subdivided into two or more groups, depending on the process used in the manufacture. The method of manufacture covered in this paper is the so-called "rammed process" for the manufacture of electrodes.

The electrode is formed by ramming or pressing the material in a mold. The electrode after removal from the mold is allowed to cure, then is placed in a calcining oven and baked to remove the volatile matter. The raw materials used consist of carbonaceous products, and some form of binder such as tar and pitch.

Raw Materials

Pitch. The pitch used in the manufacture of amorphous carbon electrodes should be of the coal-tar variety, clean and of the highest quality. The pitch should contain at least 40 per cent fixed carbon, and the coke residue should be dense and tough. The so-called crude oil pitches and asphaltum pitches are not suitable for the manufacture of electrodes.

Coal-tar pitch is readily distinguished from the asphaltum pitch by odor or taste. A still better test is to volatilize a small portion of each in a crucible; the coal tar leaves a heavy, dense coke, while the asphalt leaves a very porous and friable coke, from which it is very hard to drive the last traces of volatile. Temperature during volatilization should not be too high; a good grade of coal-tar pitch loses nearly all its volatile matter at about 600 deg. F., while the asphaltum loses the last trace at a much higher temperature. The grade of coal-tar pitch used is that having a melting point from 150 to 200 deg. F.

The liquid tar used is also a coal-tar product. This material is the common unrefined product, having a fixed carbon residue of 25 to 35 per cent. This tar should be thoroughly dried before using to remove moisture. The coke residue is very similar to that of the solid coal-tar pitch, being dense and tough.

Coal. Anthracite coal is one of the best materials we have for the manufacture of amorphous carbon electrodes. This material is very dense and remains more or less so after calcination; especially is this the case with coals having a low volatile content.

The coal should be of the highest grade obtainable, high in fixed carbon, low in ash and as free as possible from other impurities. The fixed carbon should run 80 per cent or better and the ash should be under 5 per cent, preferably under 3 per cent. The writer has used coals running as high as 10 or 12 per cent with good results. When using inferior coals it is a good plan to mix some other suitable carbonaceous material of low ash content, such as petroleum carbon, or high-grade graphite, to lower the total ash content in the electrode.

Coke. The ordinary coke is not an essential material in the manufacture of large electrodes. Many attempts have been made to use the so-called petroleum or carbon residues from the manufacture of gas in which crude oil is used. Properly prepared petroleum coke works out very well in connection with anthracite coal.

The so-called petroleum carbon, which is very similar to lampblack, but having a higher volatile content, is extremely fine and porous. When a binder is mixed with this material, it absorbs such a large quantity to make a suitable mixture which will ram that on calcining the electrode will check. The electrode also has a tendency to spall when placed in service.

Foundry coke has been tried, but this material is so porous and of such high ash content that the conductivity is very low compared with other materials available.

Graphite. Graphite is an ideal material for the manufacture of electrodes, but unfortunately nearly all the natural graphite is so impure that it would have to go through a refining process, which would prohibit its use in an article which sells so cheaply as electrodes.

The artificial graphite is about the only solution of a graphitic material for electrode manufacture. However, experience has shown that the electrode made up from graphitic materials does not have as high an electrical conductivity as the amorphous carbon electrode which is subsequently graphitized, for example the Acheson electrode.

Much of the coal in the electric calcining process is converted into graphite, which adds greatly to the life and conductivity of the electrode. The graphite resists oxidation much more than the amorphous carbon.

Preparation of Raw Materials

Tar and Pitch. The tar and pitch are used in the molten state. The tar is heated in a large tank by means of a steam coil or steam jacket, to remove all traces of moisture and the lighter volatile oils. If this is not done but the tar added to the hot pitch without drying, it will cause the pitch to boil and perhaps take fire.

The ratio of tar to pitch depends a good deal upon conditions, the size of electrodes and equipment. Too large a quantity of tar should not be used, as the electrodes will not stand handling while warm in the green state. If all pitch be used, it makes the mixture too stiff to work properly or produce a uniform electrode. An all-pitch binder leaves the electrode extremely brittle while in the green state and is liable to break during the

cooling or curing. The temperature of the building has some influence upon the ratio of tar to pitch. During the winter months a higher ratio of tar should be used than during the summer months, unless the buildings are heated or are equipped with warming ovens or pits.

The fixed carbon or coke residue in the tar and pitch mixture should range between 30 and 40 per cent. The writer has obtained the best results with a mixture running 35 to 40 per cent fixed carbon. This is equivalent to one part tar to two or three parts pitch.

The tar and pitch are mixed in a large vat and kept molten by means of a steam coil. A measured quantity is then added to the ground carbon, which has been previously heated, and the whole mixed thoroughly.

Calcining Coal and Other Carbonaceous Materials. The purpose of calcining the raw materials is to lower the volatile content, thus preventing undue shrinkage, and check or mud cracks in the finished electrode.

There are several ways in which the calcination may be effected, viz., retorts, ovens, tubes and electric-resistance furnaces.

The main essential is to keep the material during calcination and subsequent cooling away from the air, as any oxidation raises the ash content. Also to carry the heat high enough to bring the volatile matter below 1 per cent, best results are obtained when the volatile is near 0.5 per cent or under.

The temperature necessary to carry out this operation is at least 1,300 deg. F., and preferably above 1,500 deg. F. The entire mass should be subjected to this temperature and results checked by pyrometers in the mass. Analyses should also be made from time to time in order to have the material under control and in the proper condition before going ahead with the process of manufacture. One of the best and most efficient methods of calcining is the use of the electric-resistance furnace.

Coal Calcining Furnace

There are two types of electric-resistance furnaces which are commercial, the vertical and the horizontal. The horizontal type is an intermittent furnace, being similar to the carborundum furnaces. The vertical resistance furnace is a shaft furnace and operates continuously. The coal is fed in at the top and after calcination removed from the bottom. The furnace is usually 20 to 40 ft. in height by 4 to 6 ft. in diameter. An iron shell of the proper dimensions is used. The upper part, in which the calcination takes place, is lined, while the lower part is unlined, to allow the cooling of the calcined mass before removal from the furnace, to prevent undue oxidation.

The current or kw. input into the furnace is regulated by drawing calcined coal from the bottom of the furnace, when the current becomes too high. This allows green coal to move down, thus increasing the resistance of the mass between the two electrode terminals.

Green anthracite coal has a very high electrical resistance, but as the volatile matter is removed the resistance drops very rapidly. The furnace works very satisfactorily, and with slight variation of current. The power consumed per ton of coal varies from 360 to 750 kw.-hr. depending on size of the installation and the amount of graphite produced.

There are two types of shaft resistance furnaces which can be used. One has two rings of carbon insulated from the shell and acting as electrodes to carry the current. The electrodes are spaced from 2½ to 5 ft. apart, depending on the voltage used. When operating with this type of furnace it is of advantage to have a transformer with several different taps to vary the voltage. The most desirable voltages would be 409, 609, 809, 1,009, the lower voltages being used for regular operation. The furnace has to be started with a good conducting carbon material. The upper part of the furnace is lined with a non-conducting material, with the exception of the carbon rings.

The other type of shaft furnace has an upper and lower central electrode. The lower electrode is fixed, the clamp and terminals being protected from the descending hot materials.

The upper electrode is movable and therefore allows a wider range of regulation, particularly when there is only one voltage available.

The calcination of coal requires a heavy current and low voltage. In normal operation the voltage should not exceed 60 volts, except in very large furnaces, to obtain the best results. The current density in the shaft between the two electrodes should be 5 to 10 amp. per sq.in. sectional area of shaft. This type of furnace has been developed to use with fine coal, the so-called slack, which is obtainable at a very low figure. This furnace will not work as satisfactorily on the lump coal as the furnace with the ring electrodes, on account of the more or less restricted openings in the shaft due to the central electrodes, which cause hanging in the shaft and irregular working conditions.

If fine slack or coal is used with the ring electrode furnace, the electric current has a tendency to pass so close to the lining as to cause a gradual reduction and deterioration of the lining by the excessive heat. This condition necessitates very frequent repairs, besides giving a poorer quality of coal when conditions get very bad. If the current be forced through the center of the mass, the excessive heating in the middle of the coal does no harm but is really of benefit, as it promotes the formation of large quantities of artificial graphite.

The calcining furnace during operation should be under laboratory control, frequent analyses being taken, to determine the status of the operation and detect any irregular working of the furnace. The best practice is to take at least one sample from each shift. A recording ammeter is also very useful to check up the furnace operation.

Construction of Molds and Dies

The design and construction of molds depends upon the process used in the manufacture. In the making of plain rammed electrodes which are not subjected to pressure other than the ramming, a split mold is used, which is constructed of light casting or heavy boiler plate reinforced with angles and held together with bolts. After the mold is rammed, the bolts are loosened and the electrode is removed. The electrodes made in this manner are those of special shapes: the square, hexagonal, etc., which are used without nipples for joining together. They vary in length from 6 to 9 ft. The electrodes which are not subjected to pressure after ramming are not nearly as good as the others. The split mold is not strong enough mechanically to withstand much pressure, such as is given the electrodes made in the one-piece mold.

The solid mold is of heavy construction and slightly with a binder, consisting of pitch and tar. The amount of taper from $\frac{1}{16}$ to $\frac{1}{32}$ in. per ft. on the diameter of the mold. The thickness of the walls is more or less an arbitary matter, since the material being subjected

to pressure does not act as a liquid nor as a solid. Furthermore, if the mold was designed to resist the pressure of a fluid and figuring on the pressures which are used, it would mean the use of an extremely heavy casting, which would be troublesome to handle. We usually figure from one-fifth to one-third the thickness required for a fluid, allowing a good factor of safety. The mold is made from 12 to 20 in. longer than the finished electrode desired.

The dies forming the female thread on the ends of the electrodes have a very low pitch and shallow thread. The diameter of the thread or nipple is approximately half the diameter of the electrode with which it is to be used. The pitch on the 18- to 24-in. diameter electrodes runs about one thread in 2 in., depth of thread $\frac{3}{4}$ to 1 in. There should be ample clearance for the nipple in the female thread, at least $\frac{3}{16}$ in., to allow for any blistering or slight imperfections which may occur either on the nipple or in the female thread during baking. The nipple can be made up in a heavy cast split mold which has been properly machined.

The dies forming the female threads in the ends of the electrode, after the mold comes from the press, are removed by screwing them out.

Calcining Furnaces for Electrodes

The large electrodes are so heavy and of such length that it is necessary to bake them on end. This requires the use of saggers, iron tubes, or a specially constructed furnace with chambers constructed very much like a large vertical muffle. The furnace should be so constructed as to obtain a uniform temperature throughout the entire length of the electrode. Pyrometer openings should be placed in several parts of the furnace, as well as in the retorts, to have proper control of the furnace.

Gas, oil or powdered coal may be used for firing the calcining furnace. The retorts or chambers should be large enough to allow at least 2 in. of packing material on all sides of the electrode.

Mixing

The calcined raw materials are ground so as to form a compact mass. This is best done in a dry pan, the material all passing through a screen. After grinding and sizing, the different sizes are warmed and mixed with a binder, consisting of pitch and tar. The amount of binder added varies from 15 to 20 per cent, depending on the kind and grade of materials used. There should be just enough binder to make the material adhere when molded into a ball with the hands. It is advisable to treat the mixture in a hot wet pan, to work out the air and get the tar completely worked around the particles of coal and petroleum coke. The mulling operation should require from 12 to 20 min., in order to make the toughest and most compact mass. If during the mulling the mass should become too dry, then more tar should be added. After some experience this is readily told by inspection. Too much tar should be avoided, as it causes undue shrinkage of the electrode and causes an excess pressure to be exerted on the electrode mold during squeezing, because the material has a greater tendency to flow under pressure and approaches the property of a fluid.

The pan should be sufficiently hot to keep the mass in a plastic condition; otherwise, when ramming, cavities are apt to exist in the electrode, also there is an imperfect bond between batches. The pan and rolls may be kept warm by means of a small gas or oil flame, and in no case should the pan or rolls be hot enough to volatilize the tar. The tar begins to boil or volatilize at about 500 deg. F. In making up the mixture for the nipples it is necessary to add a somewhat larger amount of tar, in order to produce a perfect thread. This is more or less a matter of experiment to determine the exact amount necessary, as conditions vary from time to time. After mixing thoroughly the material is placed in a mold for ramming.

Ramming

For the purpose of ramming, a bar or rod with an iron shoe secured to the end works up and down in the mold, the action being very similar to that of a stamp in a stamp mill. On the downward stroke you get the full weight of the stem and shoe. In designing this type of ram one must take into consideration the fact that the mold is constantly filling up. This calls for a special design other than the ordinary ram.

In order to maintain a constant height of drop as the mold fills up, a rack is placed on the stem and a pinion gear engages the rack, the pinion gear having several teeth omitted to allow the drop of the stem. Thus the height of drop will always be the same and can be varied by changing the size of pinion.

Another very simple ram is one having a round shaft with a shoe on the end and passing through two guides, a cable being secured to the other end. The ram is operated by a long-stroke double-acting steam cylinder, the slack and adjustment being taken care of by a small winch.

The shoe is specially constructed, having a tapered top to allow for passage of material and to be kept clear. The size and shape of shoe depend upon the electrode to be made. There should be a clearance of 1 to 2 in. between the ram and the sides of the electrode mold, for the passage of the carbon and pitch.

The mold is first warmed, then the inside surface oiled, the lower die placed in position, and the mold placed under the ram.

Material to a depth of 8 or 10 in. is placed in the bottom of the mold, then the ram is started. One man shovels in the mix while the ram is working. The shoes on the bottom of the ram have large conical points to prevent the formation of a joint in the electrode mass. After the mold has been rammed full, if the electrode is to be pressed, the mold is placed on a car, the upper die is placed in position, and the car is then moved to the press.

Pressing

The bottom plate of the electrode mold has an opening large enough for the passage of a die fastened to the plunger of the press. The electrode is subjected to pressure in three steps:

First, pressure is exerted on the bottom of the electrode, with the top of the mold resting against the top or upper platen of the press. This initial pressure is to allow sufficient space at the bottom of the mold for the removal of the electrode, or rather freeing from the sides of the mold in the last operation.

Second, an iron bushing of smaller diameter than the electrode is placed on the upper die, bearing on the upper platen when pressure is resumed. This exerts pressure on the top of the electrode as well as the bottom. During this second operation pressure is exerted on both ends to a maximum for the operation, and varies from 100 tons for an 8- or 10-in. diameter electrode up to 500 tons for 20- or 24-in. diameter electrode. These

represent the total pressure on the full cross-section of the electrode.

Third, pressure is exerted on the top of the electrode only, the mold resting on a plate. This loosens the electrode in the mold, as the mold is slightly tapered for this purpose. The pressure for this operation should not exceed that used in the second operation. If it should, the electrode must be sticking in the mold, due either to the use of too much tar or a careless oiling of the interior of the mold, or starting with the mold too hot, or a combination of these causes. The electrode should be of such composition that a hard, tough skin exists on the outside. When the electrode has become loosened, the mold is removed from the press, picked up by the crane and lowered into the pit. The bottom plate is removed, and the mold skinned off the electrode by hoisting the mold. In a short time the electrode is firm enough to withstand handling, is taken to the calcining oven, and packed for calcining.

Calcining

The electrodes are placed on end and packed in carbonaceous material, which is more or less porous to allow passage of the volatile gases from the electrodes. The material should be placed firmly around the electrodes, and they should also be covered to some depth.

The firing should proceed slowly, and after attaining a temperature of 600 deg. F. the furnace should be held at this temperature from two to four days depending on the size of the electrodes. This allows for the removal of the greater portion of the tar, which comes off slowly at this point, without injuring the conductivity of the electrode. The temperature may then be raised gradually up to 1,300 or 1,400 deg. F. and held at the upper limit till the coolest point of the furnace has reached 1,300 deg. The firing period requires usually from seven to ten days. The furnace is then cooled down, taking four to six days, making the total period of calcination fourteen to sixteen days.

If the temperature is raised too rapidly and before the volatile is removed from the electrode, the violent volatilization of the tar often causes fractures and splits, and very often a honeycomb structure which impairs the electric conductivity.

Surface checks on the electrodes are caused by poor mixing, high volatile content in raw materials or improper calcining. A few surface checks as a rule do not impair the electrical properties of the electrode.

Experimental Data

Electrodes having a high volatile content are not serviceable for electric-furnace work. The lower the volatile matter in the finished electrode, the better the performance in the furnace.

Electrodes were made from the so-called gas-house carbon, but these were found to be very unsatisfactory. In the first place, the carbon is so extremely fine it is like a sponge and absorbs large quantities of pitch before it is workable. After the molding operation it is very difficult to remove the electrode from the mold, as it has little mechanical strength and will hardly support its own weight. During the baking of the electrode the shrinkage was so bad as to cause large transverse cracks. The volatile in the finished electrode was also very high. The last of the volatile is very hard to remove and this is a property peculiar to all products derived from petroleum.

It has been suggested to make briquets of the gas carbon, using a pitch binder, and burn these at a very high temperature to form solid pieces of material as a base, which is subsequently crushed and sized and forms a basis for electrode material. This works out fairly well, but is very expensive, and makes the cost of the finished electrode much higher than when using other materials which have a better structure. The only reason for using the gas-house carbon is on account of its purity and its low ash content. For certain electrochemical work where a very pure electrode is required, it may find a use, but for ordinary smelting operations it is out of the question, on account of the cost of handling this material.

In preparing the coal for electrode manufacture, many different methods of calcination were tried and we finally resorted to the electric calcining furnace, which gave us a calcined coal running under 0.5 per cent volatile.

The first calcining operations of the electrodes were carried out by packing the electrodes in a horizontal position on a large hearth, using crushed coke, and covering the coke with mud to prevent oxidation. Several of the electrodes were lost due to transverse cracks and in some cases were completely severed during calcination.

The next batch of 10-in. electrodes was packed in 14-in. iron tubes and stood on end in the furnaces. All the electrodes came out without any breakage losses.

A furnace was then constructed with six chambers 25 in. x 56 in. x 10 ft. deep, using firebrick construction. These chambers were designed to hold 17-in. diameter electrodes x 8 ft. long.

Firing is done along the sides of the chambers, and works out very satisfactorily. Particular attention must be paid to the firing, and the success of this final operation depends upon the first four days' firing. During this period the temperature of the electrode chamber should not exceed 650 deg. F.

The shrinkage of electrodes during calcination is not very great in the case of rammed electrodes, and varies to a more or less extent, depending on conditions, as to mix used, total pressure used in ramming, and calcining. However, this is not such a vital point in the manufacture as the electrical conductivity, behavior when subjected to sudden changes of temperature and resistance to oxidation during service.

Many protective coatings have been tried to prolong the life of the electrode in service, but the writer has not found or heard of anything which works out very satisfactorily in furnace operation.

Portland, Ore.

British Output of Iron and Steel in 1919

The National Federation of Iron and Steel Manufacturers has issued the following return of the output of pig iron and steel in the United Kingdom during 1919. The figures are based upon returns, collected by the Federation, which, for the month of December, cover 93 per cent of the output in the case of pig iron and 96 per cent in the case of steel ingots.

Months	Pig Iron Tons	Steel Ingots Tons	Months	Pig Iron Tons	Steel Ingots Tons
January	664,000	718 000	September	574 000	718,000
February	625,000	734 000	October	445 000	438,000
March	684 000	758 000	November	630,000	693,000
April	653 000	668 000	December (approximate)	640,000	680,000
May	662,000	755 000			
June	612,000	631,000			
July	660 000	618 000	Total, 1919	7,370,000	7,885,000
August	521,000	474,000	1913	10,260,000	7,664,000
			1918	9,072,000	9,591,000

Technical Application of Hydrogen in Hydrogenation or Hardening of Oils

Principles Involved in Saturating Unsaturated Oils by Hydrogenation — Commercial Adaptability of the Method to Industrial and Edible Oils—Technology of the Process and a Schematic Outline of the Apparatus Used

By HARRY L. BARNITZ
Consulting and Construction Engineer

A VERY extensive use of hydrogen has developed in connection with the fat industry. By the introduction of hydrogen into fatty bodies and oils of low melting point these are converted into hard fats of higher melting point. In other words, oils which are composed of unsaturated acids, such as oleic acid and their esters, will combine with hydrogen in the presence of a suitable catalytic agent, forming a saturated compound

$$C_{17}H_{33}COOH + H_2 \rightarrow C_{17}H_{35}COOH$$
oleic acid + hydrogen → stearic acid

Fatty vegetable and animal oils may be described as consisting of a glycerine part and an acid part. The composition of the glycerine part is constant. The composition of the acid part varies from oil to oil, and is characteristic of any one oil, or of any one group of oils.

Several important vegetable and animal oils contain an acid part having the general chemical formula $C_nH_{n_2}O_2$. Among these we have cocoanut oil, palm oil, palm kernel oil, butter fat, lard, tallow, and various "butters" such as cocoa and mace butters. These oils and fats are characterized by the possession of a thick consistency; that is to say, they have high melting points, or, generally speaking, they are naturally "hard."

A considerable number of important vegetable and animal oils differ from those just discussed, in that their acid parts fail to correspond with the general formula stated, to the extent of two, four, six or eight atoms of hydrogen. For instance, in rape oil, and certain fish oils, two atoms are missing. Four are absent in the acid parts of cottonseed oil and soya bean oil. In linseed oil six atoms are missing, and as many as eight atoms are lacking in certain liver and blubber oils. These oils are characterized by the possession of a liquid consistency.

Saturating Unsaturated Oils

The acid parts of these oils are termed "unsaturated," for they are capable of picking up and combining with additional atoms of hydrogen. Under normal conditions, hydrogen, even in the nascent state, is quite without action on the fatty oils. To convert an unsaturated oil into a saturated oil has led to much investigation and it has been found that the addition of the hydrogen atoms can be effected if the oil is suitably treated with hydrogen in the presence of finely divided nickel, platinum or palladium. Each of these metals acts as a catalyst, and is left unaltered after the hydrogen has been taken up by the oil.

For the purpose of industry the world's supply of solid fats is deficient, while the supply of liquid oils is superabundant. Solid fats of vegetable origin are especially scarce. The hydrogenation process permits us to make good the deficiency by converting some of the superabundant liquid oils into hard fats.

Hydrogen has another advantage which is in some cases even more important than solidification effect. The saturation by hydrogen of the unsaturated bodies renders the oil much less likely to oxidize and rancidify.

Commercial Applicability of Hydrogenation Process to the Soap Industry

As an instance of the commercial applicability of the hydrogenation process, we may look for a moment at the soap-making industry. Tallow may be said to be the ideal substance for the soap manufacturer to work with, giving the necessary stiffness and texture to soap and yielding a firm soap such as we use daily.

Tallow, however, is expensive, and is obtainable only in limited amounts. Accordingly the soap manufacturer falls back upon some of the harder oils, such as palm oil, palm kernel oil and cocoanut oil. These oils are also expensive and are in increasing demand in other industries. If, on the other hand, the soap manufacturer tries to replace them with one or the other abundant naturally liquid oils, such as soya bean oil or whale oil, his product loses greatly in quality, and is apt to be a soft, sticky mass, unsuitable or unsalable as soap for many purposes. Hardening these oils before using them, he obtains a substance practically identical with tallow without affecting the yield from them of that valuable byproduct of the soap-making industry, glycerine. Therefore the hydrogenation process places at the disposal of the soap manufacturer a wide range of oils which otherwise would be next to useless for his purpose.

These remarks will also apply to the candle-making industry, which also calls largely for fats rather than oils.

Edible Synthetically Hardened Oils

Fats are now in demand for margarine and certain other edible compounds to a greater extent than can be conveniently met from natural sources of supply. It is certain that synthetically hardened oils will soon be extensively used for edible purposes throughout the world.

Great quantities of cottonseed oil at present are hardened. Increasing quantities of fish and whale oil, linseed, soya bean, cocoanut, palm kernel, palm and other vegetable oils are also being subjected to the process.

A word of explanation is no doubt desirable with regard to the hardening of cocoanut oil. This oil is just on the border line between liquid and solid fats, chang-

Copyrighted, 1920, by Harry L. Barnitz.

ing from a liquid to a solid state with fluctuations in temperature. All its acid part is not saturated, but contains portions of unsaturated acids. It is therefore capable of absorbing a certain amount of hydrogen, and so becoming harder than normally in this climate, but its melting point is not sufficiently raised to meet the requirement of a butter substitute which will stand summer temperature or the high temperature of countries in the torrid zone. To raise the melting point of the hydrogenated cocoanut oil to that required in lard or butter substitutes a small amount of hardened peanut or cottonseed oil is added, therefore contrary to widespread supposition cocoanut oil is not capable of being hardened by hydrogen to any great degree; in no sense comparable with hardening of such oils as cottonseed, soya bean, peanut and oils of this character. Cocoanut oil is almost saturated, as shown by having an iodine number of less than 10, while, for example, that of cottonseed oil is over 100. The iodine number is commonly used to express the extent to which hydrogen has been taken up by the oil in hydrogenation operations.

Characteristics of Hardened Oils

The characteristics of these hardened oils are white, tasteless, odorless substances of tallow-like consistency. They should all be identical, whatever may be the particular oil started with, and in theory and practice such identity seems to be attained, at least in the oils as freshly hardened.

It is customary to harden the oils at the soap works, or wherever else they are to be used or are otherwise employed, with but little interval between being hardened and being treated in industrial processes. The point of importance, therefore, is that certain oils will be hardened before shipment to this country. In the Orient and tropics the process is attracting considerable attention from the cocoanut and soya bean oil producers, the idea being that hardened oils may be shipped and carried without risking loss through leakage, which is a serious item in the shipment of liquid oils for long distances.

The technology of the process is dependent primarily upon two conditions—first, the careful preparation of the catalyst, and, second, the use of very pure hydrogen. A slight variation of procedure may quite readily result in an entire failure to harden the oil.

The catalyst ordinarily used on a commercial scale is metallic nickel prepared in a finely divided state by chemical precipitation. Once made, it must be kept strictly apart from certain other substances, notably air, moisture, sulphur, phosphorus, arsenic, carbon monoxide, chlorine, etc. These substances oxidize or otherwise react on the metallic nickel, and destroy its catalytic action, 0.1 per cent of H_2S being sufficient to destroy the catalytic action of nickel. Certain kinds of fish oils contain sulphur, and if this is not removed before attempting to harden these oils, the sulphur will quickly destroy the activity of the catalyzer. The action of these substances on the catalyst is exercised in three ways. First, it means that the hydrogen used must be very pure and free from moisture and sulphur compounds. Second, the oil to be hardened must be thoroughly free from moisture, which it usually contains when received. Third, in preparing the catalyst a stage is reached when it must be treated and handled out of contact with the atmosphere.

Technology of the Hydrogenation Process

When all the necessary conditions are complied with, the process is not difficult. The oil with the catalyst (usually the nickel catalyzer is employed in the proportion of 40 to 60 lb. per ton of oil) added is heated in an atmosphere of hydrogen inside a closed vessel termed the "converter." The oil and hydrogen are brought into intimate contact and at the end of 2½ to 4 hr. the absorption is found to be complete. The temperature at which the work is carried on is of great importance. For any given pressure of hydrogen inside the converter there is a definite temperature which must be reached before the absorption begins. At atmospheric pressure this temperature appears to be about 250 deg. C. In practice such a temperature would almost certainly result in the hardened oil being discolored. To avoid this, some temperature approximating 200 deg. must be used. The

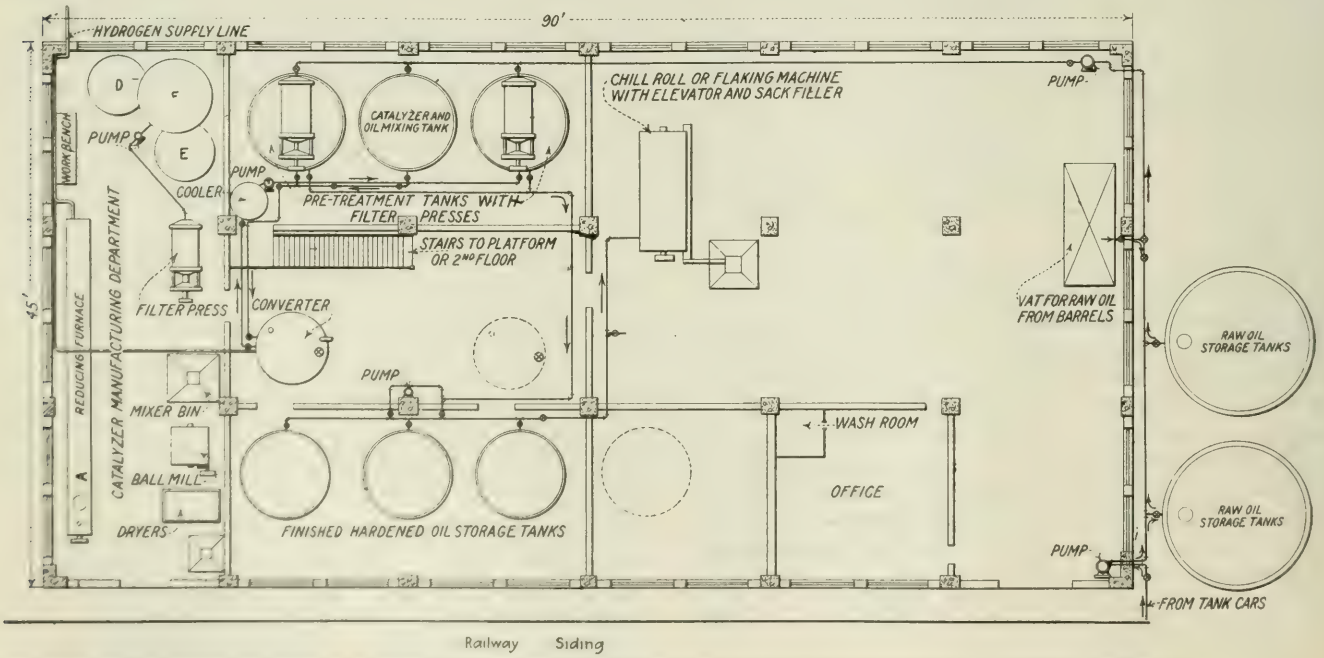

FIG. 1. DIAGRAMMATIC PLAN OF A 1,000 LB. PER HR. OIL-HARDENING PLANT

pressure of the hydrogen has to be increased above atmospheric as the temperature is decreased. A normal working condition is a temperature of 170 to 180 deg. C. in conjunction with a pressure of 70 to 80 lb. per sq.in. When the absorption is complete, the oil is run out of the converter, cooled, filtered, and allowed to solidify. A general diagrammatic plan of a modern oil-hardening plant of a working capacity for the treatment of 1,000 lb. of oil per hr., with provision for doubling the output, is seen in Fig. 1. The steam boiler and condenser for distilling the water is placed in the basement and is not shown in the plan.

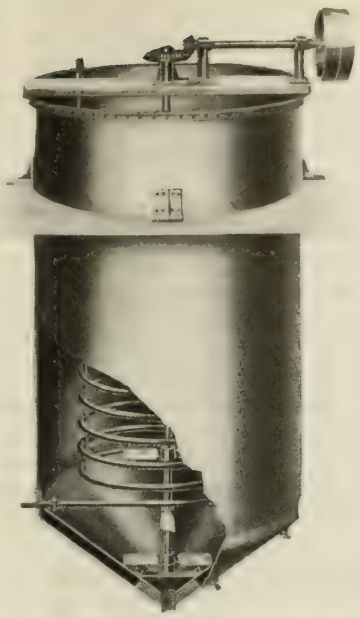

FIG. 2. PRE-TREATMENT TANK

Preparation of the Raw Oil

The characteristic of the raw oil to be treated may be thick, for instance, as cocoanut oil, therefore necessary means has to be provided for heating the oil before it is emptied into the storage tanks from the barrels and tank cars when received at the works and the oil in the storage tanks must be kept sufficiently liquid to be pumped on to the next stage.

The means provided for reducing and maintaining the oil in the liquid state consists of steam jets for heating the barrels—the tank cars usually have steam coils permanently installed with threaded connections to attach to the source of the steam supply at the works, the storage tanks have flat steam coils at the bottom. The oil in the barrels is first emptied into a vat and from this vat pumped into the storage tanks. From the tank car the oil is pumped directly into storage tanks.

Dessication of the Raw Oil

As the catalyst should not be brought into contact with moisture, it is necessary to extract the moisture from the oil by dessication. This is accomplished in the two pre-treatment tanks. First the oil is pumped from the storage tanks into the open circular pre-treatment tanks, Fig. 2, having conical bases and fitted with mechanical agitating gear and with steam-heating coils. The oil in them is freed from the moisture. The outlet for the oil is through a valve at the conical base. Steam, fluid level gages, and thermometers are fitted in connection with the pre-treatment tanks. The oil leaving the pre-treatment tanks is mixed with the catalyzer in the mixing tanks and is now ready to be brought into contact with the hydrogen in the converter.

Method of Preparing the Catalyst

There are several methods of preparation of the catalyzer, but the one to be described herein has perhaps been one of the most widely used. In general the catalyst employed is finely divided metallic nickel. It is received at the hardening plant in the form of nickel sulphate in crystals. Its preparation consists of making a solution of the nickel sulphate in tank *D* and another solution of sodium carbonate in tank *E*. Each of these tanks is fitted with an open steam jet to facilitate the preparation of the solution. They are erected over a third tank *F* provided with means for mixing the two solutions when they are turned into it. The result of this mixture is the precipitation of insoluble nickel carbonate and the passage of sodium sulphate into solution. Previous to the admission of the two solutions a quantity of finely divided refractory neutral material is placed in the mixing tank. In practice this material is usually kieselguhr. Its employment is to act as a carrier for the nickel. The mother liquor, the precipitate of nickel carbonate, and the kieselguhr are drawn off from the mixing tank and pumped through a filter press. When the filtering is completed the nickel carbonate and the kieselguhr are found consolidated on the filter cloths as cakes. These cakes are thoroughly dried in hot air driers, and then reduced to powder by means of a ball mill. The carbonate now has to be roasted or calcined in a furnace so as to reduce it to the form of oxide.

The next procedure is the very delicate operation of reducing the oxide to the metallic form. This is effected in a reduction furnace by heating at a certain temperature the oxide in contact with hydrogen, which must be entirely free from air. The furnace employed is either gas-, oil- or electrically-heated and varies in the internal mechanism. Fig. 3 is a diagrammatic sketch of one of the later improved types which is electrically heated

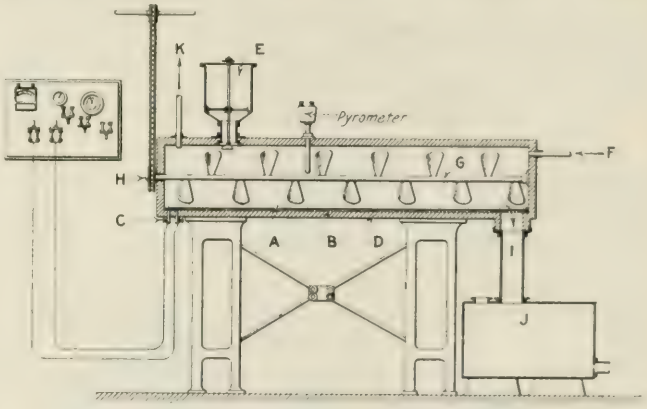

FIG. 3. DIAGRAMMATIC SKETCH OF CATALYZER FURNACE

and automatically controlled. The furnace *A* is cylindrical in form, and is closed at both ends. It is heated through the under surface at *B* by electrical connections at *C* and incased in heat-insulated material *D*. The pulverized material is fed automatically at the top *E* and the hydrogen is admitted at the end *F* and after circulating through the furnace passes through outlet *K*. Inside the cylinder there is provided a reciprocating worm *G* which is kept revolving slowly by means of the chain drive pulley *H*. The movement of the worm constantly exposes fresh portions of the material to the action of the hydrogen, and also determines the rate of flow at which the material falls through the furnace at *I*. The substance fed to the furnace in the form of the carbonate is calcined to the oxide. After leaving the furnace the reduced material mixed with the kieselguhr must not be permitted to come into contact with the air. It is therefore caused to fall into a tank of oil

J of the same kind and quality as that to be hardened. This black, oily mixture is ground to a suitable consistency, and is added, with the oil, in the converter.

In the early days the experimenter had considerable trouble with the hydrogenating process. He formed erroneous conclusions, particularly regarding the construction and mechanism of the converter. For this reason there is found a great diversity in its construction.

The secret of oil hardening depends primarily on the activity and uniformity of the catalyzer. Therefore with a highly refined oil and a catalyzer with the properties just stated the oil may be hardened in most any form of converter.

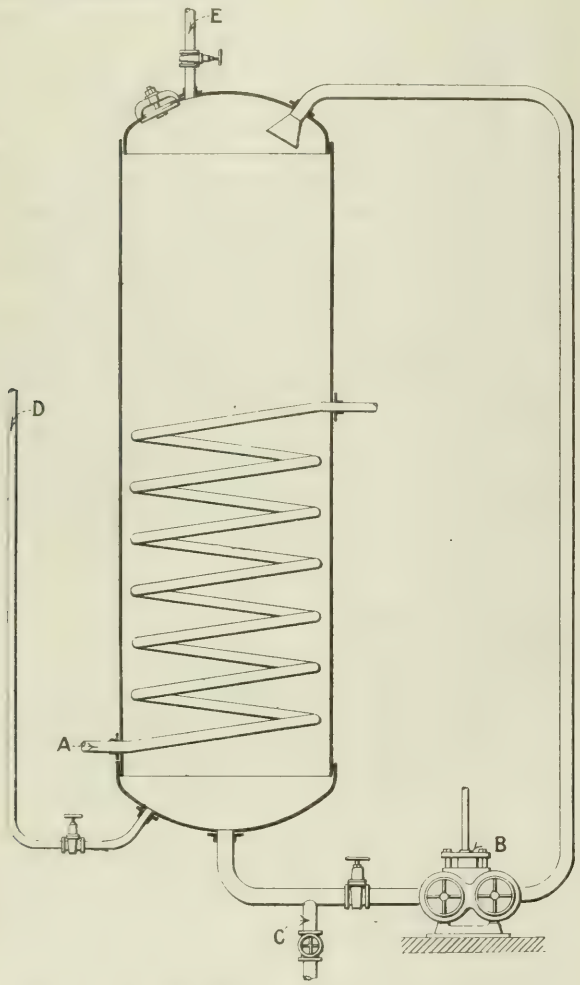

FIG. 4. DIAGRAMMATIC SKETCH OF CONVERTER

The converter as shown in Fig. 4 is a cylindrical upright tank, closed top and bottom. The lower half is occupied by steam coils; also, during operation, by the oil be be treated, mixed with the catalyzer.

A pump *B* draws the oil from the foot of the converter and discharges it continuously through a spray onto the oil in the lower half of the converter.

When conditions are properly regulated, the pressure inside the converter, as the hydrogen is pumped in, is seen to rise at first. On reaching a certain point, depending upon the temperature maintained in the oil, the pressure becomes stationary, indicating that the hydrogen is being absorbed by the oil as fast as it is pumped in. By sampling, the degree of hardness is determined, the oil is drawn from the converter through the pipe *C*, is cooled and filtered. The cooling is not sufficient to solidify the oil, but is only sufficient to prevent the oil from injuring the cloths of the filter press. Practically the whole of the metallic nickel and the kieselguhr is held back in the filters. The pressed cakes of catalyzer left on the cloth are washed and freed from oil, are broken up, and are returned to the catalyst-preparing department, where the material is ready for further use. With a well-refined oil the catalyzer may be used over and over again, for days or weeks. As there are some losses in handling the catalyzer, it is customary to make up for the loss by the addition from day to day of a small amount of fresh catalyzer.

Hydrogen Required

The amount of hydrogen required in the hardening of oils varies from 500 to 5,000 cu.ft. per ton of oil, depending upon the nature of the oil, the degree of saturation of the oil and extent of hardening required.

The amount of hydrogen consumption from actual experience on some oils is as follows:

	Cu.ft. per Lb.
Cocoanut oil	0.25 to 0.40
Soya bean, corn, peanut, cottonseed	1.75 to 2.0
Fish oils (menhaden oil)	2.0 to 2.5

The amount of hydrogen as given includes that used in making the catalyzer which would be used in the hardening of the particular oil in question.

COST OF HARDENING ONE TON OF FISH OIL (MENHADEN)

Hydrogen, 4,600 cu.ft. @ $1.15 per 1,000	$5.17½
Loss of catalyst (nickel sulphate @ $11.25 per cwt.; kieselguhr @ $4.12 per cwt.; carbonate of soda @ $13.34 per ton)	3.75
Electric current for heating @ $0.03 per kw.-hr.	.30
Power	.25
Steam, 1,375 lb. @ $0.85 per ton	.58
Water, 450 cu.ft. @ $0.20 per 1,000	.09
Filter cloths, 1 yd. @ $0.35 per yd.	.35
Labor (including preparation of catalyst):	
1 Foreman @ $0.90 per hr	
2 Laborers @ $0.40 per hr	1.70
Running repairs	.49
Total	$12.68½

The cost of hydrogen depends upon the manner obtained—for instance, hydrogen can be generated at the hardening plant, it can be purchased in cylinders and can frequently be obtained as a byproduct. In the latter event the price is very low, considerably less than in the above estimate.

It will be noted in the above estimate that this particular fish oil requires more hydrogen to harden it than vegetable oils or most any other oil excepting some certain fish, liver, and blubber oils.

The character of the generating apparatus for the production of hydrogen in relation to the hydrogenation of oils is one of utmost importance, as many factors enter into its proper selection.

The purity of hydrogen is one of importance, but there are factors that are equally as important in other ways to consider. These are:

First. Which particular type of equipment is best adapted to local operating conditions.

Second. Of the various types of the same systems of production, which types are efficient, safe, simple, most economical and conserve long life in operation.

Considerable hydrogen-generating equipment has been installed which has not proved satisfactory due to one or all of the above factors. The selection of such equipment should be left to those who are qualified by technical knowledge and long experience in the field of hydrogen-generating apparatus.

New York City.

The Lake Asphalt Industry*

Nature and Origin of Asphalt—Description of Most Important Sources of Natural Asphalt: Trinidad Lake and Bermudez Lake—Refining and Fluxing—Ultra-Microscope Shows Presence of Colloidal Clay Particles—Review of Theory of Colloidal State

By J. STROTHER MILLER, Jr.†

ASPHALT as obtained in nature and requiring very little if any refining to make it suitable for use has been of general interest for a great many years for many different purposes. In more recent years there has appeared another class of so-called asphalt produced in the oil industry when certain types of crude asphaltic oils are distilled. There being two general sources, namely, natural solid and artificial, or oil, asphalts, the question is immediately brought up, How was the natural product formed and what definition can we give of asphalt which would indicate these two general classes?

Theory as to Origin of Asphalt

Much work has been done upon that type of natural solid asphalt obtained from Trinidad Pitch Lake, in the Island of Trinidad, and I would refer you therefore to a report by Clifford Richardson upon this general subject of origin, appearing originally in the *Journal* of the Society of Chemical Industry for January, 1898. Briefly summarized, the theory there outlined is that asphalt is in the process of formation today. It does not originate as such, but is a secondary product, resulting from the transformation of suitable lighter form of bitumen, malthas, or even thinner oils, into harder bitumen by condensation and polymerization, a reaction in which sulphur and probably sulphates seem to take an important part. No high temperatures seem necessary once the change is initiated, but time is necessary.

Manufacture of Oil Asphalt

The method of manufacturing an oil asphalt is probably familiar to you all. As asphaltic oil is distilled, the gasoline naphthas, burning oils, gas oils and lubricating oils are obtained from the distillate, and the residue is controlled to give the best grade of oil asphalt obtainable from the particular crude oil under manipulation without economically sacrificing any of the more valuable distillates.

Asphalt Defined

There have been several definitions proposed for asphalt. I will cite two or three.

First. Asphalt may be simply defined as a solid or semi-solid form of mineral bitumen, either pure or containing more or less mineral or other earthy matter. Speaking in general terms, it may be said there are three grand divisions of natural mineral bitumens, viz., gaseous, liquid and solid. The asphalts consist of a mixture of various saturated and unsaturated solid hydrocarbons and their derivatives.

Second. Asphalt, solid or semi-solid native bitumens, consisting of a mixture of hydrocarbons of complex structure, largely cyclic and bridge compounds, together with a small proportion of their sulphur and nitrogen derivatives, but free from any appreciable amount of solid paraffines, melting upon the application of heat and evidently produced by nature from petroleums containing little or no solid paraffine. Solid or semi-solid residues produced from probably similar oils by artificial processes are sometimes called asphalts, but should properly be termed oil asphalts. The more common types of native asphalts are known by the name of the locality in which they occur, such as Trinidad, Bermudez, Maracaibo, Cuban, California, etc. Native asphalts with few exceptions contain water, extraneous organic or vegetable matter and inorganic matter such as clay, sand, etc.[1]

Third. Solid or semi-solid native bitumens. Solid or semi-solid bitumens obtained by refining petroleums, or solid or semi-solid bitumens which are combinations of the bitumens mentioned with petroleum or derivatives thereof, which melt on the application of heat, and which consist of a mixture of hydrocarbons and their derivatives of complex structure, largely cyclic and bridge compounds.[2]

I could go on indefinitely through the literature and show that most every author has given his own definition. This chaotic condition is receiving serious attention by several different societies at present.

Sources of Natural Asphalt

With this brief and general outline let us proceed to the description of the two sources of native asphalt from which the largest amount of ashphalt has been pro-

[1]Office of Public Roads, Department of Agriculture, Circular 93.

FIG. 1 RELATIVE LOCATIONS OF TRINIDAD AND BERMUDEZ ASPHALT LAKES

*Presented at the Dec. 8, 1919, meeting of the New Jersey Chemical Society, Newark, N. J.

†Chief chemist, Technical Department, Barber Asphalt Paving Co., Maurer, N. J.

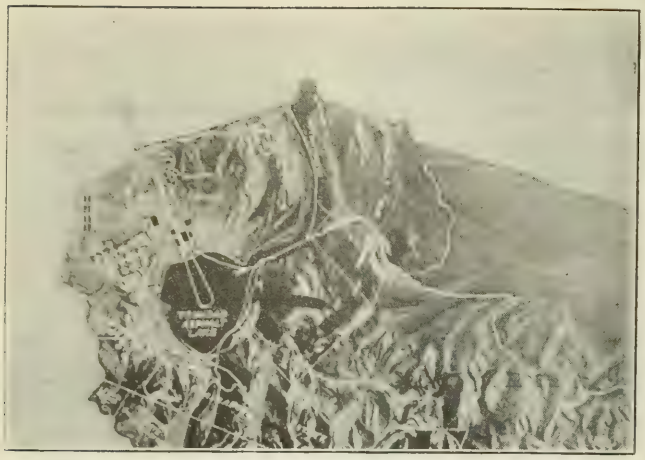

FIG. 2. RELIEF MAP SHOWING LOCATION OF TRINIDAD ASPHALT LAKE

duced, namely, Trinidad and Bermudez Lakes. The two lakes are situated in South America; the Trinidad Lake on the western coast of the Island of Trinidad in the British West Indies, and the Bermudez Lake on the eastern coast of Venezuela about thirty miles inland by air line. The relative locations of the two lakes are shown in Fig. 1. The Gulf of Paria, about eighty-five miles in width, separates the Island of Trinidad from Venezuela.

The island is about 700 miles north of the Equator and about 2,000 miles south of New York City. Its area is about 1,700 square miles, or less than the area of the State of Delaware. The climate is tropical, but is favored by the trade winds which tend to ameliorate the tropical temperature, averaging as it does about 85 deg. F. the year round, never varying more than 20 degrees. The only difference between one season of the year and another is the difference in rainfall.

Description of Trinidad Lake

The Trinidad Lake, and "lake" best describes it, is situated about one mile from the sea and about 138 ft. above sea level. Fig. 2 is a relief map showing the exact location of the lake. It is about 114 acres in extent. Its surface is undulating, the mass of asphalt seemingly lying in large folds, and where these folds meet there is a crevice formed, varying in depth from a few inches to a few feet in which rain water constantly stands, forming miniature canals. This characteristic formation is illustrated in Fig. 3. The mass is in imperceptible constant motion, which can be detected only by noting the relative position of the miniature canals at various times. This motion is also indicated by its behavior after digging, as will be described later on. Fig. 4 shows one edge of the lake.

Depth of the Lake Unknown

The greatest depth of the lake has never been found. In 1893 a series of borings were made, and the one at the center of the lake was carried to a depth of 135 ft., the entire depth being through solid asphalt of uniform character and composition, but the boring had to be abandoned, as the tube or casing had been carried so far from the vertical (one foot in six) as to render any further boring valueless. The depth found, however, indicates an almost inexhaustible supply of this wonderfully uniform material, for while mining has been carried on continuously for over thirty-eight years, the level of the lake has dropped only 6 or 8 ft. in all that time. This would seem apparent, for there is a perceptible rise in the center of the lake, but the new material is either of the same character or replenishment must be very deep, else the borings would have indicated a change in character. The borings near the edge of the lake indicated considerable slope to the sides, and it is believed the lake rests in a bowl-like depression, probably an extinct mud volcano.

Digging and Transporting Crude Trinidad Asphalt

There is a narrow-gage road and endless cableway running from the refinery out over the lake, and turning in a large semi-circle so as to traverse as much of the lake as possible, returning to the starting point. This road is not ballasted, yet there is very little sinking of the ties into the asphalt. A train consisting of several small flat cars, each car carrying a dumping bucket of about 500 lb. capacity, is pulled over this track by an endless cable running over the ties, and by means of a portable clutch a native sitting on the front of a train is able to start or stop the train at will. The natives dig the solid asphalt with broad mattocks and load the chunks into the cars by hand. The space left after a day's digging is completely filled within forty-eight hours, which is another proof of the continual motion of the mass of asphalt. After loading, the cars are pulled either to the refinery or the terminus of an endless overhead cableway which carries the loaded buckets down hill and out over the dock to the steamer, the loaded buckets going down hill, producing sufficient power to pull the empty buckets up hill. The crude Trinidad asphalt, as it is called, is shipped in bulk in the holds of steamers, to all parts of the world, but during transit amalgamates into a solid mass and has to be dug out again.

Description of Bermudez Lake

We will now journey for a moment into the wilds of Venezuela to take a hasty glance at the Bermudez Lake. The only means of approach from the Gulf of Paria is by steamers up a desolate river known as the San Juan. For five hours we see nothing but mangrove swamps on either side of this wide and placid river, the only signs of life being the customs officials' hut at its mouth, and myriads of multi-colored birds. The last five miles of the trip is up a tributary of the San Juan known as the Guanoco River. This really is a deep creek, it being so narrow that the steamers cannot turn, so they turn at the fork of the two rivers and

FIG. 3. WATER STANDING IN FOLDS ON SURFACE OF TRINIDAD LAKE

back up to the dock at Guanoco in order to have a straightaway course when loaded. We take a narrow-gage road at Guanoco for a seven-mile trip through jungleland. Indeed, you cannot step off the ties of the road without going up to your ankles in water. All through this jungle you see the beautiful tropical flowers and birds of many colors, but never a note of song from the birds or a sweet scent from the flowers.

Bermudez Lake (Fig. 5) is about 2,000 acres in extent and varies from 3 to 10 ft. deep in those parts that have been worked. It is not quite as hard as the Trinidad Lake and the ties supporting the railroad have to be shifted frequently. There is considerably more water to contend with here, as the seasons vary by one

FIG. 4. EDGE OF TRINIDAD ASPHALT LAKE

being wet and the other very wet. There is also considerably muddy silt to be mucked off the top, this mud being washed in by the heavy rains from the hills to the west. Owing to this mud you will find more vegetation on this lake than on the Trinidad Lake.

Handling Crude Bermudez Asphalt

The asphalt is loaded by hand into dump cars which are pushed by natives in trains of three or four cars to an elevated track at the edge of the lake, there to be dumped into wooden skips. These skips are hauled on flat cars seven miles to the steamer's side at Guanoco, lifted by the steamer's winches and dumped into the vessel's hold. The Bermudez crude runs together while in transit, the same as the Trinidad, and has to be dug out again upon its arrival at destination.

Refining Crude Asphalt

As the operation of refining is the same for both asphalts, we will describe more fully the Trinidad.

As obtained crude, the Trinidad contains approximately and uniformly through all cargoes, 39 per cent of bitumen, or that portion that is soluble in carbon disulphide, the accepted solvent of the asphalt industry for determining bitumen, 32 per cent of mineral and other matter, and 29 per cent of water. For comparison, Bermudez crude varies as to its water content, averaging about 25 per cent, 1 to 3 per cent of mineral matter and 68 to 72 per cent of bitumen. The refining in either case consists in driving off the water in a steam-heated still open at the top, at a temperature of about 350 deg. F. It takes about eight hours to refine a still of fifty to seventy tons. It is then either drawn off into slack barrels, such as cement is shipped in, surface cooled by water to prevent splashing while being hauled about the refinery yard and shipped direct to customers or is fluxed before drawing.

Fluxing Refined Asphalt

Fluxing of a refined asphalt consists in adding a predetermined quantity of a petroleum residuum, or flux, which flux is bought under stringent specifications assuring a uniform material suitable for paving and other purposes. Refined asphalts have a consistency or penetration of from about 2 deg. for Trinidad to 20 deg. for Bermudez. This consistency is determined by means of a sewing needle of certain size and make, under a fixed load acting for a fixed time at a standard temperature and a degree of penetration is ten times the number of millimeters the needle sinks into the asphalt. The refined is too hard for use in paving operations. The proper consistency is dependent upon climatic and traffic conditions, as well as the grading of the mineral aggregate with which it is mixed to produce a paving mixture. The fluxed asphalt must not be too hard in cold weather and yet not too soft in summer. You have all noticed and I presume heard unfavorable comments upon the softness of some sheet asphalt pavements in the summer time. Did you ever see a sheet asphalt pavement with heel marks, horses' calk marks or tire tracks in it in winter? What becomes of them? They iron out, and a pavement that does not mark a reasonable amount in summer must be viewed with suspicion. It will probably be too hard in winter. This is one feature in which technical control has been and will be of much assistance to the paving industry.

Asphalt Cement

When the refined is fluxed it is called an asphalt cement, as it is used to cement particles of mineral matter together, and after a still has been fluxed to proper penetration or consistency it is shipped in either single or double head hardwood barrels, according to

FIG. 5. VIEW OF BERMUDEZ ASPHALT LAKE

its consistency, and is ready for use when received, except that it has to be remelted. Some customers prefer to flux the refined themselves; others desire it ready fluxed, and for country road purposes it is shipped ready fluxed in the majority of cases.

Asphalts have been applied to many different uses in the past few years and the simple fluxing to varying degrees of consistencies referred to above does not ade-

FIG. 6. LOADING DOCK AND STEAMER IN GUANOCO RIVER

quately describe conditions today. Some uses require the softest, while another use requires the same melting point but a much harder consistency. Such variations are obtained by proper blending of two or more asphalts or the incorporation of materials other than asphalts. Obviously the type of material suitable for use in hard rubber compounds would not be suitable for saturating canvas to produce a waterproof and mildew-proof piece of goods. Neither of these products would be applicable for building tank linings to withstand temperatures up to 120 deg. F. and mixed acids (such as sulphuric and nitric of about 25 per cent strength) such as are met in the dye industry.

Colloidal Mineral Matter in Trinidad Asphalt

I would like to refer now to the mineral matter that occurs in Trinidad Lake asphalt. It appears to exist in a colloidal state, so we will consider that subject very briefly, for while many of you are, no doubt, familiar with this subject, yet those present who have not ventured into this realm of the "poetry of chemistry," as it has been aptly termed, will no doubt find something of interest to their own problems or difficulties, for colloidal conditions exist all around us; in fact, Dr. Fisher would have us believe the human system is more or less a colloidal one, the tissue structure being a water-in-oil emulsion, which is another way of describing a water colloidal dispersion in oil.

Graham's Investigation of Colloids

The first systematic investigation of and the name "colloids" are due to Thomas Graham, whose results were published in numerous papers between 1861 and 1864. His discoveries may be briefly summarized under two general heads. In studying dialysis of various substances, i.e., the diffusion of dissolved substances through organic membranes like parchment into the pure solvent, he found that some of them passed freely through the membrane into the surrounding solvent, while a number of others failed to do so, or diffused at an extremely slow rate. Generally speaking, the former were bodies which were known to crystallize, while the latter, like glue, gelatine, gum arabic, etc., were known only in the amorphous condition. Graham accordingly divided soluble bodies into two classes, crystalloids and colloids (from colla, meaning glue).

The second discovery was that a number of substances generally considered as insoluble could, by appropriate methods, be obtained in what at first sight appeared to be real solutions. They did not, however, diffuse through parchment, and on account of this property they were called "colloidal solutions" or simply "sols," which term has now become generally accepted. These "sols" showed a further striking peculiarity, which distinguishes them sharply from true solutions, as extremely small additions of electrolytes or reagents such as ordinarily would not react at all with the dissolved substances caused radical alterations in the condition of the solutions. Silicic acid sol sets to a transparent jelly when a trace of carbon dioxide is added thereto, and a ferric hydroxide sol is immediately broken down by a slight addition of sodium sulphate with the precipitation of the ferric hydroxide as a flocculent mass. Obviously these were phenomena quite different from known reactions of a purely chemical nature and the sols had to be considered as systems differing from ordinary true solutions.

Ultra-Microscope Aids Study of Colloids

Since Graham's time the whole subject has been studied by an ever-increasing number of investigators, both physicists and chemists, with new methods and appliances, the most important of which has been the ultra-microscope, invented in 1905 by Zsigmondy and Siedentopf, which even in that short time has enormously enlarged our knowledge of colloidal solutions. The principal step forward in theory has been the proof, now quite conclusive, that "colloids" in Graham's sense are not a definite class of substances, but that by suitable means and methods a very large number of bodies can be prepared in a colloidal condition, which indicates and is generally accepted that it is a *state* and not a *form* of matter.

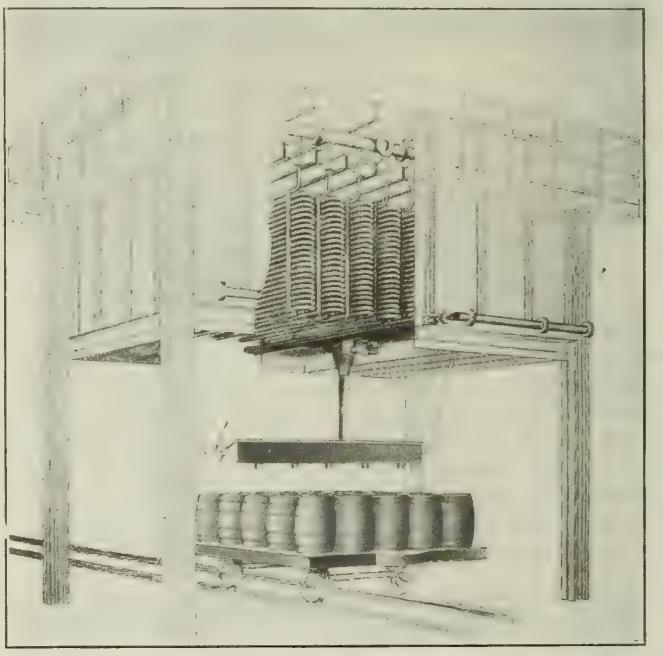

FIG. 7. STEAM STILL FOR REFINING ASPHALT

Bancroft's Views on Colloidal State

More recently, W. D. Bancroft has stated that Graham's view that a colloidal substance must be amorphous has been dropped and we now call a phase or state of matter colloidal when it is sufficiently subdivided, not committing ourselves definitely as to the degree of subdivision. Colloidal chemistry appears to Bancroft as the chemistry of bubbles, drops, grains, films and filaments.

FIG. 8. STORAGE PILE OF REFINED LAKE ASPHALT IN SLACK BARRELS

All surfaces, both of solids or liquids, have the power of adsorbing solids, liquids, or gases. A familiar instance of this is the formation of an air film or water film on the surface of glass. It is perfectly familiar to all of us that small drops of a liquid will coalesce to a single drop when brought in contact. It is not so familiar that solids also coalesce when brought in contact, because solids, as we know them, have a film of air on the surface and we do not actually bring them in contact. Cushman and Goggeshal report in their work that a powder which would pass a 200-mesh screen surged like a liquid. The film of air was so large relatively to the mass of the particles that they were really dealing with little elastic balls having a hard core. Heating drives out the air film and tends to make solids more malleable so that pressure brings more points into actual contact. We can join two pieces of glass while they are still very viscous, and we join two pieces of platinum in the laboratory at temperatures far below its melting point. Cleaning of surfaces prior to soldering is another familiar instance, although here we have the question of clean surfaces as well as absence of air film.

In the above discussion Bancroft is attempting to develop the thought that solid grains or liquid drops will agglomerate if actually brought into contact, and to keep them from doing so we must have a surface film of some sort. Dirty mercury will remain as a single liquid mass indefinitely. If we disintegrate the mass, a film will form over each drop and will prevent the drops from coalescing. The case of breaking this mass of mercury depends upon the surface tension of the mercury.

Brownian Movement of Fine Particles

If we drop a stone into water, it sinks rapidly; if we grind the stone into coarse particles, these sink less rapidly; if we continue to grind finer and finer, we finally reach a point or state that we would expect the particles to sink the slowest, the rate, of course, being a function of their diameter. This is not the case, however. When the particles are subdivided below a certain size, they actually fail to settle out. They then take on a constant unceasing motion known as the "Brownian movement." This movement was first noted in 1827 by Dr. Brown, a botanist, after whom it is named. The movement is composed of an oscillating motion of particles around a central position and an erratic translatory motion.

This motion decreases as particles grow larger and ceases entirely if the diameter exceeds a certain size. Various suggested causes, such as vibration, convection currents due to changes of temperature or of concentration were gradually eliminated by experiment, and it became evident that the movement could hardly be due to any transient cause.

The study of the phenomena received an enormous impetus by the invention of the ultra-microscope, as the very small particles disclosed by it for the first time showed it so vividly that Zsigmondy was inclined to look on it as something differing not only in degree but also in kind from the Brownian movement. Methods were devised which facilitated the measurement of the amplitude of oscillation—that is, the time between two similar positions.

Theory as to Cause of Brownian Movement

Since then various mathematical relations between these quantities have been developed, but the theory as to the actual cause of this Brownian movement is still in dispute, although the most generally accepted theory seems to be that the whole phenomenon conforms to conclusions drawn from the kinetic theory and that there is no essential difference between this motion and molecular motion. The stability seems also to be intimately connected with the electric charge, as it has been shown generally that colloidal particles are so charged.

Ultra-Microscopic Study of Mineral Matter in Asphalt

For many years the insistent presence of a small percentage of mineral matter in all extracted bitumen from Trinidad Lake asphalt baffled the operators, and while we all felt it was a very finely divided clay, yet it was not until 1914 that Clifford Richardson initiated the work that finally showed us these particles in the ultra-microscope.

Richardson's Theory of Asphalt Formation

How this clay occurred in this manner is explained by Mr. Richardson briefly as follows:

"The crude asphalt in the lake consists of a complex system of several phases, gaseous, liquid and solid, organic and inorganic, more or less in equilibrium, displaying colloidal properties of industrial as well as scientific interest. The asphalt owes its origin to certain geological conditions existing side by side in that locality. Oil sands occur at different depths, which contain vast quantities of petroleum, as has been demonstrated by the many wells which have been successfully sunk, a petroleum of unique character, differing from any previously known, and of a highly asphaltic nature. Rising toward the surface along some line of least resistance, the petroleum meets the paste of fine silica and clay which forms the mud of the spring. With this the oil becomes emulsified, probably by the action of the natural gas which accompanies it at very high pressure. In the lapse of time the entire crater of the spring has been filled with the resulting material and it has overflowed the rim, running down the slopes to the sea.

"Fresh material is in process of formation today and issues at several points on the surface of the deposit of a consistency so soft that it can be readily molded into balls with the hands, without adhering to them owing to the free water with which it is associated. This

so-called "soft pitch" is also accompanied with natural gas of unusual composition, containing, in addition to the hydrocarbons usually found in such gas, carbon dioxide and hydrogen sulphide, in some localities in the neighborhood of the deposit as much as 33 per cent of the former and 3.5 per cent of the latter. At the same time the soft pitch itself is evolving gas, either the result of the release of pressure or of a reaction going on between the bitumen and the mineral matter it contains, this gas consisting largely of hydrogen sulphide and carbon dioxide, probably the latter cause, as it continues for years after the material has been exposed to the air, while if the soft asphalt is sealed up in a tin can the latter will explode in the course of time from the gas pressure developed.

"The main mass or older form of the asphalt in the crater is sufficiently hard to make it possible to flake it out in large pieces of from 50 to 100 lb. in weight. In this form it resembles an exaggerated Swiss cheese owing to the gas cavities it contains. While brittle enough for this, an excavation of some depth at any point is filled up and obliterated in twenty-four hours by the flow of asphalt from the adjoining material. Large masses of the asphalt taken from the deposit and kept in storage, without lateral support, present all the features of the glacial flow of ice.

"The asphalt, therefore, originating in a soft condition as demonstrated by the fresh material, which is constantly being formed and which emerges near the center of the deposit, becomes hard in the course of a year or two. The cause of this and of the evolution of the gas which is observed may be attributed to the presence of a catalyzer. As will be shown, the asphalt contains clay in highly dispersed condition, carrying adsorbed ferrous sulphate, which may play such a role."

Colloidal Suspensions of Clay in Pure Bitumen

In the endeavor to reproduce these conditions, clays from many different sources, including clays from oil springs found on the Island of Trinidad, have been experimented with in many ways and that method showing the most promise is to make a clay slurry with water, adding this to a pure bitumen at a temperature below that of boiling water and slowly cooking out the water. This method results in some colloidal particles in the bitumen, but not nearly approaching the number per unit of volume as found in the lake asphalt.

Examination of Bitumens by Ultra-Microscope

In preparing a bitumen for examination by the ultramicroscope, it is best to have about a 10 per cent solution of bitumen in benzol. After swinging for one-half hour or more in a centrifugal machine it can be examined immediately, or if it is desired the solution can be allowed to stand for several months or filtered through a Chamberland filter. Whether one or all of these methods are followed, we still find the particles persisting in the solution.

Effect of Colloidal Clay on Physical Properties

These minute particles of clay no doubt adsorb the bitumen, creating a surface energy far in excess of any type of mineral filler added to a bitumen in the usual dry way such as in making a sheet asphalt mixture. If we add to one portion of a bitumen a percentage of dry clay and to another portion of the same bitumen add the same quantity of the same clay, but in the form of a slurry, and the resulting mixtures are rolled out in the form of a long cylinder and coiled spirally in a tube, it will be noticed in a short time that the spiral made of dry clay and bitumen is flowing together and deforming generally, whereas the one made with the wet clay holds its shape indefinitely. In other words, the colloidal clay has had a greater physical effect in the mechanical modification of the bitumen than the dry clay. It has made a more stable bitumen as regards its susceptibility to temperature changes without any chemical modification of the hydrocarbons composing the bitumen.

This experiment conclusively shows the effect of increased adsorption due to the colloidal state of the mineral matter in Trinidad Lake asphalt. This adsorption increases the surface tension or energy of the film, thus increasing the stability.

Awakened Industrial China

In speaking before the Chicago Foreign Trade Club recently, Julian Arnold, commercial attaché of the U. S. Department of Commerce, reviewed the developments which have been made in the Orient in the past twenty years, with especial reference to China. There has been during that time a modern educational system installed, the growing of opium has been wiped out, a modern press is being developed, with over 300 newspapers published regularly, and a national spirit has been awakened.

In the line of foreign trade possibilities there is a population of 400,000,000 people as compared with 70,000,000 in South America. There is as much coal in China as in the United States. They also have iron ore, antimony, zinc, lead and tin, and these resources are now being opened up. Eighty-five per cent of the population is engaged in agriculture, with the farms averaging five acres each. The great outstanding problem is the lack of transportation. Give China 100,000 miles of railroads and these markets will be opened to the entire world, developing this section of the earth to ideas of modern industrialism.

The Shanghai Chamber of Commerce is doing much to help the American manufacturer in finding markets in the Orient. American goods are popular because of the quality marketed. The language must be taught in our universities. The cable service should be improved. As conditions are today this country offers the greatest trade opportunities in the world.

Extension of Laboratory Facilities for Analysis of Imports in Brazil

A law of Jan. 13, 1920, provides for the immediate establishment of laboratories for the analysis of imported products in the custom houses of Santos, Porto Alegre, Corumba, Recife, Bahia, Parahyba, Fortaleza, Maranhao, Belem, and Manaos, with the gradual extension of such facilities to all the custom houses of the republic for the purpose of preventing the introduction of articles injurious to the public health. A fee of 2 per cent of the total import duties, payable in paper currency, is to be charged for the analysis of the following articles: All kinds of fabrics; chemical products, drugs, and pharmaceutical preparations; canned meats and fish, excepting codfish; vegetables; starches; cheese; butter; all other alimentary products; and articles used in the preparation of foods and drinks.

General Sibert and the Chemical Warfare Service

By Paul Wooton

NO SURPRISE was occasioned among his close friends when Major General William L. Sibert requested that he be relieved of the command of the Fifth Division at Camp Gordon, Ga., and be placed on the retired list of the Army. While no complaint or comment is coming from General Sibert, it is well known in Washington that his heart was in the Chemical Warfare Service and despite determined efforts to take up army post life again, he found it impossible to do full justice to his assignment. General Sibert expects to embark in the near future in active private work.

While General Sibert is not a chemist, he is recognized as having been the most important single factor in the development of the Chemical Warfare Service. He regarded the upbuilding of this branch of the Army as the crowning achievement of his military career. He is understood to be very grateful for having been permitted to continue his work to the point where he persuaded the Congressional committees in charge of military legislation that the development of chemical warfare should be pursued actively and entirely independently of the other subdivisions of the War Department.

GENERAL WILLIAM L. SIBERT
Former Director of the Chemical Warfare Service, Who Has Applied for Retirement from the Army

In view of the personal feeling that it was necessary to arouse in thus opposing the wishes of the General Staff, it is believed that General Sibert realizes that the work now can be carried on best by another, and is more than satisfied with the assurance that chemical warfare is not to be a subdivision of an existing War Department agency and that active development of this branch of the military service is to be continued. The wisdom of such conclusion is evidenced by the growing interest within the War Department in the Chemical Warfare Service, and it is believed now that all concerned will co-operate to secure the maximum benefits from the work which will be carried on by that arm.

In the view of his associates, General Sibert's greatest achievement came during the war in bringing the agencies engaged in chemical warfare activities into a cohesive whole. When he was assigned to the gas warfare section, as it was known then, General Sibert found the manufacture of masks being conducted under one agency, the manufacture of gas and the filling of shells under another, while the training of gas troops was under still other direction and a fourth agency was in charge of gas research.

Good work was being done in each particular line, but the greatest difficulty was being found to secure the desired co-ordination of all the activities entering into gas warfare. This unification of the chemical warfare activities was made just in the nick of time. Operations at the front were being hampered by the lack of certain materials not properly supplied by some of the former subdivisions. The situation became so bad that a cable was actually sent from headquarters in France to General Sibert, advising him that it would be necessary to stop the offensive use of gas troops unless these materials could be made available in the very near future. With his then unified service, General Sibert found no difficulty in bringing about the quantity of production required.

General Sibert's experience in the field was particularly valuable to him in making up the work in this country to meet practical conditions existing on the front. Through the lack of intimate touch with field conditions, the manufacture of vincennite continued on a considerable scale in this country some time after its worthlessness under battle conditions had been demonstrated to the satisfaction of the chemical officers with the expeditionary forces. Vincennite, which promised so much under laboratory and experimental conditions, failed to give results in actual battle because anything less than killing quantities of the gas in no way impaired the effectiveness of the enemy. It was in such matters as these that General Sibert proved of such help to the situation just at the time when it was most critical.

The fact that General Sibert knew only the chemistry of the West Point graduate and of the engineer led him to lean heavily on the prominent chemists with whom he surrounded himself. He had no preconceived theories of his own, which might have been the case had a chemist been thrust into a work concerning which there were so many uncertainties. His lack of technical chemical knowledge led him to concentrate on the practical phases of the service, an aspect now held to have been equally responsible with the remarkable technical achievements for the success of the American Chemical Warfare Service in the World War.

Current Events
in the Chemical and Metallurgical Industries

New Jersey Chemical Society Holds Annual Meeting

The New Jersey Chemical Society is one of the progressive organizations of that state. The steady, remarkable growth which it is enjoying was evidenced in more ways than one at the annual meeting, held at Achtel-Stetter's, Broad St., Newark, on Monday evening, April 12, for despite the handicaps brought about by the railroad strike, there was a good attendance and an excellent program, with good-fellowship prevailing in overflowing measure. The reports presented showed conclusively that the association has become an important factor in this industry in the state, and its work is receiving more and more attention.

The organization is in a way still in its infancy. It was organized in 1918 with primary purpose to bring into closer contact those in the trade, profession and business, and at the same time permit those interested in chemical work to participate in its proceedings. Many monthly meetings have been held and a real, concrete interest has been secured for the benefit of all concerned. To Carleton Ellis, of Montclair, N. J., a large measure of credit is due, for as president of the association since its inception, and greatly instrumental in its formation, he has piloted affairs in an able, masterful way, giving considerable time and attention to the work, with no little effort devoted to increasing the membership.

Election of Officers

Mr. Ellis was re-elected president at the annual election, thus filling the chair for the third consecutive time. R. P. Calvert, who has been acting secretary of the association, was elected vice-president, succeeding Frederic Dannerth, who has recently taken up residence in Brooklyn. D. K. Howard was re-elected treasurer, while J. A. Wilson was appointed secretary. Those comprising the board of governors for the ensuing year will include H. G. Cawley and G. A. Armstrong. Others acting on this board during the year past are H. B. Baldwin, R. P. Calvert, W. A. Lucas, C. P. Titus, F. D. Crane and E. G. Little.

The first year book of the association has been published, and is a comprehensive and valuable volume. It reviews the association's activities up to a recent date and sets forth a list of the chemical and affiliated industries now operating in New Jersey. Incidentally, this list makes a fine showing, for the broadening of the industry in this section during late years is generally well known.

The program for the evening was preceded by the usual fine dinner, which was thoroughly enjoyed by those assembled. The principal addresses were made by Linn Bradley, of East Orange, and J. V. Meigs; the first dealt with the development of the potash industry in the United States, while the latter covered the subject of alcohol and other motor fuels as substitutes for gasoline.

Mr. Bradley, as chief engineer for the Research Corporation, of New York, has had a broad experience in the potash branch of the industry and speaks with authoritative and definite knowledge of this subject. He has given particular attention to the matter of potash recovery and devoted a large part of his paper to this phase of work.

He spoke of the installation of potash recovery plants at various cement mills, the first successful plant of this nature being that of the Riverside Portland Cement Co., at Crestmore, Cal., a development which came about after the installation of the Cottrell processes at this works for dust elimination.

Reference was made to the recovery of potash as a byproduct of blast-furnace operation, showing extensive accomplishments in this direction. The initial work of this character developed as a result of investigations at the plant of the Bethlehem Steel Co., at South Bethlehem, Pa. With the potash balances made, iron ores have been found in various parts of the country that give as much as from 1 to 3 per cent of potash, notably in the Alabama district, and yet carry sufficient iron for profitable blast-furnace operation.

A particularly interesting mention covered the forthcoming activities of a large potash corporation now building a plant in New Jersey for the production of potash from what is termed "New Jersey green sands." This plant, located in the Raritan River section, will be one of the largest works of its kind in this part of the country; it will be devoted to a varied, yet affiliated line of manufacture, including lime, potash salts, potash brick, green sand residue and other products. The company has acquired extensive green sand properties, containing a percentage of potash, near Eatontown, Monmouth County, and will use this as the source of supply. The process covers the heating of this so-called green sand mineral with lime for the extraction of potash.

Gasoline Substitutes

Mr. Meigs in an interesting talk outlined the necessity for the development of practical substitutes for gasoline, particularly in the line of fuel for automobile motors. He said that figures made public by oil experts indicated that native supplies of crude oil would be exhausted at a not very remote date. At the present time alcohol, he pointed out, gave evidence of being the most promising substitute, with shale oil closely allied in this connection. Various methods of obtaining alcohol were also considered by Mr. Meigs, dealing with standard practice of today.

Imports of Scientific Apparatus

Imports of scientific apparatus during February of 1920 were valued at $2,555. This compares with imports during the corresponding month of 1919 of $2,092. Imports of scientific apparatus during the eight months ended with February were valued at $48,191, which shows a decrease from the imports during the corresponding period of the year previous, when they totaled $69,113.

Further Nitrate Hearings

The hearings before the Senate Committee on Agriculture regarding the proposed fixed nitrogen corporation were continued daily from Thursday, April 8, until the following Tuesday. Supplementing the general criticisms (reported last week in CHEMICAL & METALLURGICAL ENGINEERING), Mr. Washburn, president of the American Cyanamid Co., again emphasized that there is no place in the present market for the material which the administration expects to make at Muscle Shoals.

E. Kilburn Scott called the attention of the committee, in Mr. Washburn's presence, to certain contradictions which he alleges will be found in Mr. Washburn's present statements and those which he made in 1916, when he urged the erection of the Muscle Shoals plant. Mr. Scott says that Mr. Washburn is now condemning his own plan.

LANDIS SUMMARIZES OBJECTIONS

W. S. Landis, chief technologist of the company, also was on the stand, taking up particularly other testimony which was presented to the committee and criticising various alternate proposals to the production of certain chemical products at these plants, particularly the possibility of making calcium nitrate, ammonium nitrate and ammonium nitrite.

In résumé of the objections of the company to continuance of Muscle Shoals operations, he stated three reasons, as follows: (1) The corporations cannot easily compete with the Government, which charges no amounts to operation for taxes, etc. (2) Operation by the Government will unreasonably take away from existing companies their patronage in fields which they have developed at considerable expense to themselves. (3) Continuance of the plant operation on the basis proposed will amount to an appropriation by the Government of processes and patents which belong to private interests and are beyond the contract rights of the Government.

Special emphasis was laid upon the point that completion of the dam operation at the present high prices of materials was considered commercially wrong. Costs of materials used in the Government estimates for the plant operation were also criticised; particularly the charge for coke at $6 per ton, was characterized as too low and the charge of 5c. a lb. for electrodes was criticised. However, explaining these charges, Colonel Burns of the War Department stated that the best estimates as to stable future conditions were taken in these points and the correspondingly low income from the sale of the products had been assumed. Therefore it was his belief that these low prices for materials were amply offset by the fact that $65 per ton was the amount estimated as the Government income from the sale of the ammonium sulphate, whereas present market conditions are very much above this figure.

SCOTT SUGGESTS USE OF ARC PROCESS

E. Kilburn Scott of New York City also appeared before the committee favoring the bill for the continuance of the plant operation by urging that the arc process should be used in part in the course of development. An extensive presentation of the claimed merits of this process and the advantages believed to accompany its use at Muscle Shoals under present conditions were set forth.

The War Department requested opportunity to reply to the criticisms and the hearings were adjourned to be resumed on Tuesday morning, April 20, at which time the nitrate division was to resume its arguments.

GRAHAM COMMITTEE TO REPORT SOON

Within two weeks Representative Graham of Illinois, chairman of the committee investigating expenditures in the War Department, expects to address the House giving the conclusions of the majority of the committee as to the activities of the Government looking to the manufacture of nitrogen.

War Department Releases Sodium Nitrate

During the discussion in the House of Representatives of the resolution authorizing the Secretary of War to turn over a portion of the reserve of nitrate of soda it was revealed that the Government's reserve was purchased at a cost ranging from $56 to $84 a ton. It was declared on the floor of the House that there would be no loss to the Government in the transaction, as the price which would be received would be in excess of the original cost of the nitrate.

The resolution as drafted and approved by the Secretary of War called for the use of 50,000 tons of the War Department's reserve. The House approved the amendment, however, increasing the amount to 100,000 tons. It also amended the resolution previously passed by the Senate so as to allow the outright sale of the nitrate rather than require replacement with a similar quantity of nitrate.

In an effort to make profiteering in this material more difficult two additional amendments were adopted. One provided that "not less than one ton or more than 100 tons may by sold to any purchaser." The other amendment requires the Secretary of War to report to Congress not later than Dec. 6 the names of all the purchasers together with the prices realized from each sale.

Zinc Tariff Bill Reported Favorably

After a long delay the Senate Committee on Finance has reported favorably, without amendment, the zinc tariff bill which was approved by the House on Sept. 2. Zinc-bearing ore containing 25 per cent or more of zinc is to be dutiable at 1c. per lb. on its zinc contents. A strenuous effort was made to induce the committee to authorize a duty of 2c., but after careful consideration this request was denied.

In addition the bill provides duties as follows: On zinc oxide and white pigment containing zinc, but not containing lead, dry, 1c. per lb.; ground in oil, 1¼c. per lb.; white sulphide of zinc, 1½c. per lb.; chloride of zinc and sulphate of zinc, 1c. per lb.

In reporting the bill to the Senate, Senator Watson pointed out that the American zinc-producing industry is in a serious condition. Out of eighty-seven mills, which were operating in the Webb City district of Missouri, only two now are working. In Webb City, he asserted, one-third of the inhabitants have left. In addition, he said, 400,000 tons of zinc ore are piled on Australian docks ready for shipment. Since this ore is a byproduct of lead-silver operation, the producers are willing to take any price they can get for it. He also pointed to the menace of Mexican production, which may increase rapidly if conditions in that country should permit.

Personal

A. W. AMBROSE of the U. S. Bureau of Mines has been appointed superintendent of the petroleum experiment station of the Bureau at Bartlesville, Okla. He succeeds W. P. DYKEMA, who has resigned in order to be able to devote more time to the natural gas investigations of the Bureau.

R. L. COMSTOCK, formerly of the Brown Co., Berlin, N. H., is now with the Warner Chemical Co., Cartaret, N. J., as plant chemist.

HARRIS D. HINELINE resigned as research engineer with the Westinghouse Electric & Manufacturing Co. to become a member of the faculty of the Science School of the Carnegie Institute of Technology, department of chemistry, Pittsburgh, Pa.

GEORGE P. HORN, formerly of the Service Bureau of the Portland Cement Co.'s Pittsburgh office, is now chief chemist of the Security Cement & Lime Co. He will have charge of the laboratories at the cement plant at Security, Md., and the lime plant at Berkeley, W. Va.

Dean DAVID MCKINLEY will remain in office as president of the University of Illinois, as recently confirmed by the board of trustees.

EDWARD MALLINCKRODT, president of the Mallinckrodt Chemical Co. of St. Louis, has been elected to the board of directors of the Laclede Gas Light Co. of St. Louis.

C. G. RICE of Boston has been elected president of the U. S. Smelting, Refining & Mining Co. to fill the vacancy caused by the death of William G. Sharp last July.

E. KILBURN SCOTT, consulting engineer, of New York, has recently been in Chicago and Western points on professional business. Mr. Scott has been called to Washington to testify before the Senate Committee on Agriculture relative to the arc process of nitrogen fixation.

FERDINAND L. SNYDER, formerly assistant engineer of the Baltimore Copper Smelting & Rolling Co., has resigned to accept the position of efficiency and assistant plant engineer, Portsmouth Cotton Oil Refining Co., Portsmouth, Va.

Dr. E. C. SULLIVAN has been elected vice-president of the Corning Glass Works, Corning, N. Y.

CYRIL S. TAYLOR has resigned from the Bureau of Standards, Washington, to go in the research department of the Aluminum Company of America at its laboratories at New Kensignton, Pa. Mr. Taylor expects to begin his work in the new position some time during June.

F. G. TRYON, who just has been appointed head of the mineral fuels division of the U. S. Geological Survey, is widely known among chemists from the fact that he was in charge of chemical and explosives statistics for the Council of National Defense during the early portion of the war, and later was in charge of statistics of chemicals, fuels and explosives for the General Staff.

Obituary

ROBERT TREAT SPICE, professor emeritus of chemistry at Cooper Union, who died April 8 in his seventy-fourth year at his home in Bloomfield, N. J., had been a teacher in various private and public institutions of New York and Brooklyn for more than forty years.

Chemistry and physics were his specialties. These subjects were taught by him at the Girls' Evening High School, in Court St., Brooklyn, in the late '70s; next at the Brooklyn Polytechnic Institute, and from 1888 to 1900 at the Girls' High School in Brooklyn. While occupying this last position he taught classes in chemistry and astromony in the evenings at Cooper Union. In 1900 he gave up all other work to devote himself day and evening to Cooper Union as professor of chemistry, retaining this post until obliged by failing health to retire in 1914.

THEODORE N. VAIL, head of the American Telephone & Telegraph Co., died April 16, in his seventy-fifth year. Bell invented the telephone, Vail made it a business success. Bell set out to prove and did prove that men could talk over wires, and still the obstinate world continued to poke fun at "Bell's toy." Vail caught and held a vision of this "toy" put to worldwide commercial use. He was the man of vast business capacity in the story of the telephone. He strung the first long-distance line, and the same world that had sneered at Bell called it "Vail's folly." He lived to direct the second largest corporation in the world, with 19,000,000 miles of wire.

Funeral services were held on Sunday, April 18, and at 11 o'clock, Eastern standard time, on that day the service on every Bell telephone throughout the country was suspended for one minute in tribute to the man who was for so many years the master of the organization.

Current Market Reports

The Non-Ferrous Metal Market

New York, April 19, 1920.—Prices of copper, tin, lead and antimony are unchanged. The decline of silver continues, the present quotation being $1.19½ per oz., against $1.26 last week. There has been a general stiffening in the price of scrap metals.

	Cents per Lb
Copper, electrolytic	19.25
Aluminum, 98 to 99 per cent	32@33
Antimony, wholesale lots	11.25
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	62.25
Lead, New York, spot	9.00
Lead, E. St. Louis, spot	8.70
Zinc, spot, New York	8.80
Zinc, spot, E. St. Louis	8.30

OTHER METALS

Silver	oz.	$1.19½
Cadmium	lb.	1.40@1.50
Bismuth (500 lb. lots)	lb.	2.50
Cobalt	lb.	1.50
Magnesium (f. o. b. Niagara Falls)	lb.	1.60
Platinum	oz.	142.00
Iridium	oz.	250.00
Palladium	oz.	142.00
Mercury	75 lb.	103.00

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	26.75
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	32.00
Seamless bronze tubing	34.50
Seamless high brass tubing	30.50

SCRAP METALS

	Cents per Lb. Buying Price
Aluminum, cast scrap	22.50 @24.50
Aluminum, sheet scrap	23.50 @24.50
Copper, heavy machinery comp	15.50 @16.00
Copper, heavy and wire	15.75 @16.00
Copper, light and bottoms	14.25 @14.75
Copper, heavy cut and crucible	16.25 @17.25
Brass, heavy	10.00 @10.25
Brass, light	8.50 @ 9.00
No. 1 clean brass turnings	10.00 @10.25
No. 1 comp. turnings	13.75 @14.25
Lead, tea	5.25 @ 5.40
Lead, heavy	7.00 @ 7.50
Zinc, scrap	4.25 @ 4.50

The Iron and Steel Market

Pittsburgh, Pa., April 16, 1920.

The iron and steel market became stagnant, except for the booking of some contracts for finished products, when the rail strike occurred and rendered a large part of the industry idle. Last Monday most of the blast furnaces tributary to the Connellsville coke region were banked, as is was certain no coke would get through, and day by day more capacity went down, as the byproduct ovens had no stocks of coal to speak of. The territory most affected was the Youngstown district, the Calumet (Chicago and Gary) and the Pittsburgh districts coming next. The East was less affected and the South very little. At this writing the strike seems to be waning rapidly, but it will be several days before there is anything like a free movement of coal and coke. It may be estimated roughly that nearly half the industry loses somewhat more than a week's output.

Such loss is a very serious one from the viewpoint of the moment, but the more natural viewpoint is the one at long range, for the whole problem of the iron and steel trade since the first of the year has been the question of recovery from the acute shortage of material that existed at the end of the old year. When could the industry "catch up"? Up to the time of the rail strike, as indicated in previous reports, production had been proving much larger than had been predicted in many quarters. The market, the one that still exists, was made on the basis of the shortage and the expectations of its being difficult if not impossible to produce enough to relieve the shortage. If production had been proving 10 per cent greater than expected, then the loss of output caused by the rail strike, say 2 per cent of a half year's production, may be compared with that 10 per cent, appearing insignificant by comparison. It may be said, of course, that the rail strike is only one trouble, and that there may be others, but the rail strike was more or less expected. During the steel strike in the late months of last year it was commonly remarked in the trade that just about the time the iron and steel industry got through with its own strike it would probably be crippled by a rail strike, this conforming to the familiar dictum that life is just one thing after another. Iron and steel production really has quite a bright prospect now.

The lethargy that manifested itself in the iron and steel markets upon the appearance of the rail strike was rather greater than would be expected in normal conditions, seeing that no one expected the strike to last any length of time, and the episode rather suggests that the market has a natural tendency to take things easy at this time. If consumers of pig iron and steel products have any particularly sanguine views as to the future, they have no opportunity to profit by making purchases, since it is obvious that prices are already as high as they are likely to go, and there is no incentive to buy except to insure the receipts of supplies. In the case of purchases from independent steel producers a premium over the real market basis has to be paid, for the independents are all asking more than the Steel Corporation or Industrial Board prices, and it has become moderately well established that the market is essentially taking those prices as a basis and other prices as containing delivery premiums above that basis. As to Steel Corporation sales, they continue to be made in greater volume than the shipments, the corporation customers showing no hesitancy.

Steel Corporation Tonnages

The March increase in the Steel Corporation's unfilled obligations was indeed greater than the February increase, the increases having been 389,994 tons in March, 216,640 tons in February and 1,020,075 tons in January. The increase in bookings from February to March was greater than appears in these figures, seeing that shipments in February were about 90 per cent of capacity and shipments in March about 96 per cent, so that there was a greater drain in the latter month on the order books. The March bookings become the more impressive when it is noted that the corporation's sheet and tin plate subsidiary was not selling to any extent, being booked up for the present half year and not having opened its books for regular second half business.

Last Tuesday, as expected, the American Sheet & Tin Plate Co. opened its order books for second half contracts with manufacturing consumers and third quarter contracts with jobbers, prices being those formerly adhered to, as contained in the Industrial Board iron and steel price schedule which became effective March 21, 1919. The pig-iron producers departed upward from that schedule as soon as they got the chance, late last year. Many of the independent producers departed downward from the schedule in April and May of last year, while afterward all independents got above the schedule. The Steel Corporation alone adhered strictly to the schedule right along, making no departures in either direction.

The prices set for sheets and tin plates are: Blue annealed sheets, 10 gage, \$3.55; black sheets, 28 gage, \$4.35; galvanized sheets, 28 gage, \$5.70; tin plates, 100-lb. weight, \$7 per base box. A base box is 31,360 sq.in., tin plate being sold by area, not by weight.

The independent tin plate manufacturers will, in general, adhere to the \$7 price in transacting business with regular customers, but probably more tonnage will be saved to sell on the prompt market, at the premiums expected to rule, than was the case when contracts were made for the present half year.

The independent sheet manufacturers, on the other hand, appear to be paying absolutely no attention to the action of the leading interest. They have all been quoting and receiving prices above the Industrial Board schedule, the prices varying according to time of delivery, and ranging from half a cent to several cents a pound above the Steel Corporation basis. An independent mill could hardly expect to sell its product for the entire second half of the year at a premium, while if all or a large number dropped to the Steel Corporation level the buyers might become suspicious. The present situation exists, and with it the independents can hardly do otherwise than adhere to their prices and sell what they can for such deliveries as the trade will take. Apart from this, there is the awkward fact with many of the independents that they must buy sheet bars and cannot get them except at much above the Industrial Board price of \$42. As high as \$90 has been paid recently, and regular tonnages could hardly be bought for third quarter except at \$60 to \$75. The sheet mill could not absorb such a difference.

Pig Iron

The pig iron market continues stagnant and no appearance is presented of prices tending to depart from the level previously quoted as the market: Bessemer, \$42; basic, \$41.50; foundry, \$42, f.o.b. valley furnaces, freight to Pittsburgh being \$1.40.

Ferro-Alloys

While complete information is lacking, it is a fair guess that production and consumption of ferro-alloys is about equally affected by the rail strike. The market is stagnant and is quotable about as follows: Prompt domestic ferromanganese, \$200@250 delivered; second half, \$180@200; electrolytic ferrosilicon, delivered, \$80 for 50 per cent and \$140 for 75 per cent; bessemer ferrosilicon, f.o.b. furnaces at New Straitsville and Jackson, Ohio, \$59.50 for 10 per cent, \$62.80 for 11 per cent and \$66.10 for 12 per cent.

Chemical and Allied Industrial Markets

New York, April 19, 1920.

The condition of these markets is probably as bad as it has ever been in the history of the trade. Demand on the part of users continues brisk, with no material at hand to dispose of these orders. Spot offerings are all nominal, as nearly all lines are bare and producers are unable to ship any goods in to relieve this condition. The combination of freight embargo and the truckmen's strike has effectually paralyzed any activity during the past week. It is reported that in some cases producers have large quantities of material waiting shipment but owing to the car or steel drum shortage they are unable to move it from their plants. A real shortage of raw materials in some markets is responsible for the present high prices, as demonstrated by listings of the coal-tar intermediates in general, which are practically nominal throughout.

PRINCIPAL PRICE CHANGES

	Today	Last Week	Last Month	Last Year
Formaldehyde	$0.60-$0.80	$0.60-$0.80	$0.90-$1.00	$0.22-$0.22¾
Dimenthylaniline	nominal	0.95-1.50	0.95-1.50	0.55-0.60
Epsom salts	3.60-4.25	3.60-4.25	3.60-3.75	2.25-2.35
Sodium bichromate	0.35-0.40	0.35-0.40	0.35-0.36	0.09-0.10
Turpentine	$2.50	$2.30	$2.20	0.77-0.78

Prices of chemicals in general remain unchanged, as there is very little trading being done at prices that would be a fair indication of the real market quotation. The spot market on some of the more active items is practically bare and whatever offerings are made are at extreme prices. *Alum,* potash lump, came up slightly under heavier demand and at the close of the week was listed at 8@8¾c. per lb. *Aqua ammonia,* 26 degree, drums, is listed at 8½@10¾c. per lb., against 7½@10½c. of last week. This rise has been caused by increased inquiry and a tightening of supplies. *Bleaching powder* remains in the same position, with very little material available. Nominal quotations of $4@$4.25 per cwt. still hold, while prices as high as $5 have been heard for spot material. *Cream of tartar* is firmer at 56@58c. for contract and 59@61c. per lb. for less than car lots. *Sodium bicarbonate* came up to $2.45@$2.60 per cwt., with foreign inquiry heavier than during the previous week. *Sodium nitrite* is back to normal, supplies on hand being fairly heavy; 22@26c. per lb. is now the average selling price on this item. *Glauber's salt* is in very poor condition and there is very little material being offered at $1.50@$1.70 per cwt. and as high as $2 is being asked for spot material.

Coal-Tar Products

The coal-tar products market presents the same general aspect as was previously reported. There have been very few material changes on the list, high water prices being generally sustained by the steady demand and shortage of supplies. *Napthaline crushed* is firmer at 8@9½c. per lb., *flake* holds at 9@10c., while *ball* grade, under considerable pressure, is listed at 10½@11c. per lb. *Phthalic anhydride* remained firm at 65@75c. per lb., with one concern making the price and holding it down to undersell the smaller competitors.

Naval Stores

The naval stores market is practically at a standstill, as there is scarcely any grade of rosin available and no turpentine at all to be had. Nominal quotation of $2.49 per gal. for turpentine has been received, but there is no material changing hands at this or any other price. This is principally due to the fact that no shipments from Savannah can be made because of the shipping strike along the coast.

Vegetable Oils

Activity in vegetable oils has fallen off slightly during the past week. Prices have not been materially affected, the listings in general holding firm at former levels. *Cocoanut oil,* Ceylon grade, is listed at 18½@19c. per lb. and *cottonseed,* crude, is firm at 17½@18c. per lb. while *linseed* is slightly easier than it was last week at $1.84, raw, car lots, $1.77 for raw, tank cars, and $1.87 per gal. for boiled, car lots.

Chicago, April 14, 1920.

A complete absence of spectacular features marks the chemical trade in Chicago for the past several weeks. Firmness characterizes prices in all lines, except in vegetable oils, and their weakness, which has previously been noted, has become accentuated. A decrease in the availability of acids is also noticed which apparently indicates higher prices to come. Alkali products are still at a premium and advances continue to be registered.

One element that contributes largely to shortage of local stocks is that of transportation. There is great scarcity of metal drums in which to pack materials, and tank cars also are in very poor supply. This renders the transfer of chemicals from the plant to the user difficult. Added to that, the current railroad men's strike has complicated matters. Plants whose products are sold up months ahead find themselves with an accumulation of manufactured product which they are unable to ship, and jobbers and consumers, even though fully covered by supply contracts, are unable to get goods. At present the rail strike seems to have spent the greater portion of its strength so far as the Chicago district is concerned.

Heavy Chemicals

With the exception of alkali products this market shows no changes of moment. *Formaldehyde,* while about as scarce as was the case when $1 a pound was being asked, is now going for 61@65c., with the latter figure probably most accurately reflecting the market. All *alcohols* remain in heavy demand at top prices. *Wood alcohol* is now higher than ever before, transactions being noted at $2.80@$3 for 97 per cent. *Ethyl alcohol,* 190 proof, is quoted nominally at $5.35@$5.50, practically none being available, and *denatured* can be purchased at a prevailing price of $1.

Caustic soda is very hard to get. A peculiar feature is that while the price in cars, f.o.b. works, is now 6¼c. on solid and 6½c. on granulated, what spot stocks are available may be purchased at from ⅛c. to ⅜c. lower. The reason is that dealers' stocks have been acquired on contract at considerably lower figures. Needless to say, only small quantities are available. *Soda ash* is daily becoming harder to get, as the plants are all far behind on orders. Current quotation of 3¼@3¾c. should be considered nominal. *Bleach,* suffering from a shortage of containers, is up on market to 4c. per lb. in carloads. Actual transactions in spots have gone as high as 4½c. *Sal soda,* though still scarce, has receded somewhat in price. Current quotations are $1.35 per cwt. from factory, $1.50 per cwt. from Chicago stocks.

Sodium nitrite shows a further return to normal, 25c. per lb. being the ruling quotation. Much interest is being shown in glycerine and a slight increase, to 25c. per lb., for c.p. grade is noted. *Blue vitriol* is also in good demand and has recently advanced ¼c., to 8¼@8½c. Acid stocks are getting low; however, no price changes of importance have occurred. Owing to increased costs, *acetic* is up slightly, 28 per cent commercial being quoted at $4.37½ per cwt. *Nitric* has also advanced a half cent, today's price on 38 deg. being 9½c.

Coal-Tar Products

Shortages of containers and transportation facilities tend to keep supply limited and prices strong. *Benzol,* with demand insistent, is up to 30c. in cars, while *toluol* still holds at the old price of 28c. *Aniline oil* remains at a premium, recently advancing to 36c. per lb. The *salts* are also advanced to 34c. and both oil and salts are very hard to obtain for immediate delivery. *Naphtha* is also scarce, and it is difficult to name definite quotations. Holders of stock are asking 26c. and even higher.

Vegetable Oils

An almost total lack of buying strength has caused further slump in vegetable oils. Supply is plentiful in all lines. *Cocoanut oil* is today being quoted at 16¼c. on the Coast in either tanks or barrels, and in barrels the local price is 17⅜c. *Corn oil,* with no buyers, is offered from stock at 15¼c. and in cars, f.o.b. works, at 14⅝@14⅝c. *Cottonseed oil* shares the general depression, the crude being worth 15⅜c. while prime summer yellow in sellers' tanks is offered at 16½c. No quotation is available on refined, deodorized, in barrels. *Soya bean oil* shows the greatest weakness of the entire list, with Coast quotation in tanks 13½c. and local stocks in barrels finding no takers at 15c.

Flotation Oils—Naval Stores

Entry of the new crop has so far influenced *turpentine* but slightly, ruling price now being $2.40 in bbl., $2.22@$2.25 in cars. It is freely admitted that this price is too high, and a break may be anticipated at any time. This market will probably see two-dollar turps in a short time. Flotation oils do not seem to know where to stop in the price climb; .933 pure steam distilled pine oil is up to $1.85 today and the destructively distilled grade is only 10c. cheaper, at $1.75. *Pine tar oil* and *rosin,* remaining in good demand, show no fluctuation.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.		$0.60 – $0.65
Acetone	lb.	$0.13 – $0.15	.16 – .18
Acid, acetic, 28 per cent	cwt.	3.50 – 4.00	4.25 – 4.50
Acetic, 56 per cent	cwt.	8.00 – 8.25	8.25 – 8.50
Acetic, glacial, 99½ per cent. (above)	cwt.	12.00 – 14.00	16.50 – 17.50
Boric, crystals	lb.	.14½ – .15½	.15½ – .16½
Boric, powder	lb.	.14½ – .15	.15 – .16
Citric	lb.	.85 – .85	1.17 – 1.18

Lead acetate, normal	lb.	.14 – .14½	.15 – .18
Lead arsenate (paste)	lb.	.11 – .12	.13 – .17
Lead nitrate, crystals	lb.	–	.90 – 1.00
Litharge	lb.	.14 – .15	.15½ – .16
Lithium carbonate	lb.		1.50
Magnesium carbonate, technical	lb.		.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	3.40 – 3.55	3.60 – 4.25
Magnesium sulphate, commercial	100 lb.	3.00 – 3.10	3.10 – 3.25
Nickel salt, double	lb.	.14 –	.15 –
Nickel salt, single	lb.	.16 – .17	.17½ –
Phosgene (see carbonyl chloride)		–	–
Phosphorus, red	lb.	–	.60 – .65
Phosphorus, yellow	lb.	–	.35 – .37
Potassium bichromate	lb.	.36 – .37	.38 – .42
Potassium bitartrate (cream of Tartar)	lb.	.56 – .58	.59 – .61
Potassium bromide, granular	lb.	–	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.21 – .25	.28 – .30
Potassium chlorate, crystals	lb.	.15 – .16	.21 –
Potassium hydroxide (caustic potash)	lb.	.28 – .29	.30 – .35
Potassium iodide	lb.	–	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 –
Potassium permanganate	lb.	–	$0.65 – $0.95
Potassium prussiate, red	lb.	1.00 – 1.05	1.10 – 1.2
Potassium prussiate, yellow	lb.	.34 – .36	.38 – .41
Potassium sulphate	ton	225.00 – 240.00	–
Rochelle salts (see sodium potas. tartrate)		–	–
Salammoniac (see ammonium chloride)		–	–
Salsoda (see sodium carbonate)		–	–
Salt cake	ton	22.00 – 26.00	–
Silver cyanide (nominal)	oz.		1.25 –
Silver nitrate (nominal)	oz.		.77 – .82½
Soda ash, light	100 lb.	2.75 –	3.50 – 3.60
Soda ash, dense	100 lb.	2.80 – 3.25	3.55 – 3.65
Sodium acetate	lb.	.06 – .07	.07 – .08
Sodium bicarbonate	100 lb.	2.55 – 2.60	2.75 – 3.00
Sodium bichromate	lb.	.33 – .34	.35 – .40
Sodium bisulphate (nitre cake)	ton	7.00 – 7.50	8.00 – 10.00
Sodium bisulphite Powered	lb.	.06½ – .06½	.07 – .17½
Sodium borate (borax)	lb.	.08 – .08½	.09 – .09½
Sodium carbonate (sal soda)	100 lb.	1.60 – 1.80	1.80 – 2.00
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.24 – .25	.26 – .27
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	4.50 – 5.50	6.00 – 6.50
Sodium hyposulphite	lb.	–	.03 – .04
Sodium metabisulphite	lb.	.2.50 –	3.25½ –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.26 – .27	.33 – .35
Sodium peroxide, powdered	lb.	–	.30 – .32
Sodium phosphate, dibasic	lb.	.03½ – .04½	.04½ – .05
Sodium potassium tartrate (Rochelle salts)	lb.	.39 – .40	.40 – .41
Sodium prussiate, yellow	lb.	.23 – .27	.30 – .40
Sodium silicate, solution (40 deg.)	lb.	.01½ – .02	.02 – .02½
Sodium silicate, solution (60 deg.)	lb.	.02½ – .03	.04 – .05
Sodium sulphate, crystals (Glauber's salt)	cwt.	1.50 – 1.70	1.75 – 2.00
Sodium sulphide, crystal, 60–62 per cent (conc)	lb.	.07 – .07½	.08 – .08½
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05½ –	.06 –
Sulphur, crude	ton	22.00 –	–
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –	.46 – .50
Tin oxide	lb.	.50 – .60	.65 –
Zinc carbonate, precipitate	lb.	–	.19 – .20
Zinc chloride, gran.	lb.	.13 –	.13½ – .15
Zinc cyanide	lb.	.49 –	.50 – .60
Zinc dust	lb.	.11½ – .12½	.13 – .15
Zinc oxide, U. S. P.	lb.	–	.19 – .21
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 — $1.10
Alpha naphthol, refined	lb.	1.40 — 1.60
Alpha naphthylamine	lb.	.40 — .50
Aniline oil, drums extra	lb.	.34 — .45
Aniline salts	lb.	.42 — .48
Anthracine, 80% in drums (100 lb.)	lb.	.90 — 1.00
Benzaldehyde (free)	lb.	2.00 — 2.10
Benzidine, base	lb.	1.25 — 1.35
Benzidine, sulphate	lb.	1.20 — 1.25
Benzoic acid, U. S. P.	lb.	.90 — 1.10
Benzoate of soda, U. S. P.	lb.	.80 — 1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 — .36
Benzol, 90%, in drums (100 lb.)	gal.	.25 — .31
Benzyl chloride, 95-97%, refined	lb.	.35 — .40
Benzyl chloride, tech.	lb.	.25 — .35
Beta naphthol benzoate	lb.	.50 — .65
Beta naphthol, sublimed	lb.	.70 — .90
Beta naphthol, tech.	lb.	.45 — .55
Beta naphthylamine, sublimed	lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 — 1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85 — 1.00
Cresylic acid, 50%, first quality, drums	gal.	.60 — .70
Dichlorbenzol	lb.	.08 — .10
Diethylaniline	lb.	1.40 — 1.50
Dimethylaniline (nominal)	lb.	—
Dinitrobenzol	lb.	.30 — .37
Dinitrochlorbenzol	lb.	.25 — .30
Dinitronaphthaline	lb.	.45 — .55
Dinitrophenol	lb.	.34 — .36
Dinitrotoluol	lb.	.40 — .45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 — .40
Diphenylamine (nominal)	lb.	.55 — .65
H-acid (100 lb.)	lb.	1.90 — 2.00
Metaphenylenediamine	lb.	1.15 — 1.80
Monochlorbenzol	lb.	.10 — .12
Monoethylaniline	lb.	1.70 — 1.85
Naphthalene, crushed, in bbls. (250 lb.)	lb.	.08 — .09
Naphthalene, flake	lb.	.09 — .10
Naphthalene, balls	lb.	.10 — .11
Naphthionic acid, crude	lb.	.70 — .85
Nitrobenzol	lb.	.14 — .19
Nitronaphthaline	lb.	.41 — .50
Nitrotoluol	lb.	.30 — .36
Orthoamidophenol	lb.	3.75 — 4.25
Orthodichlorbenzol	lb.	.15 — .20
Orthonitrochlorbenzol	lb.	.81 — 1.25
Orthonitrotoluol	lb.	.35 — .40
Orthotoluidine	lb.	.35 — .45
Paraamidophenol, base	lb.	2.50 — 3.50
Paraamidophenol, HCl	lb.	2.50 — 3.25
Parachlorbenzol	lb.	.08 — .12
Paranitraniline	lb.	1.00 — 1.35
Paranitrotoluol	lb.	.45 — .50
Paraphenylenediamine	lb.	3.00 — 3.50
Paratoluidine	lb.	2.00 — 2.50
Phthalic anhydrid	lb.	.65 — .75
Phenol, U. S. P., drums extra (240 lb.)	lb.	.23 — .25
Pyridin	gal.	2.25 — 2.50
Resorcin, technical	lb.	4.25 — 4.50
Resorcin, pure	lb.	6.25 — 6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.50 — .52
Salicylic acid, U. S. P.	lb.	.55 — .60
Toluol	lb.	.90 — 1.00

Solvent naphtha, water-white, in drums, 100 gal.	gal	$0.5 —	$0.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.38 —	$0.39
Beeswax, refined, light	lb.	.40 —	.41
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	.80 —	.88
Carnauba, No. 2, regular (nominal)	lb.	.60 —	.70
Carnauba, No. 3, North Country (nominal) †	lb.	.43 —	.45
Japan	lb.	.19 —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	..... —	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.11
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.11 —	.11½
Paraffine waxes, refined, 133-135 m.p.	lb.	.12 —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.13½ —	.14
Stearic acid, single pressed	lb.	.26 —	.27
Stearic acid, double pressed	lb.	.32 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist.	gal.	.....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.38
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.95	—$19.50
Rosin E-I	280 lb.	19.75	— 20.00
Rosin K-N	280 lb.	20.25	— 21.95
Rosin W. G.-W. W.	280 lb.	22.00	— 24.00
Wood rosin, bbl.	280 lb.	15.50	— 18.50
Spirits of turpentine	gal.	.....	— 2.49
Wood turpentine, steam dist.	gal.	2.35	— 2.40
Wood turpentine, dest. dist.	gal.	.....	— 2.00
Pine tar pitch, bbl.	200 lb.	8.40	— 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	— 15.00
Retort tar, bbl.	500 lb.	15.00	— 15.50
Rosin oil, first run	gal.	.92	— .95

BINGHAM (Bingham Canyon P. O.)—The Utah Consolidated Mining Co. plans to build a mill to concentrate copper ores by flotation with a capacity of 1,000 tons. The company is in the market for flotation machinery. Estimated cost, $75,000.

Vermont

ST. JOHNSBURY — The Cary Maple Sugar Co. has awarded the contract for the construction of a 2- and 4-story, 54 x 200-ft. factory, to the H. P. Cummings Constr. Co., Fidelity Bldg., Portland, Me. Estimated cost, $125,000. Noted Jan. 21.

Virginia

CULPEPER—The town has awarded the contract for the construction of a waterworks system, to Diehl & Vance, archts. and consult. engrs., Virginia Carolina Bldg., Norfolk. Contract for the construction of small filter plant including coagulating basin, etc., will be sublet.

Wisconsin

BURLINGTON—The Burlington Brass Wks. will build a 1-story, 100 x 140-ft. foundry. Work will be done by day labor. Noted March 23.

MILWAUKEE—The Natl. Brake & Electric Co., Belleview Place, is having plans prepared for the construction of a 1-story, 160 x 180-ft. addition to its foundry. Estimated cost, $150,000. H. J. Esser, Camp Bldg., archt. and engr.

ROBERTS—The Bd. Educ. is having plans prepared for the construction of an addition to the high school, here. A small chemical laboratory will probably be installed in same. Estimated cost, $50,000. Alfred H. Wheeler, 410 Globe Bldg., St. Paul, Minn., archt.

SHEBOYGAN FALLS—C. S. Weisse Co., c/o L. A. Weisse, had plans prepared for the construction of a 4-and 6-story, 60 x 250-ft. tannery on Buffalo St. Estimated cost, from $100,000 to $150,000.

VIROQUA—Edward J. Older, city clk., will receive bids until April 29 for the construction of 2 sewage disposal plants consisting of tanks, sprinkling filters, etc.

Ontario

KITCHENER—The Long Tanning Co., Francis St., has awarded the general contract for the construction of a 3-story tannery to Casper Braum, King and Water Sts. Estimated cost, $150,000.

TORONTO—The Canadian Natl. Carbon Co., 265 Adelaide St., W., and the Prest-o-Lite Co., of Canada, Ltd., 120 Elm St., are having plans prepared for the construction of a 2- and 3-story, 80 x 400-ft. and a 2-story, 80 x 400-ft. factory buildings at Hillcrest Park. Equipment for making dry cells, batteries, acetylene, etc., will be installed in same. Estimated cost, $450,000.

TORONTO—The Y.M.C.A., 21 McGill St., and the Dominion Council, 604 Jarvis St., plan to construct a 4-story Y.M.C.A. building. Chlorinating and violet ray equipment for the swimming tank will be installed in same. Estimated cost, $650,000.

Quebec

CHELSEA—The Royal Securities Corp., Ltd., 164 St. James St., Montreal, plans to build a pulp and paper mill on the banks of the Gatineau River, near here. Estimated cost, $1,000,000.

Saskatchewan

SASKATOON—The North Star Oil Refining Co. will soon receive bids for the construction of a refinery. A warehouse and tanks will be constructed in connection with same.

MOOSE JAW—The Western Oil Co., Ltd., will soon receive bids for the construction of a large oil refining plant.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its sixth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN WELDING SOCIETY will hold its annual meeting at the Engineering Societies Building, 33 West 39th St., New York, on Thursday, April 22.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHAMBER OF COMMERCE OF THE U. S. announces that its eighth annual meeting will be held at Atlantic City, April 27 to 29, the subject of which will be "Increased Production."

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK is pleased to announce the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theater: "Water Supply and Drainage in Water Cantonments," Wednesday, April 21, at 4 p.m., Prof. D. D. Jackson, administrative head, department of chemical engineering, Columbia University (*Lantern*); "Modern Coke and Gas Manufacture" (Koppers process), Thursday, April 29, at 4 p.m., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 p.m., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 p.m., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E., will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MINE INSPECTORS' INSTITUTE OF AMERICA will hold a meeting at Cleveland, Ohio, July 13, 14 and 15.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5 which will be held in Glace Bay.

THE NATIONAL ACADEMY OF SCIENCES will hold a meeting at the Smithsonian Institution and the new museum, Washington, D. C., April 26 to 28, at which there will be discussions and reports on timely subjects of general interest. All scientific sessions will be open to the public.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE NATIONAL SAFETY COUNCIL, Engineering Section, will hold its spring conference in the Engineering Societies Building, New York City, on April 27.

THE NEW JERSEY CHEMICAL SOCIETY plans the following: Saturday, April 24, 2:30 p.m., visit to the plant of the Raritan Copper Co., Perth Amboy, N. J.; Monday evening, May 10, regular meeting; Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J., regular meeting and ladies' day.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

Lessons from the Last A. C. S. Meeting

THE American Chemical Society is big; it has now over 15,000 members. Its meetings are so well attended that the problem of hotel accommodation becomes difficult even in the greatest cities. The same holds true in regard to convenient railway accommodations. The number and variety of papers read are no less than bewildering. At the St. Louis meeting last week there were 266 papers on the program, and if we were to include the additional addresses brought out in the discussions which followed these presentations the number would be materially increased.

Immensity of this sort brings certain inconveniences in its train. The allotment of papers to the various sections is sometimes a difficult matter and the lack of publication of the papers or even of abstracts of them before the meeting makes it hard for a member or visitor to determine which he will hear. Titles are occasionally misleading.

And yet proposals for changes in procedure meet with objections which are at once sincere and worthy of consideration. The thing most needed, in our opinion, is that a short abstract of each paper be printed under its title in the program. Secretary PARSONS says this would be possible provided a hard and fast rule were made to the effect that no paper be admitted unless a digest of not over a certain number of words were forwarded to him by the author before a given date. The provision of exceptions to the rule would make it of no effect because authors, as a general rule, will not abstract their own papers if they can avoid it; and again, authors are seldom good abstractors of their own works. We understand that such a rule exists in the American Institute of Chemical Engineers, but we also understand that even in this comparatively small organization it is the secretary who really does the work. To abstract 266 papers on such a variety of subjects would require a whole congregation rather than one or more Parsons!

The question is raised whether the number of papers is not too great. Many would be better printed than read and in such a form they would be more useful. But at least 75 per cent of those presented will never see the light of print and this is the only chance that anyone but the author will ever get to see them. The mere record of such contributions on the programs is of great value, for it tells by whom research is in progress. We think it would add to the value of the record if the academic or technical occupation of each author were also given as well as his address. If we had our way about it, we should insist on the requirement that every author furnish an abstract of his work presented. In the end it would be of marked value to the contributors.

The unanswerable argument in favor of the large number of papers is also made that it is wholesome to invite chemists to tell of what they are doing. Every effort should be made to encourage this. We have been especially impressed at this meeting with the frank contributions from the laboratories of industrial establishments which are engaged in lively competition. We have not reached full measure in this respect as yet—or anything like it—but the tendency is growing among their scientific men. As mentioned elsewhere, it has been proposed that the general meetings of the Society be restricted to one instead of two each year. Along with this it is suggested that sections in neighboring states have joint meetings one or more times in the interim. The convenience of this is offset by the possibility that such a procedure might make for sectionalism, which is to be avoided at all hazards, and again, especially in regard to industrial chemistry, it is important that those engaged in it get a chance to exchange views with their colleagues from all over the country.

We wish it were possible for a larger number of professors of chemistry to attend these meetings. During a short visit to the dye section on Wednesday morning there were discussed and elucidated the following subjects: The application of certain dyes for photographic sensitizing. This comparatively new subject is pregnant with possibilities. Its great use, of course, has been in army air work, but owing to the much clearer delineation which certain dyes provide, it promises much in the field of astronomy as well. New tests for the purity of intermediates were proposed, the merits of formic acid in the dyeing industry were presented and the reasons why, and an illuminating presentation of the action of synthetic dyes in chemicotherapy was given. We believe that young men should be taught chemistry as a thing of today and alive rather than as a thing to be groaned out of text books and boned over. These meetings emphasize the vitality of the subject.

The sections continue to multiply. The dye section is growing strong, the rubber division is finding itself, the leather chemistry section is started and it deserves to succeed. Leather manufacturers have been singularly backward in furthering the science of tanning—with notable exceptions—and we understand there are still a number of influential old leatherbacks who feel that it is a great mistake to wander away from the regular leather association. Of course there is the danger that they may get some new notions and come back talking about colloid chemistry! In fact, one of the leading leather chemists read a paper at the Colloid Symposium on "Vegetable Tanning as a Colloid Chemical Process." To the good old practical tanner who thanks GOD that he is not a theorist such a title must sound like the hissing of a snake. The division of industrial and engineering chemistry is almost overburdened with variety. The few isolated papers on

metallurgy seem almost lost in the shuffle and it seems fair to question whether the subject of metallurgy is properly within the domain of the Society or not. The successful Symposium on Cellulose Chemistry has led to the proposal that a cellulose section be organized, and we expect to see the plan mature.

The St. Louis meeting was successful.

Extrusion Or Diffusion?

SINCE Messrs. RAWDON and SCOTT have given considerable attention, in their paper on the Microstructure of Iron and Mild Steel at High Temperatures, reprinted on page 787 of this issue, to Dr. HOWE'S ideas regarding the expulsion of excess insoluble constituent to the boundaries of austenite grains, a brief consideration of this theory may be interesting. In his recent book on "The Metallography of Steel and Cast Iron," he cites the various following facts to support his proposed mechanicalized transport of exotics, which might be described as an "elbowing" effect:

First, those constituents appearing as needles in Widmanstättian bands are in that arrangement due to an expulsion to the octahedral cleavages of austenite rather than to an inherent crystallinity of the cementite or ferrite itself. The former is described as being orthorhombic, assuming the form of a rhombohedron, while OSMOND and CARTAUD find sublimed crystals of both α and β iron to be cubic.

Second, excess constituent will be found at the former location of slip bands after annealing overstrained metal.

Third, slag particles are at boundaries because crystals of austenite growing from a mother liquor *push* them away.

Fourth, since slag is posited by "elbowing," its later frequent accompaniment of ferrite (or cementite) borders is caused by a like action.

Fifth, ferrite (or cementite) is *extruded* to the borders of austenite crystals upon cooling through the critical range, thus forming the well-known network shown in microphotographs.

Sixth, excess constituent is by the same action extruded to all exposed surfaces, whether outer skin or inner cavities.

Presumably Dr. HOWE would be quite willing to admit that there is another way to explain the migration of excess constituent, rather than by an elbowing effect; all of these reasons of his, with the exception possibly of the last, might be well explained otherwise. In other words, one alternative hypothesis is that excess constituent migrates to preformed nuclei of the same substance, much as a crystal grows in aqueous solution. The movement of substances through solution (solid or liquid) is matter of diffusion to maintain equilibrium; that is, continual dissolution at one place of low concentration and redeposition in another place at higher concentration rather than a mechanical transportation of the substance *en masse*.

His statement that internal cavities are lined by ferrite in hypo-eutectoid and cementite hyper-eutectoid steels is rather a poser to one who does not accept his idea of elbowing effect. RAWDON and SCOTT'S experiments showing a pronounced decarbonization when heating either grade of steel *in vacuo*, leave one somewhat bewildered by the imposing evidence cited by Dr. HOWE showing migration of cementite to superfices during heating. On the other hand, the proponent of diffusion might ask him to cite some instance where austenite has been able to transport, bodily, a slag inclusion, or some *insoluble* constituent. Certainly the grain boundaries in Figs. 1, 2, 3, 6 and 8 appear to be entirely independent of the black spots, presuming them to represent non-metallic inclusions. If austenite will elbow out cementite or ferrite, as the case may be, it certainly ought to elbow out a particle of sulphide or any other foreign matter that might be there. On the other hand, diffusion is powerless to move an insoluble substance. So that the real test of the problem would be to discover some sample wherein an insoluble constituent has been moved.

Instances of this sort are possibly totally lacking in published literature. Dr. GIOLOTTI remarked that unpublished researches prove to his own satisfaction that slag is not moved after heat treatment. Dr. STEAD has written, in describing some of his experiments on the diffusion of phosphorus, that after long-time annealing he was able to break up all dendritic structure and to equalize phosphorus throughout the metal, but he states explicitly that even then non-metallic inclusions were not changed in location.

The Greater Circulation of Chemists

EVERY spring and fall a thousand or so American chemists, representing the widest range of interests and thought, have shown their professional spirit by setting aside their normal activities for a week and attending the semi-annual meetings of the American Chemical Society. About one-fourth of this thousand have manuscripts, giving the findings of their laboratories, which they are scheduled to talk over hurriedly in a time allowance varying usually but little from ten minutes. It would be superficial to conclude that the motive of the remaining three-fourths in making the journey to the convention city was primarily a desire to listen to the other fourth, especially when it is considered that those of the papers presented that are considered important will soon be published.

It might be thought that papers of insufficient consequence to deserve space in the journals should be barred from taking up the precious minutes of the meeting. This would be consented to without argument, were it not for the fact that many points are brought out in the discussions which prove to have great value and would never have been brought to wide attention if it had not been for the suggestion found in some minor-grade paper. However, it is in this very important aspect that the treatment of papers presented before the American Chemical Society is lamentably weak. Discussions are not fostered by giving counter-opinion time to formulate and be presented. Practically no provision is made for light on the other side in the papers published and it is left to each individual reader to furnish his own salt by way of condiment with what he feeds his brain.

It may be said that to a limited extent, after the sessions close, the congregations in the lobby, halls, dining rooms, take up in their conversation an interchange of opinion on papers just delivered along with all sorts of other topics of interest to chemists. It is this phase of the meeting that has the greatest value

and more than repays for all expenditure of time and money for personal attendance. The acquaintance, the critical opinions, the ideas that everyone gains or should gain from such a congregation of the highest chemical talent is of the greatest value. It is not the attendance of the meeting as a programmed performance that counts, but the greater circulation of chemists in their own channels.

The precedent set by the Harvard Graduate Chemists Association in scheduling a luncheon on the Tuesday of each meeting week was immediately followed by the alumni of Chicago, M.I.T., and Pennsylvania. This will be very beneficial as well as enjoyable. It will give the alumni chemists an opportunity to get acquainted with those who preceeded or followed them in the old labs at their alma mater.

Byproduct Coke Passes Beehive

AMONG the things for which the year 1919, now happily passed into memory if not into happy memory, will be remembered is that in that year the output of byproduct coke in the United States first exceeded the output of beehive coke, the preliminary figures of the United States Geological Survey, just issued, showing production of 25,171,000 net tons of byproduct coke and 19,650,000 tons of beehive coke, making a total of 44,821,000 net tons, the proportions being 56 per cent byproduct and 44 per cent beehive.

In one sense the passing of beehive coke by byproduct coke in 1919 was a lame performance, in that the byproduct output, while exceeding the beehive product of 1919, fell far short of equaling the beehive output in numerous preceding years. The beehive record is 35,364,224 tons produced in 1916. From another viewpoint the performance was particularly creditable, for 1919 was a year of light demand for coke, and byproduct coke showed its stamina by declining only 3 per cent in tonnage from 1918, when beehive production slumped off by 36 per cent.

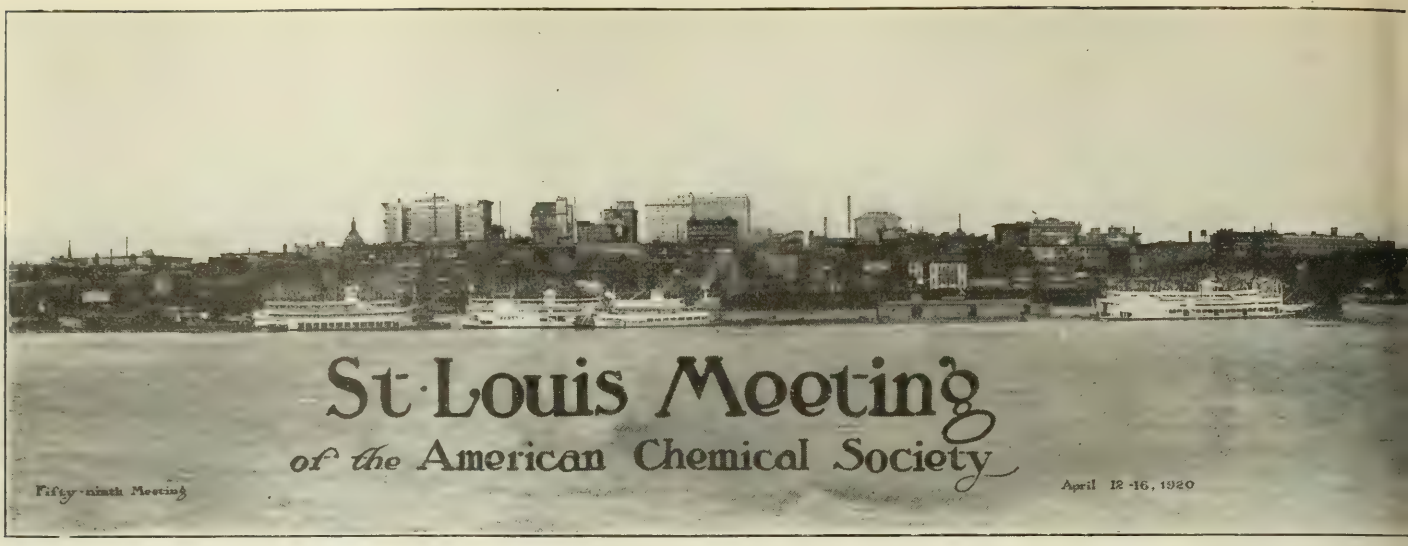
Whether the rise in byproduct coke manufacture in the United States should be considered slow or fast depends on the viewpoint. It has been fast considering that the present capacity is double the capacity of five years ago and more than quadruple the capacity of ten years ago. On the other hand, the merits of the byproduct process were being preached in vain more than a quarter century ago, although the arguments were backed up by some substantial figures drawn from experience abroad.

It is safe to say, at any rate, that byproduct oven building was backward for a time and then was quite in the forefront. This is what would naturally be expected, for the burden of doing the thing rested very largely upon the iron and steel industry, seeing that in smelting its ores that industry consumes 80 per cent or more of the coke produced in the country. Now, the iron and steel industry is one that has grown rapidly in tonnage, requiring constant reinvestment of its profits, and it has also had occasion to make many improvements in methods and appliances, this also requiring much capital. Accordingly the industry has always had occasion to invest more money than it had, and something had to wait. The industry is highly competitive, in that while all may sell at much the same price—the present exception is a good test of the general rule—the concern that lags behind others in making improvements is likely to get lost. Hence when byproduct coke oven building eventually became "the thing" the work was prosecuted rapidly. It was not until 1900 that byproduct coke production crossed the million ton mark, while in 1907 it crossed the five million ton mark. In 1912 more than 10,000,000 tons was produced, while in 1917 more than 20,000,000 tons was made—22,439,280 tons, to be precise. Last year's production, as noted above, was about 25,171,000 tons, and the Geological Survey estimates the capacity, at full rating for each plant, at 39,500,000 tons at the beginning of the present year. Assuming that 85 per cent of rating is a fair expectation of actual output, this makes the real capacity rating at the beginning of this year about 33,600,000 tons. Plants being built should raise this to 36,800,000 tons.

Nearly all the byproduct coke made is used in the iron blast furnace, only limited tonnages going to the foundry and for miscellaneous uses. The blast-furnace requirements may be estimated approximately. The coke furnaces may be taken at about 45,000,000 gross tons of pig iron a year. The coke consumption per ton of pig iron has been reported for a number of years, decreasing to 2,252 pounds per ton in 1915 and then increasing thereafter, chiefly, it appeared, on account of coke turning to poor quality during the war. On account of its regularity, byproduct coke shows somewhat better performance than beehive coke, and 2,200 pounds is a conservative estimate for future performance. This would mean 49,500,000 tons of coke to operate all the coke blast furnaces, and of this the byproduct ovens could furnish, according to the estimate, 36,800,000 tons, or 74 per cent. Considering simply the total coke, and taking blast-furnace consumption as 81 per cent of the total consumption, the entire coke requirements would be 61,000,000 tons, with, say, 37,000,000 tons byproduct and 24,000,000 tons beehive, the proportion being 60 per cent and 40 per cent. This leaves quite a field still for the beehive coke oven, even though there would be a 32 per cent decrease from the 35,464,224-ton record made in 1916.

Cogitations on Colloidal Theories

THE colloid symposium held at the meeting of the American Chemical Society in St. Louis brought forth several statements which give food for contemplation to even those who are uninitiated in the mysteries of the general nature of colloids. It seems that the ideal of the soap chemist is to obtain a bar of water that would stand alone. MARTIN H. FISCHER says that he likes ions, but there are not an awful lot of them around. A discovery by JOHN ARTHUR WILSON that the standard methods of tannin analyses approved by the American and European leather chemists' associations were found to give results which in scientific practice were from 50 to 250 per cent out of the way was as startling as it is true. We expect to hear from makers of various extracts that Mr. WILSON'S conclusions are soused and tanned with error; but against this is the fact that he has put them into practice and they work. With a start like that made by Mr. WILSON it will be a grand thing all around if American tanners in general take a hitch in their belts and go in quest of greater scientific control. Truly the research and application of colloid chemistry is to bear an even greater economic influence on the chemically controlled industries.



Report of the Events of the Convention—Review of a Selection of Addresses, of the General Meetings and Divisions of Industrial Chemists and Chemical Engineers, Sugar, Leather, Dyes, Physical and Inorganic Chemistry

THE fifty-ninth meeting of the American Chemical Society was held in St. Louis, April 12 to 16, inclusive. About 1,000 members attended in spite of the interference brought to transportation by the railway operators' strike. The program contained 266 papers, of which notes from some of the more important are presented in this report. The description of the industrial excursions and the report on the rubber section could not be included in this issue, but will be published later.

The General Meeting

The general meeting of the Society was held at Hotel Statler at 10 o'clock on April 11. The Hon. HENRY W. KIEL, Mayor of St. Louis, made the address of welcome, to which response was made by President NOYES. Dr. ERNEST SOLVAY of Brussels was then elected to honorary membership in the Society and memorial resolutions on the death of Prof. ALFRED WERNER of Zurich, also an honorary member, were presented and adopted. The Hon. E. P. COSTIGAN of the U. S. Tariff Commission was scheduled to speak on "The Chemical Industry and Legislation," but duties at Washington prevented him from attending. In his place PAUL BROWN, editor of *America at Work* of St. Louis, spoke on "The Physical Basis for the Economic Development of the Mississippi Valley."

Mr. Brown proved an able speaker and the only possible conclusion to draw from his remarks is that St. Louis is the navel of the world. He said that the Mississippi River was now under control and that the tendency of future traffic will be from north to south instead of from west to east, on the ground that there is a greater variety of products by longitude than by latitude. The use of the great river is only beginning. He observed that the North has a great lesson to learn from the South in the community spirit in farming which has developed there, while Northern farming has tended to encourage individualism. He noted also that the center of population of the United States, which is but 125 miles from St. Louis, is also the center of the production of raw commodities.

The second general address was by Dr. CHARLES H. HERTY, editor of the Society's *Journal of Industrial and Engineering Chemistry*, on "Victory and Its Responsibilities." Dr. Herty was in great form. He said that five years ago we chemists lamented the fact that we could not get a hearing. Newspapers paid no heed to our warnings or recommendations. Today the chemist has come into his own. Then he told what the Society had done to bring this about, of the development and work of its publicity bureau, commended certain books on popular chemistry that made one of the editors of CHEMICAL & METALLURGICAL ENGINEERING blush, and declared that clippings from newspapers today in regard to chemical news are generally correct and readable.

He referred to five public measures that affect the chemist in his work, some of which are still pending. These were respectively the Longworth, Bacharach, Nolan and Army reorganization bills and prohibition. At the mention of the last measure it seemed as though sympathy with the speaker was beginning to wane, but the only point that he brought out was the improvement of present over former regulations in regard to the choice of denaturants for alcohol. In regard to the Longworth bill, he said he never saw greater consternation than that depicted on the countenances of two leaders in the dye industry in Germany when they read in the Frankfurter *Zeitung* that it had passed the Senate.

The Nolan bill for increasing the facilities and appropriations for the Patent Office passed the Congress with but one dissenting vote. That would have been impossible a few years ago.

The Bacharach bill, which does away with duty-free apparatus for institutions of learning, is another feature of leading importance. If we train our young chemists to use foreign-made apparatus, glassware, porcelain, balances or the like, what chance will American-made apparatus have with them when they start out to work?

Everybody except the highest authorities in the War Department seemed to recognize the value of chemistry in warfare and fortunately, despite opposition, the Congress has seen fit to insist upon its continuation as a separate branch of the service. It is the obligation of

the chemists of America to give this department of the army our loyal and earnest support.

The National Exposition of Chemical Industries has been a great help in putting chemistry upon the map. And the authorized capital of chemical corporations within the past five years is nearly five hundred million dollars, while during the first three months of the current year new companies with capital of over sixty million dollars have been authorized.

Grave Responsibilities of Chemists

In view of these developments, chemists have grave responsibilities. They must be fearless and original. And they must provide for education. This is not a rosy side today. It is too much to ask men to remain as professors unless they can live on their salaries while industry offers so much richer rewards.

And again, if two such institutions as Cornell University and the Massachusetts Institute of Technology offer all the facilities of their staffs and laboratories to the War Department, and the Department, with a war before it, declares it has no need of chemical enlightenment or aid—which happened three years ago—there is something wrong. The error was corrected after expensive delay, but the question arises whether we are not to blame if such misconceptions of chemistry exist in high places. Since the armistice it has been proposed by the War Department itself that we build a $20,000,000 institution and provide for the complete chemistry of warfare by sending West Point graduates there who have had fourteen weeks in chemistry and giving them another year at it! Something wrong there, too. The fact is, Dr. Herty said, we haven't yet taught our people what chemistry means and we must do it. He quoted Prof. Duisberg of the Bayer Co., who said: "They will make a hard treaty for us, and we must accept. You beat us in production in this war, but we will beat you in production in the next war." And he brought out a record of German military plans to send over a dirigible airship 775 ft. long to drop five tons of poison gas on New York on Thanksgiving in 1918.

It was, in fact, a very lively speech.

Council Meeting

The meeting of the Council began at 4 p.m. at the University Club, but in response to the request of about thirty members who were delayed by the railway strike, all transactions were made subject to revision after their arrival at the evening session, which convened at 9:15. Members of the Council who were present were guests of the St. Louis Section at dinner during recess, at which about 100 councilors in all were present. It was resolved to hold the 1921 spring meeting at Rochester and the 1920 fall meeting during the second week in September at Chicago. There exists a tentative understanding between the American Chemical Society and the American Association for the Advancement of Science to hold the fall or winter meeting if possible jointly during convocation week once in four years if this should be possible, but the Chicago Section advised against it on the ground that it would be very difficult to secure proper hotel accommodations for members of both of these great bodies at the same time. It was recommended that the local sections in the neighborhood of Chicago join in a special meeting with Section C of the Association during convocation week (between Christmas and New Years) if such arrangement can be made. The request of the Pittsburgh Section to hold the fall meeting of 1921 in that city was held for consideration.

New sections were established at Denver, Col.; College Point, N. J.; Omaha, Neb., and Savannah, Ga. Mr. A. V. H. Mory of Cincinnati was elected councilor at large to fill the vacancy caused by the election of Dr. W. A. Noyes to the presidency.

It was also voted that nomination blanks sent by the secretary to local sections for nominations for the presidency shall include also blanks for nominations of councilors at large. Also that the Society unite with other associations in the formation of a standard metric system council. Drs. Alsberg, Bancroft and Derrick were re-elected representatives of the Society as members of the National Research Council. A committee of three was appointed to look into the question of preventing platinum thefts. Co-operation with the American Ceramic Society was determined upon. The heads of the divisions of abstracts were requested to co-operate with the British committee in preparing annual reports of the progress of chemistry in their respective branches.

A committee was appointed to look into and propose measures to remedy the present bad condition in institutions of higher learning in regard to the scarcity of instructors of chemistry and the inadequate salaries offered to them.

The question as to whether abstracts of all papers

presented shall be required to be sent to the secretary within a reasonable time before each meeting as a requirement to their inclusion in the program was tabled and a motion to hold meetings annually instead of semi-annually was made a leading subject for discussion and decision at the next meeting of the Council in September.

PASSAGE OF LONGWORTH BILL URGED

The following motion presented by Dr. HERTY was unanimously carried:

> The American Chemical Society, through its representative Council, urges upon our Senators the necessity of prompt passage of the Longworth bill in the form reported by the Senate Finance Committee. Under the absolute protection afforded by the blockade of German ports and encouraged by the favorable legislation of the preceding Congress, the coal-tar chemical industry has grown by leaps and bounds. But to meet the unusual competition threatened from the present unified German industry, far greater safeguards must be established than were formerly considered necessary. The delay in enacting such legislation has caused the withholding of large amounts of capital and the creation of an atmosphere demoralizing to research and to the technical development of the industry. We feel that the fate of this industry lies now with the United States Senate, and we urge the enactment of the bill as originally reported to the Senate by its Finance Committee, convinced that this legislative support will speed the industry's complete development, thereby assuring American consuming interests freedom from outside domination and providing a powerful factor in national defense.

The Smoker

The smoker was held in the great hall of the Liederkranz Club on Tuesday evening. There were about a thousand persons present and the St. Louis Section provided an elaborate musical and dramatic entertainment, an excellent collation and a frothy, sparkling beverage from the great brewery at St. Louis that looked and tasted like beer, but wasn't. As some one said: "It was beer all the way down to the necktie; after that it wasn't." Some good topical songs were provided of which we might quote some verses, but won't!

The Banquet

The banquet was held at Hotel Statler and was largely attended by prominent citizens of St. Louis as well as by members of the Society. A. C. BOYLSTON, plant manager of the Mallinckrodt Works, presided as toastmaster. FRANK CARTER, of the St. Louis bar and president of the Chamber of Commerce, spoke of the growth of chemical industry and emphasized the importance of its position in relation to the development of agriculture as well as other activities in national well-being. Dr. FREDERIC A. HALL, chancellor of Washington University, urged a closer union between neighboring chemical establishments and the research facilities offered by the university over which he presides. He concluded with an appeal to chemists to bear in mind the great responsibilities which are theirs and cautioned them lest they neglect the spiritual aspect of life, which is the business of every man.

Dr. WILLIAM A. NOYES, president of the Society, followed with an outline of the growth of chemistry in America and emphasized the obligations of chemists to the general welfare. Dr. L. V. REDMAN, of Chicago, spoke for his section and offered felicitations to that of St. Louis. Dr. CHARLES L. REESE, chief of the department of research of the du Pont company, made a strong plea for the humanities as a preliminary requirement for the study of chemistry. He also urged better support of the teachers of chemistry on the ground that if we do not see to it that their opportunities and living conditions are improved, chemistry will cease to perform its function in this country. He declared that industry can neither prosper nor even hold its own unless teaching is made attractive to the best type of men.

AMERICAN CHEMICAL SOCIETY IN GENERAL SESSION IN ST. LOUIS

Dr. RALPH H. MCKEE, professor of chemistry at Columbia University, announced that he was born in Missouri and related some illuminating experiences. ELLWOOD HENDRICK, consulting editor of CHEMICAL & METALLURGICAL ENGINEERING, after a humorous introduction, replied to the appeal of Chancellor Hall with the suggestion that a broader and more general understanding of chemistry might aid in the development of spiritual life. He pointed out that the popular concept of astronomic magnitudes and of geologic ages had magnified the idea of deity until it ceased to be within the range of human understanding, and that this has destroyed the feeling of nearness and familiarity. It crippled the sense of things unseen by brushing their presence away from the earth. Chemistry, on the other hand, has to do with particles, powers and forces, amazingly minute. The study of it teaches us that the road to infinity leads in both directions; and with this in mind we might better attune our ears to the Still Small Voice amid the Silences. Dr. CHARLES C. CASPARI, chairman of the St. Louis Section, told of his experiences in planning for the meeting and made his acknowledgments to his associates in the work.

A subject that was not mentioned at the banquet but which may as well be recorded here is the debt of the New York members of the Society to HERBERT G. SIDEBOTTOM, of The Barrett Co., secretary of the local section, who provided railway accommodations and generally looked after their comfort and convenience with rare kindness, diligence and efficiency.

Physical and Inorganic Chemistry

PREDICTION OF SOLUBILITY

J. H. HILDEBRAND gave the present status of his work on solubility with corrections on his solute-solvent tables. The great importance of the problem of solubility has been recognized ever since the days when the first alchemists sought a universal solvent. It is true that we have become somewhat less ambitious, or perhaps somewhat wiser, because we realize not only the unlikelihood of success in such a quest, but also the difficulty, which seems not to have occurred to the alchemists, of finding a container in which one could keep a universal solvent. But the chemist still works largely with solutions. His methods of analysis depend almost wholly upon precipitation and resolution and his education consists, to a very large extent, in learning solubilities of substances.

Although this is true, it is also unfortunately true that there are few properties more difficult to predict than solubility. How many chemists are there who would dare to predict which of two newly discovered salts would be more soluble in water or whether the "mustard gas," used during the war, would be miscible in all proportions with gasoline or whether phosphorus would be more soluble in benzine or in chloroform?

Dr. Hildebrand felt many years ago that the scant progress made in the theory of solutions has been due largely to the fact that aqueous solutions, because of their great practical interest, have occupied the attention of chemists to the exclusion of nearly all others, and aqueous solutions are probably the most complicated of all because of the prevalance of dissociation and hydration and because water itself contains several species of molecules. Since it is always important in the development of a theory to proceed from the simplest cases, attention has been focused by the writer principally upon non-aqueous solutions. It is possible to report an amount of progress in this direction sufficient to justify a feeling of confidence that the foundation has been laid for a satisfactory treatment of the theory of solubility.

Most of the investigators of physical chemistry seem to think that osmotic pressure offers the only valid foundation for deriving the various laws having to do with solutions. The writer has chosen rather to proceed from a purely statistical law discovered by Raoult. This law states that, in a liquid mixture of two kinds of molecules, each molecule will have the same tendency to escape into the solid or vapor state that it would have if the liquid were composed entirely of molecules of its own kind. In mixtures obeying this law it is possible to calculate the solubility of either substance in the mixture, whether it be in the gaseous or solid form. We may say qualitatively that the higher the boiling point or critical temperature of a gas the less soluble it will be in any solvent; also that the higher the melting or subliming point of a solid the less soluble it will be in any solvent. Both of these statements follow from the idea that the process of solution consists in liquefaction and the farther the substance is removed from the liquid state the more difficult it is to liquefy it.

Now although physical chemists have been familiar with these principles for a long time, it has not been possible to state in advance what molecules would be sufficiently alike to behave in the ideal manner postulated by Raoult's law. We find that molecules may be very different in chemical composition and still be sufficiently alike to obey Raoult's law. It has, therefore, been necessary to search for properties which would furnish a true measure of the degree of similarity of different kinds of molecules so far as concerns attractive forces between them. This search has been successful and we are able to announce that by the aid of readily accessible data such as densities, boiling points, heats of vaporization, surface tensions, it has been possible to arrange substances according to their "internal pressures" in a table in which the near neighbors are sufficiently alike to obey Raoult's law very closely and hence to show solubilities agreeing with the calculations of solubility made on the basis of Raoult's law. On the other hand, the farther apart in the table the substances considered, the more unlike are their molecules in the sense of the attractive forces existing between them, and the less soluble they are in each other. Thus a substance at the bottom of the table would be less and less soluble as we proceed to solvents higher up. Almost without exception, the solubility data available agree with this generalization, and a number of predictions were made that have since been abundantly verified.

CHEMICALLY ACTIVE NITROGEN AND HYDROGEN

GERALD L. WENDT and A. C. GRUBB reported their success in obtaining chemically active nitrogen in the research laboratory of the University of Chicago. This form is produced by the corona discharge at 20,000 volts from a fine wire through pure nitrogen at atmospheric pressure. Under most favorable circumstances as much as 4 per cent of the nitrogen is transformed into an active form which reacts readily with hydrogen to form ammonia; with oxygen to form oxides; and with lithium, sodium, potassium, magnesium, aluminum, iron and zinc to form nitrides; and

with sulphur to form a sulphide. It is probably different from Strutt's nitrogen, which has been produced at low pressures, in that the latter gave neither ammonia nor oxides of nitrogen. Whether it is atomic or an ozone form has not been determined, but on account of its extreme stability the latter is more probable. It forms very slowly in the discharge and persists for hours afterwards, unlike the ozone forms of oxygen and hydrogen. It has a distinct odor resembling formaldehyde.

From a similar investigation on hydrogen, the authors report that the "ozone form of hydrogen" has now been prepared by the three methods—the action of alpha rays, in the vacuum electrical discharge, and in the corona at atmospheric pressure. Attempts to produce activation by means of Schumann light failed. The ozone hydrogen, or hyzone, is extremely unstable, reverting to the usual inactive form in less than a minute. Figures are given in a detailed study of the formation of ammonia from the hyzone and nitrogen, activated nitrogen and ordinary hydrogen, active nitrogen and hyzone, and mixtures of the two plain gases activated together and reacting in the corona.

Radiation and Chemical Reactivity

Eric K. Rideal described the application of the quantum theory. He stated that the kinetic energy of the molecule must not be neglected nor the relationships evolved by Plank misapplied as by some investigators in the past.

It is now generally recognized that the forces holding the atoms together are electrical in nature and that the angular momentum (Bohr) or the electromagnetic atomic flux (Bernouilli) of the valence electrons are universal constants. By the application of Plank's radiation hypothesis, it is evident that the energy changes associated with changes of state as in the latent heats of transformation or the electrolytic potentials of the elements as well as the heats of combination of elements and compounds, which all necessitate the movement of one or more valence electrons from their original to new orbits, should all be capable of calculations in terms of the various vibration frequencies of the electrons involved and the constant h of Plank's quantum formula.

The latent heat of evaporation of the elements can be calculated from the relationship $L = Nh$. Honda has calculated the latent heat of fusion and Langmuir the approximate values of the electrode potentials from the natural vibration frequencies of the atoms and the electrons, while the heats of formation of a great number of compounds have been calculated in like manner by Haber, McLewis, Bernouilli, Perrin and others.

The problem of reactivity is, however, somewhat different from the relationships discussed above and may be advanced in the form of a question. Will an atom or molecule become reactive when and only when we impart to its valence electron a quantum of energy, the critical energy increment?

Few experiments have been made to test this point. The vaporization of metal electrons (the photo-electric effect), the resonance of the vapors of sodium, iodine, mercury under suitable monochromatic radiation, the photochemical reactions, all indicate, however, the plausibility of the hypothesis.

On the other hand with the assumption of a purely kinetic critical energy increment, the Maxwellian distribution law offers a satisfactory solution to the problems of the rate of physical and chemical action, e.g., the rate of vaporization, the rate of thermionic emission or the rate of chemical reaction. According to Rice both factors are normally operative, but the kinetic contribution is small.

Attempts to accelerate the hydrolysis rate of an ester by infra-red radiation have so far yielded negative results, but calculation indicates that but a small effect is to be anticipated. Attempts have likewise been made to test the radiation hypothesis of reactivity by a study of catalytic action both homogeneous and heterogeneous. It may be assumed either that the catalyst increases the activating absorbable radiation density, suggested by the close relationship between reaction velocity and the specific inductive capacity of the medium, or, as is more probable, that it functions through the formation of an intermediate compound. This presupposes that a molecular species can exist in several possible stages of activation and differs from Baly's force field and C. N. Lewis's polar theory in that these possible stages of activation are associated with energy contents which vary *per saltum* and not continuously, corresponding to spectral lines in a Bohr atom. Thus it appears that oxygen requires activation to different extents for it to combine with activated hydrogen to form water, silicon to form silica, and ozone can possibly be formed in two distinct ways. A catalyst on this view would be easily activated itself and would react with the reactant after it has been activated by radiation which is plentiful in the medium.

It allows the reaction to proceed in the spectral region, which is more intense than that in which the reaction normally takes place; it does not alter the radiation density to suit the reaction but the reaction to suit the radiation density.

In heterogeneous catalysis we may likewise assume either an increase in the absorbable radiation density in the film in contact with the catalyst or, as is more likely, we may postulate the formation of intermediate adsorption compounds of the types suggested by Langmuir, the reactants and catalyst being activated in the usual way. In heterogeneous catalysts we have therefore two factors operative: first, those influencing surface adsorption, such as superficial area, poisons, product adsorption, excess adsorption of one reactant, slow diffusion, and, secondly, activation governed by the rates of supply of radiation of particular frequency. Thus palladium may be regarded as a better hydrogenating catalyst than iron, not because its hypothetical hydride is more labile, or because the density of the radiation which activates hydrogen is denser at the surface of the palladium than iron, but because palladium will react with hydrogen which has been slightly activated, while iron will react only after the hydrogen has received a much larger critical increment.

Hydrated Hydrogen Ions

James Kendall, of Columbia, indicated the trend of his investigation on the ionization of strong electrolytes, especially acids having both free hydrogen and hydrated hydrogen ions. His work is expected to clear up certain points on the irregularity of ion velocity under electric potential as well as give data of value in the study of solubilities and solutions.

Radium-Uranium Ratio

S. C. Lind and L. D. Roberts gave the results of their investigation on the radium-uranium ratio, which

they found to be 3.398×10^{-7}. This is in close agreement with the 1908 value.

Nitrogen Chloride

W. A. Noyes and George H. Coleman reported progress in their work on the formation of nitrogen trichloride. They have obtained a yield of a few milligrams by the use of the traveling arc in a mixture of the two gases.

Ozone and Nitrogen Oxides

F. O. Anderegg spoke on the present progress of his investigations at Purdue University on the formation of ozone and nitrogen oxides from air in the high frequency corona. He pointed out that the lack of important accomplishments in the past was due to the fact that the underlying principles were not worked out and designs were being made from too limited an amount of empirical work. He predicted that much higher yields of ozone will be obtained with low concentrations of the undesirable nitrogen oxides in the near future.

Selenium Oxychloride

Victor Lenher presented a paper on selenium oxychloride, a neglected inorganic solvent. He called attention to the fact that selenium is not a rare element, but is commonly secured from the anode mud in copper refining, by fusing with sodium nitrate and sand. This forms a selenite and tellurite which is further treated with sulphuric acid.

Selenium oxychloride is a liquid whose properties have hitherto been almost wholly neglected. The raw material, selenium, is at present a waste byproduct from the electrolytic refining of copper. From the crude material selenium oxychloride can be produced at a very low figure and by the most simple chemical procedure, the actual procedure being to bring in contact selenium dioxide and selenium tetrachloride in carbon tetrachloride solution.

Its chemical properties are such that it will likely prove a valuable reagent to the chemist. It is an excellent solvent for many of the inorganic oxides which are commonly considered to be very refractory in character. Molybdenum trioxide, for example, can readily be separated from the oxide of tungsten. The solution of molybdenum trioxide in selenium oxychloride shows a deep indigo blue color when exposed to bright light, the solution again becoming colorless when placed in the dark.

The reagent is an excellent solvent for unsaturated organic substances. The unsaturated hydrocarbons and aromatic hydrocarbons dissolve readily in the solvent, while the paraffine hydrocarbons do not. Bakelite, redmanol, the waterproof insoluble casein glue used in airplane construction, pure rubber, vulcanized rubber, asphalt and bitumen dissolve with ease. The bituminous material can be dissolved from soft coal, leaving a carbonaceous residue.

The vegetable oils mix readily with the reagent, while with raw linseed oil a rubber-like mass is formed, quite similar to that produced by the action of chloride of sulphur on certain oils.

The chemical behavior of the reagent is quite selective. Many inorganic oxides are completely insoluble in it, while others dissolve with ease, making possible many separations. Metallic sodium is not acted on by the reagent, even at 175 deg. C., while with metallic potassium a violent explosion takes place.

Study of Plant Distribution and Plant Life

D. P. Wherry, in a study of plant distribution with hydrogen ion indicators, has found that it is a matter of common observation that certain geological formations or certain types of soil are prolific with certain types of plant life. Whether the limitation is due to chemical or physical factors is in dispute, although most writers favor the physical theory, considering the texture of soil, amount of water available for the plants, climate, etc., as all-important. It is noteworthy, however, that few chemical studies have been made by these writers.

The only sound method of treating the subject is on the basis of the ionization theory, and this will be accepted eventually. Thousands of tests with many of the native soils show that plants require a definite hydrogen ion concentration. Plants belonging to the orchid family are particularly sensitive in this respect.

The speaker urged that modern physical-chemical methods be applied in the study; that instead of the p_H method, one be substituted with calculations beginning at the neutral point, and that in addition to the study of native plants, attention be paid to the soil acidity capable of giving the best yield with all of our ordinary crop plants.

Chemical Resources of the St. Louis District

O. H. Pierce, in speaking of the chemical resources of the St. Louis district, defined the position of the chemist as one who changes the raw materials into articles for the use of the people. He pointed out the importance of the two classes of raw materials, namely, the mineral and agricultural products of a district. Of these, by far the more important to the chemist are the mineral resources. J. E. Spurr, editor of *Engineering and Mining Journal*, was quoted as saying that literally and figuratively the people who control the mineral resources own the earth.

The district which was covered included all of Missouri, southern Illinois, western Kentucky and Tennessee, northern Arkansas, eastern Oklahoma and eastern Kansas. A comparison of the resources of the district with those which are considered of high importance to the chemical industries showed that the St. Louis district was very nearly self-supporting. In coal, petroleum, lead and zinc it takes a very leading part; in aluminum ore it is practically the sole contributor. This is also true of various other products of minor importance.

The agricultural products of the district are of three general types: The live stock, which contributes to the leather industry, to edible oils and fats and to glue—the live stock being of chief value; the corn-belt area, which lies to the north, contributing largely to the corn products industries; the district overlapping the cotton-producing areas, to the south, which contributes largely to the prominence of St. Louis in the cottonseed oil and cottonseed cake industries.

Chemical Warfare

Colonel Amos A. Fries, the new director of the Chemical Warfare Service and recently Brigadier General in command of the Chemical Warfare Service in France, delivered an illustrated public lecture on Wed-

nesday evening, April 14. He revealed a condition not even suspected by the general public, and that is that large quantities of poison gas made in the United States are still in storage and show no signs of deterioration. The Government did not know that this gas would be of much value, and had begun to sell quantities of it for industrial purposes. The demand of various manufacturers for these death-dealing gases has been so great that several of them will not be sold for the present for fear of cutting down these reserves.

Phosgene, one of the deadly gases in use early in the war, is now extensively used in the making of several shades of green dyes. It is also employed as a deodorizer, and on account of its effect on oxide of iron it is very valuable for bleaching sand in the making of optical glass. Out of the war gas phosgene has been evolved a means of breaking the German optical glass monopoly. The special value of phosgene as a bleaching agent was first appreciated at the Edgewood Arsenal, where it was seen that the gas had bleached the brickwork almost white.

Considerable quantities of chlorine, made originally to be compounded with other gases for military use, have been disposed of by the Government for industrial purposes, much of it being used in chlorinating the water supplies of cities. Although as yet no industrial use has been found for mustard gas, it is thought that the research along the lines of determining its uses is justified. Considerable quantities are still available.

If the deadly vapors which slay in war can also be made to serve many industrial uses, the Chemical Warfare Service would be made all the more effective.

The Government cannot afford to attempt an organization even one-tenth the size of that which brought the assistance of 1,200 technical men and 700 service assistants, and the co-operation of universities and industries during the war, now that the Chemical Warfare Service is operating on a peace basis. The Chemical Warfare Service must maintain a small research organization. There will be certain lines of investigation that can best be carried out, which no other institution desires to touch. It must have enough trained men to tell at least tentatively whether a new idea, a new substance or a new method can be successfully adapted to chemical warfare. This will involve in large measure a thorough understanding of military problems, military organization and military methods.

The thousand research men who are working throughout the United States to every one that the Chemical Warfare Service can maintain will certainly bring forth 75 to 90 per cent of all new ideas, materials and methods for use in chemical warfare. It is hoped that such knowledge and such touch with the various chemical industries may be kept and that we can count on this one and that one to produce within a given number of days, on the outbreak of war, a given quantity of gases. The Edgewood plant should be capable for at least five years, with moderate upkeep, of being put into large-scale production on short notice.

Industrial Chemistry Division

Effect of Impurities on the Metallurgy of Tungsten

Clarence W. Balke, in speaking of the effect of impurities on the metallurgy of tungsten, divided the impurities into two groups, the first being those metals which were reduced in tungsten powder in the hydrogen furnace. These included gold, platinum, iron, calcium, nickel, etc. The second group consisted of the oxides which are not reduced, such as arsenic, sodium, caesium, magnesium, lanthanum and thorium. He found that iron cobalt and nickel produced exaggerated growths when carried over into the sintering furnace, causing the bars to crack when placed in the swaging machine. Sodium and other metals cause a shrinkage of 0.04 per cent and retard the formation of the proper grain structure in the first group. Conclusions from his investigation have shown that any impurity in the process is detrimental to the proper working of tungsten metal.

Carbonization of Missouri Cannel Coals

An investigation on the carbonization of Missouri cannel coals by H. L. Dunlap and K. K. Kershner was described in detail. Five different cannel coals were subjected to destructive distillation in a gas-fired horizontal retort and the results compared with a bituminous coal coked under the same conditions. Both the oils and gases collected at different stages of the carbonization were examined.

The oils from cannel coals have a low specific gravity and consist chiefly of paraffine hydrocarbons. These oils resemble the oils obtained by low-temperature carbonization of bituminous coals. Cannel coals yield a larger quantity of gas than bituminous and this gas has a high calorific and illuminating value. Only two of the coals examined gave a coke of any commercial value. Cannel coal might be of value to mix with bituminous coals for gas production because of the high illuminating value.

Specifications for Chemical Reagents

W. D. Collins opened up an interesting discussion on problems and specifications for reagent chemicals. The chemist does not specify definite properties for the chemicals he purchases on the market. Some progress has been made on getting up a set of specifications for the chemist similar to that issued in the U. S. Pharmacopœia. The following suggestions were offered for discussion:

The American Chemical Society should establish and publish specifications consistent with good manufacturing practice. Methods of determining strength should be fully prescribed. Only impurities likely to be present should be considered. A blank test should be prescribed and the specifications should obtain no provisions for penalties, but should be left to individual dealings.

Extracting Furfural From Corncobs

H. L. Dunlap and K. K. Fischlowitz presented the results of experiments on extracting furfural from corncobs. Although furfural has hitherto been known as a comparatively rare organic chemical, a number of uses for it are already known, and the field for future developments seems very promising. The series of dyes may be produced by inter-action with various coal-tar derivatives; hard resins similar to the well-known bakelite; and also soluble resins which may find application in the varnish and lacquer trade. Furfural, although not as efficient as formaldehyde, has antiseptic and deodorizing qualities and has also found use as an insecticide. It is a yellow aromatic oil of high boiling point, 162 deg. C., and has an odor closely resembling

benzaldehyde. It may be extracted by treating sulphuric solution of corncob pulp with live steam in an Elyria enameled kettle and subsequent extraction with benzine. Theoretically about 10 to 11 per cent by weight of furfural may be extracted from the corncob pulp, but results so far obtained give a commercial extraction of 4½ per cent.

Standardization of Laboratory Apparatus and Instruments

Thomas B. Freas, in speaking on the standardization of laboratory apparatus and instruments in respect to quality, shape, size and packing, showed the need of the manufacturer for having standard sizes of laboratory apparatus so that he might produce on a quantity basis. He showed how in Columbia University 50 per cent increase in laboratory efficiency was accomplished by standardizing the apparatus used. He further proposed that a standard office be organized and supported by the American Chemical Society.

Crystal Growth in Bearing Metals

Edward J. Mahin, of Purdue University, spoke on the crystal growth in bearing metals and inclusions and ferrite crystallization in steel, together with the solubility of inclusions. Bearing metals are essentially a conglomerate of hard crystals in a soft matrix. Heat treatment does not change the structure where inclusions are encountered. Numerous metallographic slides were presented showing the migration of phosphides when metal plugs of the non-ferrous metals as well as the ferrous metals are inserted in holes drilled in a steel plate and subjected to heat treatment. The introduction of a third element has some effect on the solubility of ferrite in austenite.

Apparatus for Recovering Iodine From Kelp

Merle Randall described an installation of apparatus which is being put into operation at the Government kelp plant on the Pacific Coast for the recovery of iodine from kelp leach liquors. Iodine and decolorizing carbon will be produced.

Selenium and Tellurium

Victor Lenher, in a paper on "Selenium and Tellurium," showed that the supply of these elements was not so rare, as over 300,000 lb. of selenium and 125,000 lb. of tellurium are produced annually. The complete results of his experiments with these two metals will be produced in a later issue of Chemical & Metallurgical Engineering.

Incentive to Research

William J. Hale of the Dow Chemical Co. described a plan by which industrial concerns could offer more incentive for research in pure and applied chemistry among the graduate school men in the American universities at large and especially among the younger members of the faculties. He stated that he was convinced that large donations are available for the asking, which could be used in rewarding those men financially whose published papers were judged to be worthy of national recognition. Titles such as assistant director of research should be given by the universities to those men who have received such rewards repeatedly and thus proved their ability. Dr. Hale thought that from $500 to $1,000 should constitute the ordinary reward, which, added to the salary of an instructor, would tend to make it more sufficient, as well as make him more efficient.

Economic Status of the Chemist

A. M. Comey of the du Pont company reported the findings of the investigation on the salaries paid to chemists based on the number of years since they completed their college training. He showed that, on a total average, salaries were rapidly advanced and were not as low as has been currently believed. A motion was made to recommend to the Council that a canvass be made by sending a questionnaire to all the members of the society to determine both salaries and grades of chemical work being done.

Specific Heat of Petroleum at Different Temperatures

F. W. Bushong presented a lecture with curves showing the "Specific Heat of Petroleum at Different Temperatures," and concluded that specific heat is proportional to or a function of the absolute temperature, including the paraffines. Curves compared the work of Nernst, the Bureau of Mines, Schiff and Mayberry with the work done in the research laboratory at Kansas University.

Filter Presses

D. R. Sperry presented an instructive and interesting paper on the application of the filter press to problems in chemical industry. The filter press is a press only in that plates are held together by the action of a hand screw and is not used to squeeze the solution from the slurry. It is used to separate solids from liquids and to lixiviate the residue by a washing process. Simple washing occurs subsequent to the filtering operation, in which case the recesses containing the cakes are not completely filled before the washing. Thorough washing is in operation where the wash water is introduced behind the filter cloth.

Chemical Corrosion

D. P. Shaw gave a new method for determining chemical corrosion. The loss of weight is not taken into consideration, but rather the equivalent depth of penetration of the corroding agents in the metal over unit periods of a month's time. Corrosion depends upon the shape of the piece, the volume of the solution, the temperature, the time of exposure and the methods of cleaning test pieces. Of these the concentration and temperature are the most important features and time also has an appreciable effect in the fact that an exposure under twenty-four hours does not give reliable results. Tests should be carried on for at least forty-eight to ninety-six hours. He concluded that this was a very important subject on which little work had been done and that the three most important factors are fusion coefficient, velocity of corroding solution and the ionization coefficient.

A New Type of Catalyzer

W. D. Richardson presented a paper on a new type of catalyzer for the hydrogenation of oils and other purposes. This paper is published in full on page 793 of this issue.

Specific Heat of Heavy Mineral Oils

Herbert Bailey and C. B. Edwards presented the results of investigation on the determination of the specific heat of heavy mineral oils and described the practical application of oil for transmitting heat in chemical plants. The apparatus used was a thermos bottle equipped with a stirring arrangement and into which a nichrome coil was introduced with leads attached to a pyrometer on the outside. The results were plotted with specific heat against temperature ranges.

Potash and Reconstruction

J. W. Turrentine spoke on "Potash and Reconstruction." Upon the signing of the armistice most of the potash plants in America put out their fires, because it was thought that immediately Germany would flood the American market with all that potash which she had not exported during the period of the embargo and which in the imagination of the American producer was being piled up in Germany. Unfortunately for the American producer, this was a false alarm. Germany during the war period was not engaged in the production of anything that she didn't have immediate need for.

Now in Europe the potash monopoly, formerly entirely in the hands of Germany, is divided between the Germans and the French, the French having acquired very important and valuable potash mines which were situated in Alsace. The world hoped from this division to obtain potash under competitive conditions and at reduced cost, but one hears more of mutual understanding between these two interests to establish prices than prices being reduced through competition.

However, there is one very important difference between the present situation and that which existed before the war, and that is that where before the war the Germans sold potash to the American farmer at 60c. per unit weight delivered in New York, he is now charging his own farmer $2 a unit weight, delivered at German points. It is hard to see what chance, therefore, the American farmer has of getting potash cheaper than the German farmer. Therefore, the American finds himself between two difficulties, an exorbitant price for foreign potash and an American potash industry largely shot to pieces through lack of informed and concerted opinion.

The Summerland, Cal., Kelp Experimental Plant

He further described in a subsequent paper the experimental plant at Summerland, Cal.. which was founded for the purpose of ascertaining if any American potash industry could be based on the giant seaweed as the raw material. To date about thirty products, byproducts and derivatives have been established as obtainable from kelp when processed in the manner in vogue there. Some of these have commercial value and some have little or none. Among the products are such materials as potash and various salts of potash, table salt, crystalline iodine and various salts of iodine, ammonia in various forms, bleaching carbons of various grades, oils of different characteristics and degrees of usefulness, creosote and disinfectants and other derivatives prepared from it, pitch, prussian blue, and combustible gas; and of these potash salts, iodine, bleaching carbons, ammonia, oils and combustible gas are obtainable profitably. However, to date only potash, iodine and bleaching carbons have been put on a commercial basis and soon are to be produced on a large scale as a part of the daily operation of the plant.

Thus, three products, potash, iodine and bleaching carbon, for which America has been dependent on foreign countries, are now being produced from kelp. This dependence will be entirely wiped out with respect to iodine and bleaching carbon, and certainly at least impaired with respect to potash.

A considerable number of papers were read by title only and will appear later in the publications of the American Chemical Society.

Sugar Division

S. J. Osborn of the Great Western Sugar Co. opened the first meeting of the sugar section by showing how vital chemical control was to the beet sugar industry. He claimed that, as a matter of fact, the sugar industry leads all others in chemical control. All the operations, from those of the beet grower on down through the extraction plant and refinery, are watched for even the smallest fractions in variations of sugar percentages.

Testing and Using Saccharimeters

C. A. Browne spoke at length on testing and using saccharimeters. He announced that the first instrument to be made in America had recently been turned out at Rochester and it was hoped that during the coming year one hundred instruments would be manufactured.

Refining Sugar Juices Mechanically

F. W. Zerban gave an excellent account of some recent work in refining sugar juices by mechanical means. As is well known, such active chemicals as sulphur dioxide, lime, and acid phosphates contribute certain disadvantages as well as benefits in their use in sugar refining. Mr. Zerban used quite large amounts of Filter-Cel mixed with an imported Dutch bleaching carbon called noirit, which mechanically removed the juice impurities. The molasses obtained resembled a cane sirup and should sell at a high premium. The process was too new to derive figures as to its exact economic status, but there can be no doubt as to its feasibility.

Dye Section

Charles L. Reese, chairman of the Dye Section, in opening the proceedings of that section, said that the American dye industry gave great promise of success and its progress would be largely dependent upon favorable legislation.

The commercial aspect of the dye business is obviously of first importance; unless the industry is managed well, as a commercial enterprise, it cannot succeed even with the best technical staff and equipment. The past twelve months have not been characterized by the same rapid flow of capital to new ventures in chemical commerce, but that is a healthy rather than an unhealthy symptom, because there was a tendency to rashness evident in much of the promotion entered into just before and after the close of hostilities. The significant feature is that much has been done to put the industry on a sound basis and to safeguard the investment already made. There has been, however, considerable reluctance on the part of those in charge of the finances of the industry to make additional investments when the money was needed for the proper development of projects already under way, on account of the lack of accomplished legislation to protect this young key industry.

Encouraging Results Obtained in the Dye Industry

The dye industry is yet too young to have proved itself worthy of the confidence of those who have shown their belief in it by giving it financial support, but the recent developments have tended to show that the confidence was warranted. The technical development has been very apparent to those in close touch with the details of the industry. Yields have been pushed up with a resultant saving of material. The quality of intermediates and finished products has been very markedly improved and in addition it has been possible to increase the diversity of colors manufactured.

This is all very gratifying, but to me the most significant thing about it is not material, but rather mental—it is a measure of the rapid growth of knowledge among our technically trained men and shows, I take it, that they are entirely capable of developing that profound specialized knowledge of applied organic chemistry which is an essential of a successful dye industry.

Improvements in the Equipment of the Dye Industry

There is another pleasing feature of recent progress; designers of chemical equipment have shown that there is still much that can be done to improve the mechanics of the dye industry. They have not been content to reproduce foreign designs, they have struck out for themselves, and have already made some revolutionary improvements. This I consider very important because it shows that this industry is a fertile field for American ingenuity, and that we can expect to make very important economies in characteristically American ways.

Need of Educating the Laborers for the Kind of Work They Have to Perform

Besides the technical man there is another worker in the plant upon whom a great deal depends; he is the wage earner. Even the simplest operations about a dye plant are important and may make or mar a product. The use of a metal instead of a wooden shovel, or similar careless handling in any little particular may mean ruin to valuable material. Until the laborer learns the meaning of this there will be unnecessary trouble. I think that some effort should be made to educate the right kind of men by giving them elementary courses in chemistry, or at least by seeking to give them some understanding of their duties, so that they may learn to do them in something more than a mechanical way.

The German employers gave great attention to provision of everything possible to make their labor permanent and content; free hospitals, reading rooms, swimming pools, special classes in cooking for the girls, kindergartens for the children, all these and many other advantages were provided. I think that this is a feature of the German industry which we shall find it necessary to adopt, though in a modified form, which will suit our special conditions.

Progress of Industry Dependent on Legislation

Legislation of the utmost importance to the industry is under consideration. It is quite clear that the young industry must have protection—that is agreed to by nearly everyone—but the means of attaining the end has been the subject of much debate. It seems certain that adequate protection will be forthcoming and that a law will be enacted which will insure a far more satisfactory tariff than has ever before been in effect, one which has been formulated with the constant advice of experts.

In addition we may hope for an embargo for the next three years. It is a pity that action has been delayed so long. Even though the delay may have been justified, yet it has acted as a powerful deterrent to the erection of plants necessary for the proper expansion of the industry.

German Dye Patents

Samuel A. Tucker dealt with the classification of the 671 German dye patents owned by the Chemical Foundation which forms the largest division of any class of enemy-owned United States patents taken over by it, and covers practically all classes of dyes. The method of classification followed enables one to locate any patent either by the chemical constitution of the dye or its application. Many of the 134 patents actually licensed either by the Chemical Foundation or the Federal Trade Commission were discussed at considerable length.

A list of patents of which the Schultz number was known but which had not yet been licensed was given. The advantages in the form of license as issued by the Chemical Foundation were pointed out and the influence which the company may have on the American chemical industry was discussed.

Leather Chemistry Section

The first meeting of the Leather Section of the American Chemical Society was opened by the chairman, Dr. Louis E. Levi, with a graphic description of chemical work in the tannery. He described the difficulty with which the chemist entered the tannery twenty-five years ago as compared to the ease with which he now works in the chemical control of this industry at the present time. In these days of mineral tannage the chemist must control the tanning liquors as well as all chemicals which are bought by the purchasing agent. As the tanning of today is yet in its infancy, the research chemist has a load of precious tanning methods to uncover and operate for the great material benefit of his employer and himself.

The True Tanning Value of Vegetable Tanning Material

John Arthur Wilson and Erwin J. Kern read a paper on "The True Tanning Value of Vegetable Tanning Material," and described a new method of analysis for determining the tannin content of these materials in contrast to the present methods of the American Leather Chemists Association, which was revolutionary in the extreme. The American Leather Chemists Association method varies from 43 per cent to 198 per cent in error as compared with the new method.

The new method requires more time, but gives greater accuracy and uniform results. The hide powder used in this method is not chromed. The moisture content of the hide powder has no effect, and the analysis may be easily and effectively accomplished.

The discussion on this paper brought out the fact that the actual yield of tannin in leather when analyzed closely checks the result of the analyses.

The chemical action of tanning was defined as the formation of chemical combinations by the reaction of the proteids in the hide with acid, salt, and even bases.

The Currying of Leather for Belting

Edward E. Marbaker delivered a paper on "The Currying of Leather for Belting." The tanning of steer hides produces the heavy leather from which belting is made. The leather, as it leaves the tannery, is not suitable for belting, because it is hard, harsh and more or less cracky. It must be thoroughly scoured to free it from dirt and excess tanning extracts and loading materials when such are present. The next step is to "set out" the butt, a process which flattens out the irregularities of the surface, such as wrinkles. Subsequently greases and oils are introduced into the leather, and the final product is pliable, smooth to the touch so far as the grain is concerned, and very much stronger than the original "rough" leather. It is in this form that it is used for belting, and the process of cleansing or greasing or "stuffing" is known as "currying."

Leather for belting is tanned in the form of butts, which are hides with the heads, bellies and flanks removed. The finished butt is from 70 to 80 in. long, from 48 to 54 in. wide, and weighs from 20 to 30 lb. This may be handled whole, but usually it is cut into a center and two side pieces, these varying in width according to the kind of belting for which the leather is to be used. The scouring process is then carried out on these three pieces separately. It is purely mechanical and is carried out on machines which give a very efficient scrubbing.

The scoured leather may or may not be dried out before "stuffing," according to the process which is used. There are three general methods of stuffing: (1) the cold hand process; (2) the hot hand process; (3) dipping.

Other Papers

Other papers presented in this section were as follows:

John Arthur Wilson and Edwin A. Gallun, "The Neutral Salt Effect and Its Bearing Upon Leather Manufacture."

Erwin J. Kern, "The Determination of Sulphate in Sulphonated Oils."

Arthur W. Thomas, "A New Method for the Determination of Sulphuric Acid in Leather."

Arthur W. Thomas and M. J. Kelly, "Time Factor in the Absorption of the Constituents of Chromic Sulphate Solutions by Hide Substance."

Arthur W. Thomas and S. B. Foster, "The Conductivity Titration of Chrome Liquors."

I. Newton Kugelmass, "Physico-Colloidal Interpretations of the Tanning and Tawing Procedures."

Colloid Symposium

Under the joint chairmanship of Profs. W. D. Harkins of Chicago University and Harry N. Holmes of Oberlin College, the most important technical event of the meeting was held in the great ballroom of the Hotel Statler on Thursday morning. The various divisions of the Society suspended their activities in order that all the members might attend this symposium. There was standing room only, and most of that was occupied.

The paper by Jerome Alexander on some practical aspects of colloid chemistry was read by the chairman.

What promises to be one of the most far-reaching advances made under the stress of the recent war, when necessity literally was the mother of invention, is the discovery that by means of a suitable fixation or peptizing agent and suitable treatment very large percentages of sheet tars and finely powdered coal may be dispersed in fuel oil with a sufficient degree of permanence to enable the mixture to be stored, piped, atomized and burned practically like fuel oil itself.

Since it will at one stroke relieve the drain on the earth's rapidly diminishing stores of petroleum, as well as lead to the efficient utilization of all kinds of coal waste, such as culm, screenings, and dust, inferior fuels, such as peat and lignite, and even cellulose waste, such as slabs and sawdust, this new composite fuel may be hailed as a powerful factor in the conservation of our natural resources and as a lasting benefit to mankind.

Realizing the vital importance of the Allied oil supply in the conduct of naval, military and manufacturing operations, the German submarine bent every effort to destroy tankers. Marshal Foch is said to have cabled America, "If you don't keep up your petroleum service we shall lose the war." While the Allied navies were dealing with this peril in a most decisive fashion Lindon W. Bates, of New York, head of the Engineering Committee of the Submarine Defense Association, with the assistance of Dr. F. E. Shepperd and other chemists of the Eastman Kodak Co., courteously opened to him, developed a colloidal fuel which, by practically doubling the usefulness of every oil cargo would, of itself, have materially assisted the defeat of the Hun's efforts.

Coal or other combustible solid is prepared for dispersion by being pulverized so that about 95 per cent passes through a sieve which has one hundred meshes to the inch. This means, of course, that by far the greatest weight is in particles hundreds and thousands of times larger than colloidal dimension.

Wilder D. Bancroft followed with an appeal for more light on the nature of gelatinous precipitates. He asked why ferric-hydroxide plus a certain amount of water gave a gelatinous precipitate. Is it ferric-oxide and water? This is probably the true condition of precipitate, because when water vapor comes off continuously from the compound it finally goes over to ferric-oxide upon standing. A distinction should be made between gelatinous and colloidal precipitates.

Colloid Chemistry of Soaps and Proteins

Martin H. Fischer presented an exhaustive paper on the "Colloid Chemistry of Soaps and Proteins," illustrated by charts and many samples of colloidal soap mixtures.

On the assumption that the polymerized amino-acids which we call proteins react with bases of various sorts to form salts in the same fashion in which fatty acids unite with bases of various sorts to form soaps, the colloid behavior of the former is accounted for.

The hydration capacity of the soaps varies with the basic radical, and, in general, in the order: NH_4, K, Na, Li, Mg, Ca, Fe, Cu, Hg. It varies also with the type of fatty acid, that standing lowest in any homologous series being least hydratable. When different series are compared, the less saturated possess the lower hydration capacity.

Colloid soap jellies may be prepared from the various soaps and anhydrous solvents, like monatomic, diatomic, and triatomic alcohols, aldehydes, benzene, toluene, etc. This finding speaks against the too heavy emphasis now being placed upon purely electrical notions of stabilization in colloid systems.

Hydrophilic or lyophilic colloids are defined as dispersions coarser than molecular, of one material in a second, with the dispersed substance a solvent for the dispersion medium.

Liquid soaps may be "coagulated" by alkalis and neutral salts of various kinds even when chemical reaction between soap and added substances is impossible. The consecutive changes of setting, secondary liquefaction with progressive dehydration of the soap, and its separation in "coagulated" form are explained on the basis of union between added salt and water with production of an emulsion of salt water in soap succeeded by one of soap in salt water and ending in anhydrous soap floating upon salt water.

Chemically neutral soaps do not affect an indicator like phenolphthalein in concentrated solution. On diluting with water they turn it bright red. This means either (1) that water-in-colloid system (analogous to normal cells and body fluids) cannot be properly analyzed by indicator methods but only colloid-in-water systems (analogous to the secretions from the body), or (2) that the former contain no ions.

From qualitative and quantitative analogy in colloid behavior between soaps and protoplasm the latter is held, in essence, to be a salt compound of various polymerized amino-acids with potassium, sodium, magnesium, calcium, etc., which materials have "dissolved" a certain amount of water. Introduction of acid, ammonia, or potassium into this compound represents poisoning by these materials at one end of such a soap-like series (as evidenced by increased hydration capacity and increased solubility in water); introduction of the heavy metals poisoning at the other end (as evidenced by a decreased hydration capacity and the production of difficultly soluble compounds). Just as a soap anywhere in the series can, by appropriate means, be converted into any other, just so can a normal protein or living cell be "poisoned" through the addition of materials found at either extreme in the base series; or after such poisoning be changed to nearer the normal by addition of the bases in the middle series.

Considerable discussion followed this paper in which G. H. A. CLOWES delivered a very instructive little homily on the "Chemistry of Living Substances," followed with a description by H. N. HOLMES and an exhibition of a 10 per cent dispersion of calcium stearate with machine oil and water to form a gel. If the mixture is allowed to set and cool it forms a gel, but if stirred while cooling a smooth grease is obtained. The stirring of the gel after it is cooled gives a mixture of curd and thin liquid which never attains the consistency of the grease as mentioned in the first instance. This is an example of a very intimate mixture in the case of forming grease, and in the second case, one of minor emulsion.

VEGETABLE TANNING AS A COLLOID-CHEMICAL PROCESS

A remarkable paper in more ways than one was that presented by JOHN ARTHUR WILSON on "Vegetable Tanning as a Colloid-Chemical Process." It is rare, indeed, that as valuable a contribution is made to an industry as this one in which the results of four years of intensive research were revealed. The paper is also a leading contribution to pure science.

Preliminary to vegetable tanning, a hide is freed from hair, epidermis, and adipose tissue, leaving only the corium, which consists chiefly of bundles of collagen fibers. The prepared hide is then hung in a very weak solution of the tanning material and moved to a stronger liquor each day or two until completely tanned. Vegetable tanning, then, is simply the reaction taking place between the substance collagen and the soluble matter extracted from certain vegetable materials and known as tannin. It is with the mechanism of this reaction that the paper deals.

Any continuous piece of collagen, such as a hide fiber, is believed to be made up, not of individual molecules, but of chains of atoms forming a three-dimension network with interstices, while too small to be detected with the microscope, yet very much larger than the simpler molecules and ions. A hide fiber may thus be looked upon as a single large molecule. This structure gives collagen an enormous surface per unit mass and is probably responsible for its colloidal properties.

In practice, all tan liquors are slightly acid and, when the hide is immersed, water and some of the soluble matter, including acid, diffuse into the interstices of the collagen network. But the collagen readily combines with the hydrogen ions of this acid, leaving the corresponding negative ions in the solution immediately in contact with the network. Now the presence in the absorbed solution of these negative ions balanced only by the electrical charge on the network causes an unequal distribution of all ions between the absorbed and unabsorbed solutions, and this in turn causes an electrical difference of potential to be set up between the two solutions, which can be varied at will, within limits, by the proper addition of acids or salts.

On the other hand, the tannin particles are negatively charged and balanced by an equivalent number of positive ions confined to the thin film of solution immediately in contact with the surface of the tannin particles. But the presence of these positive ions results in an unequal distribution of all ions, and therefore in an electrical difference of potential, between the surface film of solution and the main body of solution. However, this potential difference will be of sign opposite to that in the case of the collagen. Hence the surface film surrounding the tannin particles will tend to merge with the solution in contact with the collagen network; and when this occurs, the positively charged collagen and negatively charged tannin will neutralize each other by combination, forming leather.

The essential practical point to be brought out is that it is not the absolute values of the electrical charges alone that determine the rate and nature of the tannage, but the differences of potential referred to, which can be varied without altering the absolute values of the charges. The application of this theory is being pushed in the hope of improving the tanning process and placing it upon a more scientific basis.

CERAMIC PROCESSES ASSOCIATED WITH COLLOID PHENOMENA

A paper by A. V. BLEININGER on the "Ceramic Processes Associated With Colloid Phenomena" was read in his absence. Clays are mixtures of finely divided aluminum silicate, of the $Al_2O_3 2SiO_2 2H_2O$ with granular matter, such as quartz, feldspar, mica, etc., and other colloids like ferric oxide and hydroxide. The particles are of the magnitude of 5μ, or smaller. Clay suspended in water is affected in a pronounced manner by alkalis, salts and acids. The former tend to deflocculate it, the latter two cause coagulation. Both phenomena occur in

phases. Absorption of the basic ion of salts is characteristic, the acid ion remaining in the dispersing medium. Deflocculation is employed in the purification of clays and in the casting process. Measurements of the fluidity of clay suspensions offer the most convenient means of detecting the changes caused by the presence of reagents, though the distinction made by Bingham between viscous and plastic flow must be kept in mind.

The migration of the negatively charged clay particles to the positive electrode within the field of a direct current is the basis of the invention of Schwerin for the purification of clays. The addition of small amounts of NaCl increases apparently the charge of the clay particles and facilitates their deposition. The removal of the impurities from clay is, however, not accomplished through the electrical separation but independent of the latter by previous treatment with NaCl.

The plasticity of clays is associated with flow under pressure and a finite yield point as distinguished from viscous flow showing zero yield point, as proposed by Bingham. The water content, contraction on drying and the capillary flow of water to the surface of the clay are affected by the presence of electrolytes, especially those whose bases show higher valences.

Upon drying and retempering, clay shows more or less of a "set," associated with decreased plasticity, the more pronounced the higher the temperature. Completely dried and dehydrated clay is exceedingly hygroscopic and absorbs vapors with avidity. Dehydrated clay also possesses the properties of a catalyst in certain reactions and combines with bases like calcium hydrate at atmospheric temperature. Dehydration is associated with increase in volume and, of course, is endothermic.

In the firing of clay, contraction of the external volume takes place due to the effect of surface tension and the lowered viscosity upon heating. With maximum contraction and closing of the pore space the state of vitrification is reached. The mass of the clay itself undergoes expansion upon heating irrespective of the external contraction. The relation between temperature, time and contraction is a most valuable one for expressing the heat work done upon clays and other silicates and oxides. Vapor pressure likewise is a probable factor in the condensation of substances like magnesia, coal, carbon, etc., or in mixtures of inert oxides with those of higher vapor tension. The end result of the heating process tends toward the partial elimination of the colloid and the substitution of the anisotropic phase.

Prof. W. D. HARKINS followed with a brilliant address on surface energy, and the symposium was concluded by an appeal from ARTHUR W. THOMAS of Columbia University for reforms in colloid nomenclature.

Electron Society

The Electron Society was organized in December, 1919, to foster researches that may lead to the discovery of an electron formula of the physical or mechanical universe. Meetings are held once a month (excepting July and August) at the Engineering Societies Building, New York City, and are followed by informal round-table discussions of Einstein's theory, Newton's law, behavior of electrons, planetary motion, absolute motion, conservation of energy, etc. For information as to membership, dues, etc., address E. M. V. Leewah, secretary, Engineering Societies Building, New York.

Secretary Alexander Recommends Saving of All Waste Paper

In referring to his recent appeal for the conservation of waste, Secretary of Commerce Alexander made the following statement, urging the saving of all waste paper:

> Following my appeal of last week to save waste and turn it back into the channels of trade, I wish to call attention to the importance of saving all waste paper. Attention has been called quite a number of times lately to the vital shortage in paper, and if the general public could realize how a shortage of paper affects its daily life I feel sure that a saving and utilization of all waste paper would be made.
>
> Many of the better grades of waste paper are used as pure substitutes for ground wood pulp and are used in making all kinds of book, bond, ledger and writing papers. If this kind of waste was not used to some extent, there would exist an even greater shortage of wood pulp from which most of our printing papers and newsprint paper is made. The waste paper used in the above list consists of old magazines, periodicals, books, and all kinds of printed matter in general. Every pound of this waste that is saved and marketed prevents the use of original wood pulp made direct from our trees.
>
> The largest tonnage of waste paper is called "common mixed," and consists of any and every sort and scrap of paper, such as newspapers, waste from the offices, stores, public buildings, and the homes. The chief use of this kind of waste is for paper boxes, roofing and building boards, paper shipping containers (which carry up to 100 pounds of freight or express), and wrapping paper. More than 2,000,000 tons of ordinary waste paper is used for boxes and shipping containers alone. The public is so accustomed to having its goods in paper boxes that it would be dumfounded to find their use seriously curtailed, and this is what will happen if we do not look more toward the utilization of waste. The use of waste papers for this purpose prevents the consumption of over 1,000,000,000 ft. of lumber annually and is increasing daily. The utilization of waste must keep pace with this to prevent a direct use of our trees for the wood pulp. At the present time there is very little original wood pulp used for paper-board boxes.
>
> In addition to the saving of trees in the making of paper board, there is another very great saving of lumber through the use of paper "shipping cases," which are used instead of wood boxes. Reports show that it would require more than half a billion feet of lumber annually to replace the "paper" shipping cases now used by almost every manufacturer in the United States.
>
> In most towns and cities there are dealers in waste paper and other salvageable material such as rags, rubber, metals, etc., who will pay a fair price for what otherwise would be thrown away or burned.
>
> The Department of Commerce still has on hand a limited number of two publications on waste reclamation which it will be glad to send to interested persons. These publications will show what one large city has done to develop a city-wide system of waste reclamation for the home, store, and factory, and the other will give some pointers on how to organize and operate the service.

German Export and Domestic Prices for Iron

The Cologne *Gazette* announces that numerous orders for iron bars are being placed in Germany by many countries. Orders from Belgium, France, Italy and Holland are especially numerous and price seems to be a minor consideration. The *Gazette* sees in this dependence on the German iron industry a means of improving mark exchange, and gives the following list of prevailing export prices: For exports to Belgium, 1,225 francs per ton; to Holland, 230 florins; to Switzerland, Italy and Greece, 500 Swiss francs; to Spain, 500 pesetas; to Sweden, 415 crowns; to Norway, 450 crowns; and to Denmark, 500 crowns. These prices are much higher than those fixed for domestic deliveries, which range from 2,620 to 2,900 marks per ton.

Abstracts of Papers Read at the Fifth Annual Meeting of T.A.P.P.I.

Pulp From Cottonseed Linters—Fuel From Waste Sulphite Liquor—Soda Salts From Black Ash—Limestone for Bisulphite Liquor Manufacture—A Revolution in Paper Machine Drive—Liquid Sulphur Dioxide in Sulphite Pulp Manufacture

A GENERAL account of the social activities of the recent T.A.P.P.I. meeting was given in the last issue of CHEMICAL & METALLURGICAL ENGINEERING. Their technical sessions were no less valuable and interesting, as may be surmised from the abstracts of some of the papers given below.

PULP FROM COTTON LINTERS

Otto Kress and Sidney D. Wells read a paper on "Pulp From Cotton Linters," in which they point out that extensive mill trials on the pulping of cotton linters have demonstrated conclusively that they are far superior in paper-making qualities to hull fiber. The latter material has received considerable investigation during the past year, but the low yields and the comparatively poor quality of the bleached pulp obtained have led investigators to believe that second cut linters offer greater possibilities. This grade of linters can be pulped by the ordinary soda pulp equipment with a chemical consumption not to exceed 10 lb. of caustic soda per 100 lb. of dry fiber, and can furthermore be economically bleached with 2 lb. of 35 per cent bleaching powder. Cotton linter pulp will produce a stronger sheet of paper than hull fiber on account of its greater fiber length and the cost of conversion into paper stock is much lower in proportion to the value of the product obtained.

FUEL FROM WASTE SULPHITE LIQUOR

"Fuel From Waste Sulphite Liquor" was discussed by George Barsky and Ralph H. McKee. Great developments during the last few years in boiler design and boiler practice, the burning of powdered coal, and of oil, have made possible the profitable use of concentrated waste sulphite liquor as a fuel. The solid material of the waste liquor has sufficient fuel value to evaporate the liquor and enough in addition to supply power or steam for other purposes. Owing to the colloidal nature of sulphite liquors, the boiling point does not change appreciably during the course of evaporation and hence it lends itself admirably for use in a thermo-compressor evaporator. In this form of apparatus there is only a small difference of temperature between the heated and the heating side and if operating with 150 lb. steam and connected to a double-effect evaporator (i.e., comprising a triple-effect evaporator, the first effect of which is a thermo-compressor), it is possible to evaporate 5.4 lb. of water per lb. of 150-lb. steam used. This amounts to 0.185 lb. of high-pressure steam as compared to 0.276 lb. of low-pressure steam for quadruple effect. Experiments have been conducted using both raw liquor and air-fermented liquor and the following figures are representative of the results obtained per ton of pulp:

	Raw Liquor	Air-fermented Liquor
Pounds of 150-lb. steam that can be made..	7,450	5,830
Pounds of water that must be evaporated...	12,480	10,000

The steam generated can be used for the development of power in non-condensing steam engines and the exhaust could in turn be used to evaporate the liquor in multiple-effect evaporators. In terms of fuel values the net combustible material in the raw liquor is equivalent to 780 lb. of 14,000-B.t.u. coal and in the fermented liquor, 610 lb. per ton of pulp produced.

EXTRACTION OF SODA SALTS FROM BLACK ASH

Instead of the usual method of extracting soda salts from black ash in leaching cells, George M. Vrostel suggested a more efficient method presenting many decided advantages. His plan is to leach uniformly ground ash on a rotary vacuum filter. The process would be continuous and would make it possible to reduce the volume of the resulting liquor considerably. He also claimed that a more complete extraction is effected and that the process can be controlled to a much greater extent than the ordinary leaching process.

LIMESTONE ANALYSIS AND EVOLUTION FOR BISULPHITE LIQUOR MANUFACTURE

"Limestone Analysis and Evolution for Bisulphite Liquor Manufacture" was discussed by W. E. Byron Baker. In the preparation of bisulphite liquors for the manufacture of sulphite pulp the character of the limestone used is an important factor. The relative degree of success in the operation of the limestone towers is dependent upon certain characteristics in the stone, and the quality of the pulp produced in cooking is influenced by the extent of impurities in the stone. The author outlined detailed methods of analysis for the determination of insoluble carbonaceous matter, silica, insoluble inorganic matter, iron, aluminum oxide, calcium oxide, magnesium oxide, alkali metal oxides, carbon dioxide, sulphur trioxide, sulphur as sulphide, hygroscopic moisture and combined water. In addition to the above it is sometimes desirable to know the mineralogical constitution of the stone, or at least determine the form in which the calcium and magnesium carbonates exist.

REVOLUTION IN PAPER MACHINE DRIVE

"A Revolution in Paper Machine Drive" was described by Stephen A. Staege. He noted that heretofore paper machines have been driven entirely by a mechanical system and the application of a sectional individual motor drive has never met with success. It is not because of any disinclination on the part of the paper industry to accept individual motor drive that the old mechanical systems have been so long continued in use, but because of the inability of the electrical apparatus heretofore available to meet the exacting speed regulation required of this type of sectional drive. The disadvantage of the mechanical system is that it requires

too much space, power, and repairs for its installation, and in the past few years great effort has been concentrated on the problem of so controlling the speed of sectional motor drives that their relative speeds should not vary more than 0.1 per cent. This has been accomplished and it has been demonstrated that with sectional individual motor drive the variable speed line of the paper machine can be driven with approximately half of the power required where mechanical drive is used on account of the great reduction in power losses. It is also possible greatly to increase speed and production.

Advantages of Liquid Sulphur Dioxide in Sulphite Pulp Manufacture

"Advantages of Liquid Sulphur Dioxide in Sulphite Pulp Manufacture" was discussed by Vance P. Edwards. He noted that the production of liquid sulphur dioxide from smelter smoke has long been recognized as a possibility, but previous to the World War no liquid sulphur dioxide from any source was produced in this country. Prior to 1914 the Forest Products Laboratory was using liquid sulphur dioxide obtained from Germany in cylinders of approximately 200 lb. capacity. There are now, however, at least two concerns manufacturing this material on a small scale from the element sulphur and one smelter producing something in the neighborhood of fifty tons of liquid sulphur dioxide per day.

Smelters operating upon pyritic ores discharge gases carrying from 0.5 to 3 per cent sulphur dioxide out of the main stack. However, from certain of the smelting operations, such as sintering, roasting and converting, gas of much higher concentration is obtained. Gas from this source is naturally selected for liquefaction, inasmuch as high concentrations of sulphur dioxide require less total amount of gas per pound of product.

The gas is first cooled, then passed through scrubbers or precipitators which remove nearly all the suspended solids and much of the sulphuric acid mist. After leaving, the gas is passed into absorption towers, where a strong aqueous solution of sulphur dioxide is made. In actual operation the strength of this solution is in the neighborhood of 1 per cent. The dissolved gas is next removed by agitation and heat, then cooled, dried and compressed to 60 to 70 lb., again cooled to 20 deg. C., at which temperature and pressure it is liquefied. Depending upon local conditions, it is estimated that liquid sulphur dioxide can be produced at a cost of about $10 per ton. To this must be added tank car equipment and transportation charges.

The value of liquid sulphur dioxide for acid making and its advantages in cooking are to a certain extent unknown quantities, though it can certainly be assumed that it is worth in excess of its equivalent weight in sulphur. That is, if sulphur cost $24 a ton at the mill, liquid sulphur dioxide is worth more than $12. Neglecting any of the chemical advantages due to the use of liquid sulphur dioxide, it is estimated that the lower handling charges and simplified mechanical operation alone would permit $15 being paid for this material.

In addition the author feels that liquid SO_2 has other and more important advantages over elemental sulphur when used in acid making. Briefly enumerated, these are: freedom from sulphuric acid and sublimed sulphur; elimination of burners and coolers; smaller piping necessary, and that may be of iron; stronger acid and shorter make-up time due to the more concentrated gas, and in the summer the acid plant may be independent of cooling water.

Sulphuric acid most frequently causes a loss of 20 lb. of sulphur per ton of pulp in addition to the cost of the lime which is precipitated. On the above basis this amounts to 35 lb. of calcium oxide per ton. The material loss from these items alone can easily amount to 35c. a ton of pulp made, and in many cases more. Indirect and more serious losses are incurred due to the cost of cleaning and the rapid depreciation of such equipment. A saturated solution of clear cooking acid can carry about 20 lb. of calcium sulphate in the liquid per ton of pulp. This is precipitated at cooking temperatures and could easily form a protective coating over the ends of the chips, effectually plugging the pores and seriously retarding penetration by the cooking acid, thus causing unevenly cooked pulp.

The relative advantages arising from the use of stronger acid in cooking have been repeatedly proved. It would be expected that increased yield, due to more even penetration, would be obtained, together with a shorter cooking time and lower bleach consumption. Such experiments as Mr. Edwards has made indicate that an acid containing double the SO_2 concentration usually employed decreases the time by 25 per cent, and increases the normal yield 10 per cent. Using the above as a basis of calculation, a digester making two cooks a day would add three cooks a week to the next output. The increased saving due to greater yields would amount to about 100 lb. on a cord of wood; in other words, one would be getting 1,100 lb. for the present cost of 1,000 lb. In the case of a 10-ton digester, the weekly output due to shorter cooking would be increased from 120 to 150 tons, while the higher yield would add 15 tons, bringing the total to 165 tons, or a 37½ per cent increase.

Liquid sulphur dioxide upon expansion absorbs 94 B.t.u. per lb., and it is conceivable that the cooling water for relief lines could be used to supply at least part of this heat. Also it would be possible to pass the cooled relief gases directly into the acid system, regulating the flow of gas from storage tanks to suit conditions. This, of course, would be impossible if the gas supply was obtained from burners. The reclaimed liquor would be collected in a separate tank and there would be no raw acid tanks.

Against these advantages must be charged the various alterations necessary and the enlarging of the recovery system to handle the greatly increased amount of gas from the digesters.

Production of Metals in Mexico Since 1916

Statistics showing the production of metals in Mexico from 1916 to September, 1919, have been published in *Iniciativa de la Ley de Ingresos* for the fiscal year 1920. The following table, taken from the publication mentioned, gives the production for 1916, 1917, 1918, and 1919 (January to September) (1 kilo = 2.204 lb.):

Metals	1916 Kilos	1917 Kilos	1918 Kilos	1919 (Jan.-Sept.) Kilos
Gold	11,748	23,543	25,313	17,208
Silver	926,142	1,306,988	1,944,512	1,462,255
Copper	28,411,218	50,985,923	70,223,454	38,170,209
Lead	19,970,986	61,121,752	98,837,154	50,533,765
Zinc	37,449,226	14,757,333	20,698,995	6,499,060
Antimony	828,767	2,646,544	3,268,546	470,778
Tin	292	9,214	13,537	1,588
Tungsten	12,250	187,637	149,486	21,969
Molybdenum	.....	.....	27,371	1,767
Manganese	.....	73,387	2,878,383	2,137,484
Mercury	.....	33,132	163,598	85,399
Arsenic	.....	1,284,820	1,881,011	1,611,250
Amorphous graphite	470,313	420,046	6,190,849	3,758,714

Consumption of Inorganic Nitrogen in the United States

A Study Prepared in the Nitrate Division of the Ordnance Department in an Effort to Forecast the Future Consumption of Inorganic Nitrogen in the United States, Based on Conditions During the Last Twenty Years

By Major D. P. GAILLARD
Nitrate Division, Ordnance Department, U. S. A.

EDITOR'S NOTE. This is the first of two articles prepared by Major Gaillard. The second will discuss in detail the supply of inorganic nitrogen in the United States, and will contain a summary in which the probable consumption and expected supply will be compared.

THE consumption of nitrogen has been increasing so rapidly, not only in the United States but throughout the world, that in order to study it intelligently it is not satisfactory to consider merely one year, and study conditions during that year, but the trend of conditions from year to year must also be studied.

Statistics are available giving the total supply of nitrogen in this country during each of the last twenty years. As to just how this nitrogen was used, equally reliable information is not available, but a fairly accurate estimate can be made for each year. There are sometimes appreciable stocks of nitrogenous materials carried over from one year to be used up in the next. In this study, however, the consumption for each year has been assumed to equal the supply for that year. If in one year by this method the consumption is too high, the next year it will be correspondingly too low, and any relatively small errors so introduced will neutralize themselves in studying the general trend of conditions over a period of years.

The consumption of nitrogen may be broadly divided into three parts, the agricultural, the industrial and the military. The nitrogen exported must also be included with the consumption.

In this study each of these broader divisions will be considered separately, leading finally to a consideration of the resultant conditions as to total consumption and supply.

Nitrogen Consumed in Agriculture

General

Nitrogen, together with phosphorus and potassium, is essential to the growth of plant life, and all fertilizer contains one or more of these elements, and most fertilizers contain all three. Of these, nitrogen is as important as any and, in the proportion ordinarily used, is the most expensive of the three.

In the United States it is customary for the fertilizer manufacturer to mix, in various given proportions, materials containing these three elements, which are bagged and sold as mixed fertilizer to the farmer, probably 80 per cent of the fertilizer used in this country being in the form of mixed goods.

The nitrogen in fertilizers is derived from two classes of materials: organic, or animal and vegetable materials, and inorganic, or mineral and chemical materials. The most important organic materials are cottonseed meal and animal tankage, the latter a waste product of the meat-packing industry. Other organic materials used are garbage, fish scrap, hair, horns, scrap leather, etc. The inorganic materials are Chilean nitrate and sulphate of ammonia—the form in which nitrogen is usually recovered from the coke ovens; to a much less extent cyanamide—one of the forms in which nitrogen is fixed from the atmosphere—and a very small amount of other chemicals.

In 1917, according to statistics gathered by the Department of Agriculture, a little less than half of the total nitrogen in mixed fertilizers was furnished by inorganic materials, Chilean nitrate supplying about three-fifths of this, sulphate of ammonia about one-third and miscellaneous materials the remainder. If we include the Chilean nitrate sold for separate application to the soil, about 60 per cent of the nitrogen sold for fertilizer would come from inorganic materials. Of the organic nitrogen about equal quantities were furnished by cottonseed meal and tankage, the two together supplying about 60 per cent of the organic nitrogen.

Use of Fertilizer in the Past

Commercial fertilizers first began to be used in this country about fifty years ago, and their use has increased steadily since that time. By 1904 the value of the fertilizers sold was ten times their value in 1869. From 1904 to 1914 the growth was very much more rapid, the value of the products in 1914 being three times, and the total tonnage of fertilizers manufactured being approximately two and a half times, the amounts in 1904.

Statistics available on the manufacture of fertilizer in the United States in the past are as follows:

FROM U. S. CENSUS STATISTICS

Year	Tons of Fertilizer Manufactured	Per Cent of Increase for 5-Yr. Period	Per Cent of Increase for 10-Yr. Period	Per Cent of Increase for 15-Yr. Period
1899	2,887,000			
1904	3,592,000	24		
1909	5,618,000	57	94	
1914	8,432,000	50	135	192

FROM THE AMERICAN FERTILIZER HANDBOOK AND FROM DEPARTMENT OF AGRICULTURE BULLETIN NO. 798

1909	4,900,000	1914	*7,626,000
1910	5,737,000	1915	5,783,000
1911	6,332,000	1916	5,583,000
1912	6,105,000	1917	6,592,000
1913	6,760,000	1918	†7,011,000

* 56 per cent increase over 1909. † 26 per cent increase over 1916.

It is to be noted that in the ten years prior to 1914 the use of commercial fertilizers more than doubled, the rate of growth in each 5-yr. period being substantially the same. 1915, owing to the influence of the war, with the abnormally low price received for the cotton crop and the demoralization of the fertilizer industry, the consumption of fertilizer decreased very

considerably. There was a still further slight decrease in 1916, but since that time the consumption has been increasing at approximately the rate that prevailed from 1909 to 1914. Exact figures for 1919 are not yet available, but it is estimated that the consumption last year was in the neighborhood of 7,500,000 tons, and while the 1920 consumption may actually be smaller than that last year, it will be due to the extreme shortage that has prevailed and is prevailing in all fertilizer materials, a shortage that has caused the abnormally high price of fertilizer materials now obtaining. It is evident that the demand for fertilizer is not being met and the present consumption is a matter of present supply rather than of present demand.

Although the South has been and is the principal user of fertilizer, in the last few years having taken about 60 per cent of the total production, the Middle West has shown the largest rate of growth from 1910 to 1914 and since 1916, and now uses over 10 per cent of the total. New England, which uses about 6 per cent, has shown the next most rapid growth, and the Middle Atlantic States, using a little less than 20 per cent, have a growth slightly greater than that of the South.

Need for Fertilizers

This very rapid growth in the use of fertilizers in the United States is only repeating what has taken place in Europe. As the land has become depleted, the crop yields have fallen off and to bring the soil back to its original fertility it has been necessary to supply fertilizer to make up the deficiency. This tendency was first felt in the South and the East, as the soil there had been under cultivation for a longer period, and was particularly marked in the South, where conditions made rotation of crops very difficult and where cotton is usually planted on the same land year after year. A large part of the soils in the corn belt of the Middle West is now or will soon become depleted in nitrogen and the use of fertilizers in that section must inevitably increase even faster in the future than in the past.

If the price of fertilizer were low enough, there is for practical purposes almost no limit to the amount that could be advantageously used. It has been estimated by Dr. Lipman, director of the New Jersey Agricultural Experiment Station, that the annual loss of nitrogen from all land under cultivation in the United States which is not replaced by manure, by the nitrogen supplied by plowing under leguminous crops, by atmospheric precipitation in the form of rain and snow and by the present use of commercial fertilizer amounts to between 3,000,000 and 4,000,000 tons of nitrogen, to replace all of which would take from 15,000,000 to 20,000,000 tons of sulphate of ammonia, or from 150,000,000 to 200,000,000 tons of ordinary commercial mixed fertilizer.

It would not pay now or in the immediate future to use fertilizer to any such extent on all of the land under cultivation, but these huge figures represent the upper limit to the use of nitrogen in fertilizer, and show how far from that limit the present consumption is.

At present it will pay to use fertilizer in many cases where it did not pay before the war; the value of land in most agricultural sections of the country has increased very considerably; the cost of farm labor has increased even more rapidly; and the value of the farm products in general is much higher than before the war. The use of fertilizer which causes a greater production per unit of land and per unit of farm labor, provided this fertilizer can be secured at a reasonable price, must therefore inevitably increase, and, assuming that a sufficient supply is available, it is entirely reasonable to assume that it will increase even faster than it did before the war.

Future Use of Fertilizers

It will be seen that from 1899 to 1914 the consumption of fertilizer in the country practically tripled, an increase substantially equivalent to an increase each year of 7½ per cent over the previous year. The growth during the last five years of this period was at an even greater rate, and since the slump in 1915 and 1916 the recovery has been practically at this same rate. It is therefore conservative to assume, in view of the factors mentioned before, which favor the increasing use of fertilizer even more than was the case before the war, that this growth will continue at this pre-war rate of 7½ per cent per year at least until 1924; that is, that there will be an average increase each year in the next five years of 7½ per cent over the preceding year. This would give a total fertilizer consumption for 1924 of 10,500,000 tons, a figure which, it is to be noted, is only about 25 per cent higher than the figure as actually reported by the census statistics for 1914—ten years earlier. The rate of growth from 1924 to 1930 has been assumed to continue uniformly at a somewhat slower rate, an increase little less than 800,000 tons a year, which gives for 1930 a total consumption of 15,200,000 tons.

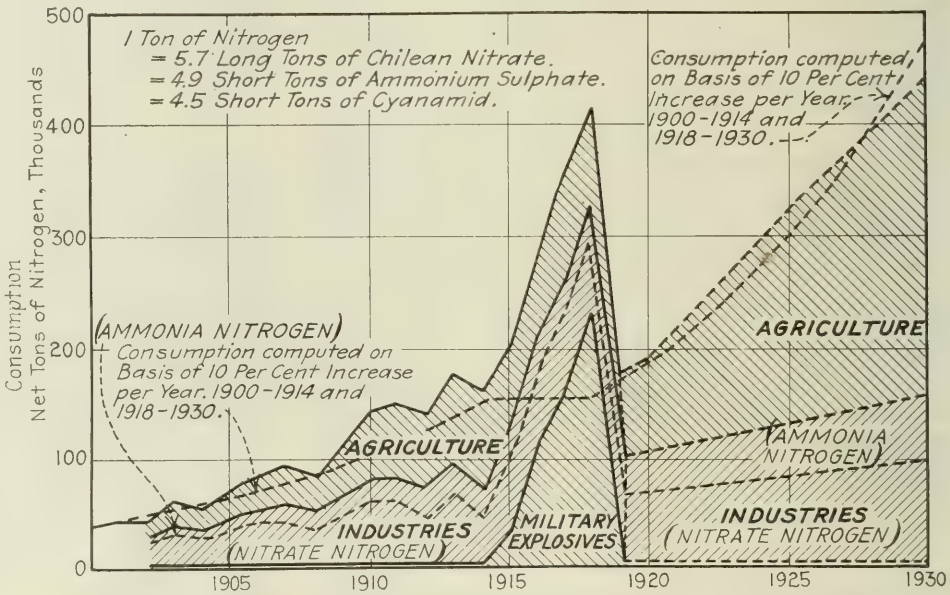


CHART SHOWING CONSUMPTION OF NITROGEN IN THE UNITED STATES

All of the organic nitrogenous materials are the byproducts of other industries, principally the meat-

packing and cottonseed oil industries. Although there has been a steady growth in these industries in the last twenty years, this growth has not been nearly so great as the growth in the consumption of fertilizer. Moreover, there has been a steadily increasing use both of cottonseed meal and animal tankage for feeding purposes, this use increasing especially rapidly in the last three or four years. The net result of this has been to make available for fertilizer use a slowly increasing amount of organic nitrogen up to two or three or four years ago, since which time there has been a considerable decrease—a decrease especially marked in the last year. During the past few months, garbage tankage from cities like Pittsburgh and Baltimore, which was formerly used exclusively for fertilizer purposes, has been entirely withdrawn for feeding purposes.

It is to be noted that at present the price of cottonseed meal is approximately the same as corn meal, about three-fourths that of oatmeal, and about two-thirds that of wheat flour. At these relative prices, it will naturally be evident why cottonseed meal is going into feed rather than into fertilizer.

Figures compiled by the Department of Agriculture show that in 1917 and 1918 about half of the high-grade animal tankage was being used for feed and about two-thirds of the cottonseed meal. Since then this proportion has undoubtedly increased. That these materials are now primarily feeds and only secondarily fertilizers is shown further by the course of their prices in the last year or so, during which time their prices have been controlled by the feedstuff market rather than by the prices of their competitive fertilizer nitrogenous materials, Chilean nitrate and sulphate of ammonia.

Increasing Use of Inorganic Nitrogen in Fertilizers

Some figures may help to show just how these tendencies have affected the proportions of organic and inorganic nitrogen used in fertilizers. In 1899, statistics indicate, about five-sixths of the nitrogen in mixed fertilizers, together with that used separately, came from organic nitrogenous materials; in 1904 about three-quarters; in 1909 slightly over half; and in 1914 slightly under a half, and in 1919 somewhat over a third. It is estimated that in 1924 this proportion will not be more than a fifth, and in 1930 not more than a tenth, as in 1924 there will be available not more than 45,000 tons of nitrogen from organic sources, about 60 per cent of the amount available in 1917, and in 1930 not more than 28,000 tons of nitrogen, about 40 per cent of the amount available in 1917.

Future Use of Inorganic Nitrogen

The estimated consumption of 10,500,000 tons of fertilizer in 1924 will require approximately 217,000 tons of nitrogen, not more than 45,000 tons of which can come from organic materials, leaving 172,000 tons of inorganic nitrogen to be supplied.

The estimated consumption of 15,200,000 tons of fertilizer in 1930 will require approximately 315,000 tons of nitrogen, not more than 30,000 tons of which can come from organic materials, leaving 285,000 tons of inorganic nitrogen to be supplied.

In other words, inorganic nitrogen must supply not only all the nitrogen requirements in addition to those as present existing, but must replace in 1924 about 40 per cent, and in 1930 over 60 per cent of the organic nitrogen now being used.

Nitrogen Consumed in Industries

Uses of Nitrogen in Industry

In the chemical industries of the country, in which is included the manufacture of domestic explosives, nitrogen plays a very important part. This nitrogen is consumed in two forms, as nitric acid made from Chilean nitrate and ammonia derived from the gas works and the byproduct coke ovens. At present about two-thirds of the nitrogen is consumed in the form of nitrate and about one-third in the form of ammonia.

Somewhat more than half of the nitrate used goes into the manufacture of industrial explosives, such as dynamite, blasting powder, etc., which are used not only for practically all mining and quarrying operations but to a rapidly increasing extent for road building, clearing land, digging ditches, and other labor-saving purposes. Somewhat less than half of the nitrate goes into other chemical industries, principally the production of the several nitrocellulose products which include artificial leather now almost universally used for automobile upholstery, photographic films, imitation ivory, and all forms of celluloid. It is also used to some extent in the glass industry.

Of the ammonia approximately one-quarter is used in connection with the operation of cold storage plants and for the manufacture of artificial ice, about one-third is used in the quantity production of staple chemicals, principally soda ash, ammonium chloride and sodium cyanide, about one-eighth goes into the explosive industry, principally for the manufacture of ammonium nitrate, and the remainder is used for miscellaneous purposes including the manufacture of household ammonia.

Estimates of Past Consumption

In estimating the amount of Chilean nitrate used in the industries in each of the several years the estimated amount consumed in fertilizers has been deducted from the imports for that year and the remainder taken to be the nitrate used in the industries. Of course, during the World War the military consumption has also been deducted.

In the case of ammonia, for the most of the years statistics are available from the U. S. Geological Survey, giving the total production of ammonia from byproduct coke ovens and giving that part of the production which is in the form of sulphate of ammonia. The difference between these two plus the entire ammonia output of the gas works has been taken to be that portion of the ammonia consumed in chemical industries. The relatively small part of the ammonia production from gas works which goes into the manufacture of sulphate of ammonia may be assumed, without serious error, to balance that small part of the sulphate going into the chemical industry.

The figures thus determined show that there was from 1902 to 1914 a steadily increasing use of both nitrate and ammonia in industry, the use of nitrate increasing each year by approximately 20,000 short tons (17,850 long tons), containing 3,125 tons of nitrogen, and the use of ammonia increasing each year by approximately 2,125 tons, containing 1,750 tons of nitrogen. The normalized consumption of ammonia in industries during 1919 is estimated at 42,500 tons, containing 35,000 tons of nitrogen, a figure obtained by assuming the pre-war growth to have continued to 1919. In the case of nitrate, however, the normalized consump-

tion in 1919 has been taken to be 400,000 short tons of Chilean nitrate, containing 62,500 tons of nitrogen, approximately the normalized consumption in 1914, and somewhat greater than the actual consumption in 1913. By normalized consumption is meant the consumption assuming that in 1919 the nitrogen-using industries were normally busy. The total consumption in industries of both nitrate and ammonia estimated for 1919 is then 97,500 tons of nitrogen.

The use of both nitrate and ammonia has been assumed to continue to increase from 1919 to 1930 at the pre-war rate of about 4,875 tons of nitrogen a year. It is believed that this is a very conservative estimate, as this rate of increase at the beginning of the period amounts to only 5 per cent and at the end of the period to only 3½ per cent a year. On this basis there would be consumed in industry in 1924 approximately 500,000 tons of Chilean nitrate and 53,000 tons of ammonia, together containing 120,000 tons of nitrogen, and in 1930 the estimated consumption would be 600,000 short tons of Chilean nitrate and 64,000 tons of ammonia, together containing 150,000 tons of nitrogen.

In the above discussion it has been assumed that in the future the requirements for ammonia nitrogen and for nitrate nitrogen are distinct, but developments during the war have shown that the conversion of ammonia nitrogen to nitrate nitrogen is entirely practicable and should ammonia be relatively more plentiful than nitrate and, therefore, its price appreciably lower, there is no question that a considerable part of the requirements for nitrate nitrogen would be supplied by the conversion of ammonia nitrogen.

Nitrogen Consumed in Military Explosives

Prior to the outbreak of the World War the total consumption of nitrogen in this country for military explosives increased from a few hundred tons in 1900 to between 1,000 and 2,000 tons in 1914. Exact statistics on the consumption during this period are not readily obtainable and since the use of nitrogen for this purpose is such a very small part of the total consumption, exact figures are not necessary.

In the latter part of 1915 the manufacture of explosives for the Allies began, and from then on until the armistice, in 1918, the production of military explosives increased at a tremendous rate in this country. In 1918, the year of maximum consumption, it is estimated that somewhat less than 150,000 tons of nitrogen was actually consumed in the manufacture of military explosives. At the same time a military reserve stock of Chilean nitrate was slowly being built up with the object of ultimately accumulating a sufficient quantity to last for six months should all imports be cut off; and a smaller stock of ammonium sulphate was being accumulated for the manufacture of ammonium nitrate. As a result, at the end of 1918 approximately 80,000 tons of nitrogen was on hand in the form of these stocks of material. In other words, the accumulation of these essential reserves, together with the actual consumption, required in 1918 in the neighborhood of 230,000 tons of nitrogen, equivalent to more than 1,300,000 long tons of Chilean nitrate, a quantity of nitrogen more than a third greater than the consumption for all purposes in the highest year before the World War.

The future consumption of nitrogen in military explosives so long as the United States is not involved in war will be but little larger than was the case before the war, and in fact, it may actually be even less owing to the large amounts of powder and explosives now in storage. In any event the peace-time consumption of nitrogen for military explosives will be a negligible part of the total consumption. So long, however, as this country is so largely dependent on imported nitrogen, conditions will be similar in case of a future war, and nitrogen will have to be supplied not only to meet the actual consumption, but to establish a sufficient reserve to safeguard against an enemy completely cutting off all imports.

Nitrogen Exported

In the past but little inorganic nitrogen has been exported, as this country itself has been such a heavy importer of nitrogen. A large part of the little inorganic nitrogen exported was contained in mixed fertilizers manufactured here.

However, since the practical cessation of sulphate exports from Europe, and particularly in the last year, the United States has been exporting a fairly considerable amount of sulphate of ammonia to the West Indies and to the Far East. Although no statistics are available, it has been estimated that the exports last year of inorganic nitrogen may have amounted to nearly 10 per cent of the total domestic consumption.

The question as to what may be expected in nitrogen from this country in the future is most uncertain and in this study no allowance will be made for any future exports. Undoubtedly there will be some exports, and it is very desirable that there be exports both from a commercial and a military point of view, but as these will tend to increase the requirements for nitrogen in the United States and serve only to accentuate the deficiency of the domestic supply, they will not be included.

Relation Between Mechanical Hardness and Grain Size of Carbon Steels

An investigation on this subject by the Bureau of Standards has now been completed. It shows that there is no simple relation between grain size and hardness in carbon steels such as exists, for example, in the alpha brass and other one-constituent alloys. Grain size is a factor of minor importance. The amount of distribution of the structural constituents determines the hardness to a far greater extent. The work already completed throws some light incidentally upon the magnitude of the stressing of low-carbon steel by cooling and work in order to effect the subsequent growth of grain upon annealing below the critical temperature. It is planned to extend this investigation to include a study of the effect of grain size upon other mechanical properties.

Japanese Encouraging Beet-Sugar Industry in Manchuria

As the annual sugar production of Japan is little more than half of the amount locally consumed, and as the action of Java in prohibiting the exportation of sugar for the next six months emphasized the possibilities of future shortage of sugar in Japan, the Japanese are realizing the necessity for developing a more dependable source of supply, says the *North China Commerce*. To this end they have offered rewards to the farmers of Manchuria for large crops of sugar beets, thus encouraging them to plant beets instead of customary crops.

Microstructure of Iron and Mild Steel at High Temperature*

Pronounced Decarburization Occurs When Metal Is Heated in Vacuo, Consequently Heat-Etching of Polished Surfaces Represents Largely Structure at Surface—Nature of the Surface Patterns Is Also Discussed

By HENRY S. RAWDON and HOWARD SCOTT
Physicists, Bureau of Standards

THE method of demonstrating the structure existing in a metal or alloy at high temperatures, by etching a polished sample after it has been heated to the desired temperature, is quite familiar to metallographists. The usual procedure[1, 2] is to heat the specimen, previously polished for microscopic examination, to the desired temperature, in a neutral atmosphere (hydrogen or nitrogen), then admit the etching gas (chlorine, hydrochloric acid or similar gas) for a few seconds, and finally, after flushing out the etching gas with the neutral one, cool the specimen in the neutral atmosphere. The pattern produced by etching at a definite temperature is usually taken as a record of the microstructure prevailing at that temperature. It has frequently been pointed out that changes in composition of the surface metal occur during the preliminary heating in the neutral atmosphere, so that the appearance produced by the etching at high temperature may not exactly represent the condition of the interior of the specimen. To overcome this uncertainty, the heating has sometimes been done in vacuo,[3] the etching gas being admitted when the desired temperature was reached, then pumped out and the specimen cooled in vacuo.

The studies of Rosenhain, Humfrey, and other workers[4, 5, 6, 7, 8] demonstrate that surface changes in the steel occur even when the specimens are heated in vacuo. Such changes in themselves are sufficiently pronounced to record, in the appearance of the surface, the microstructure prevailing at the temperature at which the change took place. The surface configuration or pattern thus produced, to which various names, "heat-relief," "heat-etching" and "vacuum-etching," have been applied, has been explained by Rosenhain as being due to volatilization of the surface metal. This is more marked along the crystal boundaries than over the face of the crystal itself. The change in composition of the layer immediately adjacent to the surface of a steel sample when heated in vacuo or in a neutral atmosphere has also usually been attributed to volatilization. Howe[9] has offered an entirely new and striking explanation for this phenomenon, namely, that the change in composition of the surface layer is only local and the average composition of the specimen does not change. Upon cooling a sample of steel from a high temperature, the free constituent (ferrite or cementite as the case may be) is expelled to the outside of the mother austenite crystal and thus to the surface of the specimen in those crystals which form the exterior. By repeated heatings, the layer of expelled ferrite (in the case of low-carbon steels) is augmented until the specimen has the appearance of being decarburized at the surface.

The examinations here described were made for the purpose of showing to what extent the change in composition of the surface layer, which usually accompanies heating in vacuo, affects the results of tests which may be made to reveal the microstructure existing at high temperatures. The results also throw some additional light upon the nature of the change in composition of the surface layer and also upon the formation of the surface pattern under "heat-relief" etching.

Method of Revealing Structural Changes Occurring at High Temperatures

Pure iron and low-carbon steel were chosen as typical materials for demonstration, since both materials show pronounced changes in structure accompanying some of the transformations which occur upon heating. The normal structure of each is familiar, and the microstructure at high temperature has been demonstrated by means of the etching method.

Pure Iron

A remelted electrolytic iron having the following composition was used: Carbon, 0.03 per cent; sulphur, 0.002 per cent; silicon, 0.009 per cent. By thermal analysis, the material was shown to have the following thermal characteristics: Ac_2, 768 deg.; Ac_3, 910 deg.; Ar_3, 900 deg.; Ar_2, 768 deg. C. The specimens, which were of the size used for thermal analysis (approximately 3 g.), were mounted on the end of a platinum platinum-rhodium thermocouple and heated in the evacuated tube of a differentially heated furnace of the Rosenhain type[10] to the following temperatures: 950 deg. C., above A_3; 880 deg. C., between A_3 and A_2; 700

deg. C., below Ac_1 (of steels). In each case the specimen was held for approximately 30 min. at the maximum temperature and then cooled in the evacuated furnace at an approximate rate of 0.15 deg. per second by moving the specimen to the cold end of the tube. The surface of the specimens, after heating, showed no evidence of oxidation. In most cases, particularly those heated to the highest temperatures, the surface had a slightly roughened or matte appearance.

Fig. 1 shows the surface pattern produced by heating the iron above the Ac_3 transformation. Two distinct patterns are to be seen superimposed one upon the other. One of the patterns is similar in appearance to that of pure iron as ordinarily etched at room temperature; the other network prevailing above A_3 contains numerous straight lines and many of the enclosed "grains" have the appearance of twinned crystals. This is clearly shown at *A-A* and *B-B*. The long narrow crystal is the twinned layers of a much larger crystal. Another network, outlining a second system of grains, is superimposed upon the twinned crystals.

The network delineating the straight-sided polyhedral twinned crystals is a record of the structure of the γ iron, i.e., the form existing above the A_3 transformation. The second network belongs to the crystal structure prevailing below this transformation, as seen in specimens heated to a temperature below A_3. Only one network is developed under such treatment, and this is identical with the second pattern of specimens heated above A_3. The specimen shown in Fig. 2 illustrates this, and also shows that no characteristic crystal form corresponds to the so-called β range. The appearance is the same as that of specimens heated to a temperature well below A_2 (Fig. 3) and also of samples polished and etched under ordinary conditions. This observation confirms that of Rosenhain and Humfrey, in this respect.

Fig. 3 shows the surface of a polished specimen heated to 700 deg. C. The network outlining the arrangement of the crystals appears faintly even at this relatively low temperature.

The surface of freshly heated specimens often has a "matte finish" appearance and, when viewed at an oblique angle, is seen to be considerably roughened. The volatilization occurring at high temperatures, as shown in Fig. 1 accounts partly for the matte finish. It was noted that the volatilization develops rather well defined "etching pits" on the surface, by means of which the structural orientation within the twin crystals relative to the mother crystal is plainly shown [in micrographs not reprinted]. The roughened appearance is largely due to a "buckling" of the surface of the individual crystals. In Fig. 4, a section perpendicular to the polished surface which was exposed to the heat, is demonstrated the distortion that occurs; the boundary, i.e., the trace of the polished flat surface, originally rectilinear, now consists of a series of undulations. Specimens heated to a temperature a little below A_3 show an irregular branching network within the grains themselves (Fig. 2). This is often seen in pure iron after ordinary etching for microscopic examination, particularly if the sample has been strongly heated previously, for example, specimens which have been heated several times for thermal analysis curves. Whether this bears any relation to the β change has not yet been determined.

Low-Carbon Steel

A synthetic low-carbon steel[11] having the following composition was selected as representative of this class of material: carbon, 0.18 per cent; silicon, 0.007 per cent. It had the following thermal characteristics: Ac_1, 738 deg.; Ac_2, 769 deg.; Ac_3, 840 deg; Ar_3, 792 deg.; Ar_2, 769 deg.; Ar_1, 700 deg. C. The specimens, first polished for microscopic examination, were heated in vacuo in the same manner as the pure iron, to the following temperatures, and were held approximately 30 min, at the maximum temperature: 950 deg. C., above Ac_3; 760 deg. C., above Ac_1; 700 deg. C., below Ac_1.

The slight roughening of the surface, due to the slipping, still persists at this temperature and shows that no marked volatilization has occurred at the surface. Even at this temperature the heat-relief has been sufficient to indicate clearly the islands of pearlite.

Fig. 5 is a specimen which, after polishing, was distorted enough to develop slip bands and then heated to 700 deg. C., just below the transformation Ac_1.

Fig. 6 shows the specimen of Fig. 5 after it had been

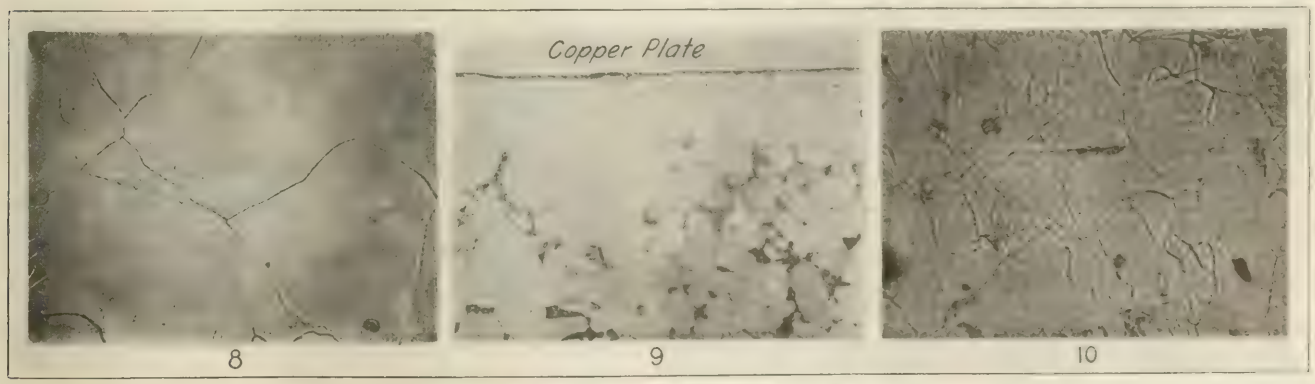
polished slightly to remove the effects of the heat-relief and then etched; it has the usual appearance of low-carbon steel. When the specimen is etched directly after heating, without any supplementary polishing, the surface darkens almost immediately and gives the appearance shown in Fig. 7. A similar pronounced darkening of ferrite, upon etching, is often observed when a specimen is finished on a polishing wheel which has been allowed to become dry, so that the surface heats considerably.

Upon heating a polished specimen of this synthetic steel above the Ac_1 transformation, the surface takes on the appearance shown in Fig. 8, which is very similar to that produced by heating below Ac_1; the position of the pre-existing pearlite islands is clearly indicated. It will be noted that the network which marks the boundaries of the ferrite crystals is now continuous *through* the pearlite areas instead of around them. When the surface is etched, without any polishing, the appearance is the same as is shown in Fig. 7. However, when the surface is slightly polished and then etched, no darkening results nor is there left any trace of the pattern developed by heat-relief. The material constituting the surface is pure ferrite; all the pearlite has been removed to a considerable depth, as is shown in Fig. 9, a section of the specimen perpendicular to the polished face, the normal appearance of the material being seen in the lower portion of the micrograph. The boundary between the outer, or carbonless, metal and the inner normal material is clearly defined, showing that the change from the outer zone to the unchanged metal of the interior is very abrupt.

If such a specimen as shown in Fig. 9 is heated for 30 min. at 950 deg. C., that is, above the Ac_3 transformation, a more clearly defined network, corresponding to the γ condition, is superimposed upon a less distinct one which shows the characteristic outlines of the α crystals. This is plainly seen in Fig. 10. The polished specimen in this instance was etched to reveal its initial structure and then heated for 30 min. at 1,000 deg. C., or well above the temperature of the Ac_3 change. The roughening of the surface, corresponding to the islands of pearlite shown by the initial etching, still persists. Upon this pattern two others are superimposed, showing respectively the crystalline condition above Ac_3 on heating, and below Ac_3 on cooling. The twin crystal which had its origin when the steel was in the γ state is seen to cut through the pre-existing islands of pearlite and to bear no relation to them. It should be borne in mind, however, that the carbide has been removed from the surface material, probably before the change to the γ state was brought about, as has been described above.

Nature and Extent of the Surface Changes Upon Heating

The magnitude of the change (apparently decarburization) which occurs in some samples (Fig. 9) makes the explanation offered by Howe mentioned at the outset



FIGS. 8 TO 10. SOFT STEEL ABOVE Ac_1

Fig. 8. Polished specimen heat-etched 30 min. at 760 deg. C. × 300.

Fig. 9. Fig. 8, electroplated, cross-cut, polished and etched with 2 per cent HNO_3 in alcohol. × 60

appear inadequate. In order to show clearly the nature of the change, and to test his explanation, a series of specimens of the low-carbon steel previously used were heated for 30 min. in vacuo at the following temperatures: 760 deg. C., above Ac_1; 820 deg. C., just below Ac_3; 890 deg. C., above Ac_3. The specimens were cooled in the furnace at the same rate as the previous ones. In each case the carbonless layer varies considerably in thickness on the same specimen. In the specimen heated at the lowest temperature, the decarburized layer is more pronounced than in those heated for the same period at higher temperatures. This is not to be attributed to a greater loss of carbon at the lower temperature, but rather to an increased rate of diffusion of carbide in iron at higher temperatures, by which any change at the surface, due to loss of carbon, is masked by a replenishment from the interior.

Fig. 11 shows the condition at the surface and Fig. 12 near the center of a specimen (low-carbon steel previously used) heated continuously for 4 hr. above Ac_3, 990 deg. C. being the maximum temperature. The structure of a sample of the same material, previously used for a series of four thermal curves, which had been held above the Ac_3 temperature for a total of 4 hr., is shown in Figs. 13 and 14. The thickness of the altered surface layer of the sample heated intermittently is somewhat greater than that of the specimen heated continuously for 4 hr. above the Ac_3 transformation temperature. The carbon content of the interior, however, as estimated from the structure, is slightly less in the specimen heated continuously than in the other one. This apparently contradictory behavior of the more strongly heated specimen is to be interpreted as further evidence of the part played by diffusion in masking the change which occurs at the surface. By comparing micrographs it was noted that a much more marked change is produced in the surface metal by a short period at the lower temperature (30 min. at 760 deg. C.) than by prolonged heating at a higher temperature (240 min. at 990 deg. C.). Whether this difference in the rate of diffusion is due entirely to temperature or partially to the allotropic condition of the iron, α or γ, can only be conjectured.

Fig. 15 shows the surface change induced in a high-carbon steel by heating four times in vacuo to a temperature above the Ac_3 transformation (950 deg. C.). The steel had the following composition: carbon, 1.28 per cent; manganese, 0.23; phosphorus, 0.017; sulphur, 0.017; silicon, 0.23 per cent. The cementite grain-envelopes do not extend entirely to the surface, as they did originally, but gradually diminish in thickness and disappear at some distance below the surface. In no case was an accumulation of cementite found, such as Howe's explanation would require. In a few areas a very thin layer of ferrite was found to have formed, as shown in Fig. 16. The conclusion is evidently warranted that the change of structure of the surface metal heated in vacuo represents loss of carbon.

Interpretation of Results

It may properly be asked, To what extent are the etching indications of steel at high temperature vitiated by changes of composition that occur in the surface metal upon heating? The results previously described show that no decarburization below the temperature of the A_1 transformation can be detected. This is due to the physical form in which the carbon exists; not until the carbon (as carbide) is in the state of a solid solution in the iron, i.e., above A_1, is there any appreciable change in the exposed surface metal. Below the A_1 transformation, the carbon occurs as a definite crystalline compound and the loss upon heating may be entirely neglected.

A very marked change, however, occurs upon heating a specimen just above the A_1 transformation, when the carbon passes from the form of crystalline cementite to a solution (of cementite) in the iron. In this form it quite readily volatilizes from the surface, so that a pronounced carbonless layer is soon formed in specimens (low-carbon steel) that are held for periods no greater than 30 min. at this temperature. The method of "heat-etching," however, serves to record the structure both before and after the change has taken place. The pronounced differential expansion of pearlite and ferrite at the A_1 transformation will account partially for this. The fact that at temperatures below A_1 the structure is clearly revealed by heat-etching, however, shows that this is not the sole cause, but that the slight general volatilization which occurs, together with the slight differences in the rate of thermal expansion of pearlitic

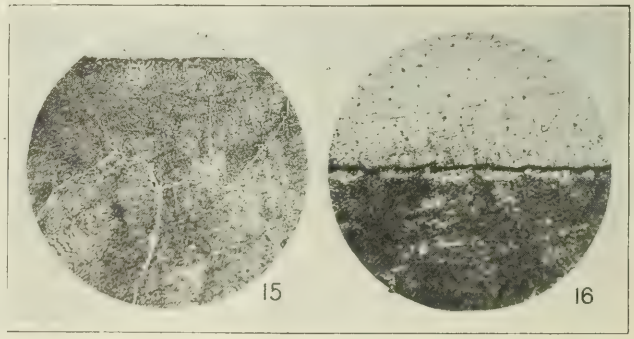

Fig. 15. Average surface condition of high-carbon steel after heating four times in vacuo to 950 deg. C. Electroplated, cross-cut, polished and etched with 2 per cent HNO_3 in alcohol. × 250.
Fig. 16. Exceptional surface condition of Fig. 15. Etched with hot sodium picrate, which turns cementite black. × 250.

steel and iron (ferrite) are sufficient to record clearly and definitely the structure of the metal. The volatilization of iron is sufficiently pronounced at the crystal boundaries to show them clearly, but across the face of the crystals there is very little loss, as is proved by the persistence of slip bands, upon heating. That the ferrite is changed somewhat is shown by its increased tendency toward oxidation. Upon slight etching with nitric acid, a distinct oxide film readily forms, coloring the ferrite very dark.

Specimens heated to temperatures higher than the A_1 transformation show a carbonless layer, which becomes thinner as the temperature is increased. This is properly to be attributed to the increased rate of diffusion of carbide in iron, by which the change at the surface is masked. The results obtained by etching specimens at the higher temperatures (heat-etching or otherwise) are more truly indicative, therefore, of the structure of the interior than those at lower temperatures, e.g., just above A_1. That the loss of iron by volatilization across the face of the crystals is very slight, even at high temperatures, is proved by the persistence of the slight roughening due to preliminary etching throughout the entire period of heating. The loss by volatilization is of a magnitude sufficient to show the crystalline structure by the production of "etching pits"; at the crystal boundaries the loss is much greater. In addition, the carbide is removed to an appreciable depth on all the exposed faces of the specimen.

Summary

1. When polished metal specimens are heated in vacuo, a record of the structure existing at the particular temperature used is inscribed on the polished surface of the specimen. This record consists of a slight roughening due to volatilization and to a slight "buckling" of the surface, due to the volume change accompanying the transformation. The terms "heat-relief," "heat-etching" and "vacuum-etching" have been applied to this method of developing the microstructure.

2. By means of heat-relief the structure of iron and steel at high temperatures is readily revealed. This is a much simpler method than the high-temperature etching often used. It appears probable that much of the effect usually attributed to etching at high temperature is due to the heating itself.

3. An appreciable change of composition and structure of the surface metal occurs in steel, upon heating. This is strongly marked just above the A_1 transformation, and becomes less so upon heating to higher temperatures, due to the increased rate of diffusion of carbon (as carbide) in iron. The structure revealed on the surface by heat-relief, or by high-temperature etching, is less representative of the interior at temperatures just above the A_1 transformation than at any other temperatures.

4. The change in composition of the surface layer of steel heated to high temperatures in vacuo is to be explained as due to volatilization of the carbide. No appreciable change takes place until the carbide enters into solid solution, i.e., above the A_1 transformation.

5. The volatilization of iron from the surface, upon heating, is very slight. Polished specimens of iron and steel, etched before being heated, retain the slight roughening due to the etching, even after pronounced heating. The volatilization of iron at the crystal boundaries is more rapid than across the face of the crystal.

Development of the Italian Chemical Industry

Owing to its close territorial proximity to Germany and to the strong foothold that Germany had obtained in its economic life, Italy was largely dependent upon Germany for many chemical products prior to the war, its own chemical industry not having reached a high stage of development. Consequently, when the outbreak of the war interfered with its usual supply, a serious shortage of chemicals occurred, and as early as November, 1915, six months after Italy's entrance into the war, the Italian Minister of Industry, Commerce and Labor called a conference to discuss ways and means of overcoming this deficiency. In June, 1916, a permanent Committee for the Chemical Industry was appointed, which has been making a thorough study of the situation and compiling data regarding Italy's production, exportation, and importation of chemicals. From the first report of this committee, which has just been published, have been taken most of the figures which are given below. While in some instances these figures are only approximate, they indicate the progress which has been made by the Italian chemical industry and the degree to which Italy has been able to free itself from its former dependence upon foreign sources of supply.

The following table illustrates clearly the great strides made in Italy during the last few years:

Chemical Products	Average Monthly Production in 1914-15 Tons	Average Monthly Production in 1918 Tons
Fatty acids	285	520
Citric acid	75	150
Nitric acid	1,525	7,150
Concentrated ammonia liquors		1,484
Anilin and derivatives		110
Crude anthracene	15	38
Crude benzol		382
Pure benzol	9	358
Carbonate of lime	20	50
Carbonate of magnesium	14	92
Mineral tar		4,139
Vegetable tar	25	50
Chlorate of sodium	16	670
Liquid chlorine	15	75
Chloride of magnesium	3	20
Chloride of zinc		63
Mineral colors:		
Lead white	230	310
Zinc white	157	247
Minium	176	838
Ultramarine		13

Acid tartrate of potassium (cream of tartar)	70	115
Carbon tetrachloride	10	74
Toluol		110
Xylol		18

The Gutta-Percha Industry

GUTTA-PERCHA is a jungle product, obtained from trees growing wild in tropical forests. Borneo, particularly Sarawak, supplies the largest quantities, although Sumatra and the Federated Malay States furnish a certain amount. Some efforts have been made to cultivate the gutta-percha tree on estates, but they do not appear to have been successful, which is due to the fact that the tree can thrive only in certain localities possessing the requisite humidity or rainfall and good drainage such as afforded by foothills, and these conditions occur very seldom outside of certain jungle areas. So far as can be learned there is only one district in Sarawak where gutta-percha trees have been cultivated with any success. This plantation has now been in existence about thirty years and is only just beginning to yield supplies in marketable quantities. In this connection it may be stated that about twenty years are required before the trees are in a fair way to produce. If trees are tapped earlier, the production is small and a great risk is run of the trees withering and dying before fully matured. This fact in itself would discourage the investment of any large capital in the industry, to say nothing of the extreme difficulty in successfully cultivating the trees outside of their native jungles.

Methods of Collection—Increase in Production

The milk of the gutta-percha is obtained by tapping, but in many cases the trees are cut down in order to obtain larger quantities. While this process does not actually destroy the life of the tree, inasmuch as new shoots will in time spring from the stump, it effectually cuts off the source of supply for many years. For this reason the felling of gutta-percha trees has, it is understood, been prohibited in Sarawak.

The latex is collected by natives, brought down to various villages, and bartered to the Chinese for rice, tapioca, salt, etc. At the present time, owing to the high cost of rice, the natives must collect considerably more than in former years in order to secure needed supplies of this staple article of diet.

The production of gutta-percha in the various districts in this section is estimated to have been between 450 and 500 long tons in 1918, while in 1919 it was between 600 and 700 tons. The production is regulated according to existing values, and, should prices advance, it is to be anticipated that for 1920 it will amount to 800 or 900 tons. It is known that the production of gutta-percha is stimulated by further special inducements being made to the natives, who are the actual collectors. Without such inducements it is not probable that any appreciable increase in the present output of the commodity will be effected.

Prices, and Factors Influencing Prices

As an example of the upward tendency in the prices asked for gutta-percha, it may be stated that "Pahang Red," which five years ago cost approximately $158 per picul (133⅓ lb.), rose to $312 at the close of 1919, with supplies even at this price practically unobtainable. Similarly, "Banjirmassin" increased from $85 to $142 during the same period, and this may be taken as a fair average of the advances made on all grades of gutta-percha during the past five years. It will thus be seen that increases of 80 to 100 per cent have taken place.

The local, as well as neighboring, press has recently published articles to the effect that projects were on foot looking to the construction of Pacific cables, in one instance from the United States to the Philippine Islands, and in another from the United States to Japan. Neither report has as yet been confirmed, but it is not unlikely that even rumors of this nature will have a tendency to stiffen the market, not only in view of the considerable quantities of gutta-percha that such an undertaking would require, but as a result of the keen competition that would set in.

Another point to be carefully borne in mind with regard to the production and cost of gutta-percha is the constantly increasing area of land under rubber, cocoanut, and tapioca cultivation. These new estates are well regulated and offer every inducement to the coolie type in the way of compensation and better standards of living. This class of work will, therefore, undoubtedly attract the native and coolie labor away from the jungle, and the clearing of so many tracts of land may mean the diminution of jungle areas and a consequent decrease in jungle products.

Imports and Exports at Singapore

Gutta-percha to the amount of 1,469 long tons, valued at $1,468,792, was imported into Singapore during the year 1918. Of this amount 1,372 tons, at a value of $1,358,764, were imported from the Dutch East Indies, while only 91 tons, valued at $107,431, were imported from British North Borneo, Sarawak, and the Federated Malay States.

Of gutta inferior, 5,243 tons, valued at $518,975, were imported into Singapore during the year 1918, most of which came from Dutch Borneo and Sarawak, Sumatra furnishing only 300 tons.

The following table shows the quantities, values, and countries of destination of gutta-percha and gutta inferior exported from Singapore during 1918:

Gutta-Percha

Countries of destination	Quantity Tons	Value
United Kingdom	1,596	$1,556,357
Canada	138	44,895
France	113	43,909
Italy	30	11,447
Japan	33	22,755
United States	1,230	362,736
Total	3,140	$2,042,099

Gutta Inferior

United Kingdom	99	9,539
Canada	71	6,365
Australia	17	1,797
Other British possessions	1	42
France	10	1,022
Japan	144	16,009
United States	834	89,959
Other foreign countries	2	227
Total	1,178	124,960

Copper Production in Sweden

The Swedish Government Board of Trade states that the production of copper in that country during 1918 amounted to 3,261 tons. Of this amount 4,740,651 lb. was of refined copper, made from "cement copper," valued at 14,542,340 crowns ($3,898,750 at normal rate of exchange); 1,769,570 lb. refined copper made from "bessemer copper," valued at 6,057,258 crowns ($1,626,610); and 12,969 lb. electrolytic copper, valued at 39,957 crowns ($10,712). These values are what may be called factory prices. The production of individual mines cannot for the present be stated.

A New Type of Catalyzer for Hydrogenation*

A Description of a Method of Preparing Finely Divided Nickel Catalyzer by Mechanical Grinding—Scientific Aspects of Abraded Nickel Catalyst—Water-Ground Material Superior

By W. D. RICHARDSON

THIS paper contains a description of mechanically prepared catalyzer for the hydrogenation of oils and for other processes in which metallic catalyzers are used, invented by Benjamin W. Elder, developed by W. B. Allbright of the Allbright-Nell Co., Chicago, and put on a practical operating basis in the writer's laboratory.

This catalyzer differs fundamentally in its method of preparation from catalyzers previously used and is not only of importance in a practical way but is of perhaps even greater scientific importance as a contribution to the theory of catalyzer activity. The process and product are covered by the Elder patents, assigned to the Allbright-Nell Co. of Chicago, Nos. 1,331,903, 1,331,904, 1,331,905 and 1,331,906 of Feb. 24, 1920, and by pending applications.

In March, 1917, there appeared at the laboratory of Swift & Co. a short, stocky, bronze-complexioned man of middle age who was introduced by W. B. Allbright, his companion, as Benjamin W. Elder, recently of Torreon, Mexico. This meeting was the result of previously made arrangements according to which Mr. Elder's process was to be further developed and worked on a practical commercial scale.

Mr. Elder brought with him the simple and primitive appliance which was one of those by which he first proved that an effective and active nickel catalyzer for the hydrogenation of oil could be made by the action of an abrasive upon bulk nickel.

Initial Work on Grinding Nickel

This apparatus consisted of a nickel plate about 12 in. square and $\frac{1}{16}$ in. thick, firmly fixed by screws placed at the corners to a wood block of the same dimensions and $\frac{3}{4}$ in. thick. The other member of his apparatus consisted of a metal sheet or plate measuring about 2 x 2½ x ⅛ in. and screwed to a wooden handle. In order to operate with this apparatus Mr. Elder coated the plate with an oil, such as cottonseed oil, placed thereon a sufficient amount of abrasive, such for example as 200-mesh ground sand or silica, and then, by a process of rubbing the small plate upon the large one with the oil and abrasive between, produced in time finely divided, mechanically prepared, metallic nickel, which upon trial proved to be an active and effective catalyzer for the hydrogenation of oils.

This was not actually the very first apparatus used by Mr. Elder. An earlier one is described in a letter to the writer dated at Los Angeles, April 6, which reads in part as follows:

> It was the unpleasant and dangerous experiences that I had encountered in reducing catalyzers that first made me think of trying to produce "nickel in a finely divided state" mechanically.
>
> Observing closely the oil from a journal bearing encouraged me to give more thought to the subject. I noted that the abraded metal in the waste oil was so fine that it was difficult to thoroughly remove it from my hands.
>
> I finally concluded that what I would really have to do was to design some method of grinding the nickel in the oil that I intended to harden while the oil was hot in a tank that was supplied with hydrogen. I was living in Torreon at that time and Villa was making things so hot that I concluded to get out if possible to the States, but I only got as far as Monterey, where I met a student at one of the colleges, who offered to get me a piece of sheet nickel from the college laboratory.
>
> I finally completed my apparatus, which consisted of a small tank that could be heated externally. In the bottom of the tank I fastened the piece of sheet nickel. Resting on the nickel was a carpenter's oilstone which could be turned by a shaft that passed through the top of the tank. There were the necessary valves for oil and hydrogen, etc. With this crude apparatus I made four or five trials, using about 3 gal. of cottonseed oil before I got things in shape and the apparatus tight. The last trial I made with this apparatus, I think, I had a peon turning the crank that actuated the stone and watching the temperature, while another was attending the gas producer. I think I kept this going three days, as the oil was getting darker each day from the fine nickel that was present, and when the sample of the third day cooked down I was sure that the oil had apparently hardened somewhat.
>
> The next day Carranza attacked the town and my little laboratory was burned down, but several days later I removed some of the wreckage and secured some of the oil from the tank, and then I knew for sure that I had done some work.
>
> Shortly afterward I returned to the States, and it was while I was working for the Allbright-Nell Co. that I mentioned to W. B. Allbright my experiences in trying to produce a nickel catalyzer mechanically. Mr. Allbright offered to finance me if I would continue the line of investigation and I accepted his very kind offer.
>
> After several months trying all kinds of abrasives, I suddenly remembered the black oil from the journal box, and it was not long before I was grinding a mixture of oil and finely ground quartz. After several trials I was sure I was on the right track. I next secured a sheet of nickel about 12 in. square and with a piece of old anode for a rubber or scrubber I was able to produce a catalyzer that would harden cottonseed oil in five or six hours.
>
> During all this time I was greatly encouraged by the cheerfulness of Mr. Allbright, and many very interesting experiments that he suggested were carried out. I think he suggested to me to use an ordinary closed tumbler or tube mill filled with grain nickel, oil and finely ground quartz. In the tumbler we tried out an atmosphere of hydrogen, also carbon dioxide.
>
> There were some features about the catalyzer that we did not fully understand, and at this stage of the game we applied to W. D. Richardson, chief chemist of Swift & Co., to assist in putting on the finishing touches and rounding off the corners that had troubled us so sorely towards the end.
>
> The time I spent with Mr. Richardson and his assistants satisfied me that they were as enthusiastic as Mr. Allbright and myself regarding the possibilities of a mechanically produced catalyzer, and especially was I satisfied that what I had set out to do had been accomplished.

At this point I should like to make a few observations in retrospect upon the Elder process. In the first

*A paper read at the St. Louis meeting of the American Chemical Society, April, 1920, Division of Industrial Chemists and Chemical Engineers, and published by permission of the Society.

place, you will notice that Mr. Elder had the courage of his convictions, which the great majority of chemists have not. We have been talking for years about finely divided nickel and other metals as catalysts, but no one before Mr. Elder had the sagacity and courage to prepare finely divided nickel by the simplest and most practical means. In short, we have all talked about finely divided nickel and finely divided metals as catalysts, but did not produce catalysts in the way suggested by our words, namely, by taking bulk metal and subjecting it to a process which would actually finely divide it in the precise meaning of those words. On the contrary, our so-called finely divided catalyzers have been produced in the past by a reduction in a chemical way of metallic salts, oxides and other compounds.

As a second observation, it appears after Mr. Elder's invention that whenever anyone of us took the trouble to whet his pocket-knife upon an oilstone he produced catalytic material, in this case catalytic iron, and furthermore, that all used lubricating oils which have been used to lubricate the surfaces of iron and more noble metals contain after a period of time finely divided catalytic material, although probably in most cases contaminated by carbon, sulphur and other substances sufficient to reduce the catalytic activity by a considerable amount.

Mr. Elder used the catalytic nickel prepared by him with the simple apparatus I have described to hydrogenize cottonseed oil in a laboratory way. The catalytic material produced in this small apparatus consisted naturally of a suspension of the finely divided metallic catalyst in oil, together with a certain amount of the abrasive. The longer the rubbing or abrading process was continued, the greater would be the relative portion of metal contained in the suspension. If the abrasive action was continued for a short time only, then the abrasive would predominate in the mixture. Mr. Elder also prepared catalyzer in dry form by abrading nickel surfaces with a suitable dry abrasive in the absence of oil. This catalyzer was found to be active, but not as active as catalyzer prepared in oil.

Grinding With Counter Rotating Disks

Naturally the amount of catalyst which could be produced by man power applied to Mr. Elder's first apparatus within a reasonable length of time was very small, and hence Mr. Elder approached Mr. Allbright with the view of making arrangements for working upon a larger scale. With this end in view an apparatus was made consisting of two disks of nickel made to rotate in opposite directions by mechanical means and to the opposed surfaces of which hot oil could be supplied. The friction of one plate upon the other caused finely divided nickel to be rubbed off into the oil and thus catalytic material was produced, but the amount was too small within a reasonable length of time to make this method of production a practical one.

Tube Mill With Nickel Shot

As a further step a cast-iron tumbling mill was then made in which nickel shot was placed, together with a suitable abrasive and oil, and the entire mill rotated until a sufficient amount of catalytic material was obtained. This cast-iron mill was of a special shape designed to give maximum abrasion. It measured about 3 ft. in diameter and was 2 ft. long, measured along the shaft. It was soon found that the cast-iron mill did not produce the most desirable catalyzer for the reason that the abrasive acted not only upon the nickel shot contained in the mill but upon the sides and surfaces of the mill itself to such an extent that the final catalyzer obtained might contain as much as 60 parts of cast iron and carbon derived therefrom to 40 parts of nickel. This was the extent of the development of Mr. Elder's process as carried on by W. B. Allbright working with Mr. Elder in the plant of the Allbright-Nell Co., Chicago. The process was then turned over to the writer for further development in the Swift & Co. laboratories and plant.

After preliminary trials in the laboratory with small porcelain pebble mills, larger tumbling or pebble mills of the Abbé type were installed and these, in order to avoid contamination by iron admixture, were lined with porcelain brick. These mills measured about 5 ft. in diameter by 5 ft. long and were capable of holding a considerable charge of nickel shot.

Several Types of Abrasives Tried

In the laboratory and also in the larger mills all sorts of abrasives were tried—ground quartz of various mesh, ground pumice, carborundum, alundum, diatomaceous earth, etc. It was even found that a first-class catalyzer could be obtained with no abrasive at all, the friction of nickel shot on nickel finally resulting in the production of excellent catalytic material. During the course of the tumbling it was to be expected that a certain amount of the porcelain lining would become abraded and mixed with the catalytic material and abrasive. This admixture was not harmful to the catalytic activity of the finely divided metal, but from time to time the mills had to be relined. No attempt was made to separate the catalytic metal from the admixed abrasive. Many batches of oil were hydrogenized with the catalytic material just as it was removed from the mills and no adverse results were experienced from the presence of the abrasive or abraded mill lining. Mechanical catalyzer was prepared by the Elder process both in the presence of air and of hydrogen and no great practical difference in activity in the two cases resulted.

Since a semi-drying oil was generally used in the mill, any atmospheric oxygen in the mill was usually absorbed by the oil during the course of the run, so that by far the greater portion of the catalytic material was actually prepared in the presence of nitrogen only, in this case. One other method of preparation, namely, by grinding in the presence of water instead of in the presence of oil, was made use of, and this produced a more active catalyzer, as will be described further on after a consideration of the original Elder catalyzer ground in oil.

A Nickel Mill

An ideal mill for the preparation of metallic catalyzer by abrasion would be constructed with a lining of the same kind of metal as the charge and the desired catalyzer. For the preparation of nickel catalyzer, the lining of the mill would consist of nickel plates, preferably of sufficient thickness so that they could be wedged into place against the circular periphery of the mill. The side plates would have to be screwed or bolted on, and if thinner plates were used, these plates would naturally have to be screwed or bolted to the casing at all surfaces. Such a mill would undoubtedly produce a very much larger yield of active catalyzer than a

porcelain-lined mill and would have the further advantage of avoiding additional contamination of silica or silicates from the lining. Although this contamination does not injuriously affect the catalyzer, it necessarily does dilute it beyond the dilution which would be determined by the introduced abrasive alone. The metallic linings would have to be replaced from time to time when they were worn too thin, but there would be no loss of nickel, since the removed plates could be cut into small cubes or melted into shot and reintroduced as a part of the charge.

The Elder Nickel Catalyzer

Under the microscope the Elder catalyzer is seen to consist of minute, opaque metallic particles usually but not invariably characterized by straight line edges and sharp angles. They are of various sizes, depending on the abrasive used and the length of time used in their preparation. Often they appear to be in the form of thin plates and some of them remain unattached, while others clump themselves into groups or lines. The particles have a distinctly metallic appearance as contrasted with the translucent or transparent appearance of some chemically prepared catalyzers of extremely high activity.

In activity the Elder catalyzer ranks very high, and this apparently can be increased indefinitely by long-continued abrasion. It is obvious, however, that there is a practical time limit to the operation and under ordinary operating conditions this cannot with economy be exceeded. It varies according to the type of mill used, the abrasive used, the amount of oil used, etc. It can be made to approach very closely to chemical catalyzer of the highest activity, although it is probable that chemical methods produce somewhat more active catalyzer under practical working conditions than that capable of being produced mechanically. However, it is very much superior to slow-acting chemically prepared metallic catalyzer and to much of the catalyzer that has been used in the past regularly for hydrogenation as well as for other purposes.

Action of Mechanically Prepared Nickel Catalyzer

The action of mechanically prepared nickel catalyzer in the hydrogenation of oils is somewhat different from that of other catalyzers of the same activity. The chemically prepared catalyzers for the most part when introduced into an oil in the presence of hydrogen show almost their highest activity at the start, that is, they may increase in activity by a small amount only, before the activity curve begins to fall. As contrasted with this form of curve, the Elder catalyzer activity curve shows a considerable rise at the commencement of hydrogenation which may last for some time before the curve reaches its peak and begins to decline.

The catalyzer can be used over and over a number of times like other active catalyzer. The usual method of recovery for re-use is by means of filter pressing. In the case of highly refined edible oils, the catalyzer may be recovered and used again for from five to ten or even twenty runs; in the case of lower grade oils, the catalyzer is killed after a much shorter period of use in the same manner as other metallic catalyzers and doubtless by the same means. There always seems to be a noticeable amount of combined sulphur present in dead catalyzers, and without doubt sulphur is one of the active poisoning agents.

The final recovery of the nickel catalyzer made by the Elder process is by means of fusion in a small oil- or gas-fired furnace. The filter pressed catalyzer with its attendant abrasive is first freed of fat by extraction or by burning, then mixed with a suitable flux and introduced into the furnace. The nickel becomes molten and can be recovered in the form of shot by running into water in the usual manner.

The fact that the abraded portions of the bulk nickel or nickel shot consist of catalytic material naturally suggests as a corollary that the abraded surfaces of the nickel shot or bulk nickel itself are also catalytic, and this is the fact. The shot, therefore, after abrasion could be used for hydrogenation in a hydrogenation tower and could be reactivated by the very simple process of removal from the tower and introduction into the abrasion mill.

Simultaneous Grinding and Hydrogenating

Mr. Elder, in one of his patents, describes another ingenious application of his process. He maintains the catalytic material in a state of continued activity by conducting the hydrogenation process in the abrasion mill itself. Under such circumstances a continuous supply of active catalytic material is afforded and the activity of the catlyzer therefore cannot run down. The rate of chemical action is limited only according to the law of mass action and not by the poisoning of the catalyzer. I do not mean to suggest by this that poisoning does not occur, but only that it is not effective, inasmuch as a fresh supply of active catalytic material is continuously furnished.

Scientific Aspects of Abraded Nickel Catalyst

The type of catalyzer which I have described is not only of the greatest interest and importance in a practical way for the hydrogenation of oils and for other industrial catalytic reactions, but may be considered perhaps even more important for the theory of catalysis. That theory, particularly wherein it deals with metallic catalyzers, has emphasized the fact that the catalytic action was a surface action and presumably proportionally to the total surface of the catalytic metal or metal particles. Nevertheless, in the past metallic catalysts have been made universally by chemical means and while it was known that when working by reduction processes metallic catalysts in a very fine state of subdivision were obtained, the extent of the surface was to a large degree beyond control and it would have been difficult working by chemical means to obtain catalysts consisting of graded particles of different sizes and with different ratios of surface to mass. By the abrasion method catalysts of every degree of activity can readily be obtained from coarse, slowly acting catalysts to those of the utmost fineness, surface extension and activity.

Another point of the greatest interest is the fact that when the abrasion method is used there can be no doubt about the metallic character of the product. In the case of nickel catalyzer designed for hydrogenation and prepared by the chemical methods, it has been claimed by one school of theorists that the active particles do not consists of metallic nickel but of a sub oxide of nickel and that in the true metallic condition finely divided nickel is unsuited for the purpose of hydrogenation.

The abrasion method for preparing nickel catalyst

proves beyond question that finely divided metallic nickel obtained from bulk nickel by purely mechanical means is an active catalyst for the hydrogenation of oils and other hydrogenation reactions. The nickel particles so prepared (as described above) are decidedly opaque and metallic in appearance under the microscope. They also become decidedly magnetic when placed in a magnetic field and thereafter tend to group themselves end to end in chains as might be expected, while, under the influence of a bar or horseshoe magnet, the particles group themselves along the Faraday lines of force as do iron filings.

Effect of Temperature on the Activity of Metallic Catalyzer

The statement has been made and reiterated in the chemical literature that nickel catalyst must be prepared at a low temperature to be active, the temperature favored for the reduction of nickel oxide, for example, being about 300 deg. C. and preferably lower if effective reduction conditions can be maintained at a lower temperature. The facts in the case of chemically prepared reduced catalyzer are well established. If high temperatures are used for the production of such catalyzer, an inactive product is obtained, but the underlying assumption that heat treatment in and of itself must of necessity produce an inactive catalyst appears unwarranted in the light shed by Mr. Elder's discovery. The nickel shot or the nickel plates used for the production of this catalyst have been subjected to a temperature above the melting point of nickel, let us say above 1,470 deg. C. All of the catalyzer particles have been heated to this temperature, but it has not had the effect of deadening their activity. Our views, therefore, in regard to the effect of high temperatures on metallic catalyzers will have to be modified in conformity with these new facts established by mechanically prepared metallic catalysts.

Water-Ground Catalyst More Effective

I should like to conclude my paper at this point, having shown definitely and conclusively that nickel catalyzer prepared by the abrasion process and in the metallic condition and having been subjected to a high temperature is a decidedly active catalyst, but as a matter of fact, working in our laboratory and plant on the development of mechanically prepared catalysts, we were able to produce a still more effective catalyst by substituting water in the abrasion mill for oil. Catalyzer prepared in the presence of water has the disadvantage of necessitating the removal of the water and the substitution of oil therefor prior to the introduction of the catalyst into the hydrogenation apparatus or converter. This, however, was not especially difficult or expensive. The catalyzer produced in the presence of water was definitely, decidedly and invariably more active than that prepared by grinding in oil. Various explanations for this increased activity may be assumed:

1. That in the presence of water the abrading action produced a more finely divided catalyst.

2. That there would not likely be any catalyzer poisons in the water which might on the other hand be present in any oil produced.

3. That by grinding in water and in the presence of air a film of sub-oxide is formed on the catalyzer particles.

The last explanation may be the true one[1] and if so we are once more confronted with the importance of the sub-oxide theory and forced to conclude (if this explanation is correct) that while nickel in the metallic condition will catalyze hydrogenation reactions, nickel coated with a sub-oxide layer will catalyze at a still more active rate. However, a comparison should be made at this point between mechanical catalyzer prepared in water and by dry abrasive in air with no fluid medium present. In the last-mentioned case an active catalyzer was produced, but one much less active than the two other types mentioned. Apparently, therefore, too much oxidation during preparation is injurious, and if a sub-oxide film increases the activity of nickel catalyzer, this film must be kept within the narrowest limits if the most active type of catalyst is desired.

Sub-Oxide Theory

In considering the sub-oxide or oxygen-layer theory, it should be remembered and emphasized that we are dealing with a hyrogen reaction and that to bring this reaction about, the catalyst, whether nickel or palladium or other metal, must have, or does have, large volumes of hydrogen occluded on its surface and below the surface. It is difficult to believe that any oxygen or oxide could long persist under this condition and at the relatively high temperature employed in hydrogenation, but on the other hand, the reduction of the oxide or oxygen-layer might result in an increase of surface by roughening or furrowing, and if this hypothesis is correct, metallic nickel would still be the active agent, a larger surface having been obtained by alternate oxidation and reduction. Again, the oxygen might have the effect of offsetting the influence of certain poisons such as sulphur (sulphides), which when exposed would not again be reduced under the conditions of the reaction, as is well known. Sulphates, such as calcium sulphate, sodium sulphate, nickel sulphate, etc., have been found to be quite without adverse effect or any effect at all in the hydrogenation of oils.

Conclusion

In this paper I have not attempted to give a complete exposition of the preparation of metallic catalyzers by mechanical means, but only to touch upon the more important points. They are comparatively new in industry and have not as yet had the widest use. They must commend themselves for the simplicity, certainty and directness of their preparation and for their necessary uniformity. They will undoubtedly prove useful in developing the theory of catalytic activity.

In conclusion, acknowledgment is made to Paul Escher and G. W. Phelps of the Swift & Co. laboratory force for assistance in developing the catalyzer.

Sheffield Uses Films to Push Steel Trade

Sheffield, the great center of British engineering, is utilizing the film to promote the British steel industry and to develop British export trade in steel products.

A series of films will be shown this year in eighty-six of the principal cities of western Europe, America and the British colonies, which, experts consider, will be a fine advertisement.

Volatilization in Assaying*

Losses Often Ascribed to Volatilization Caused by Excessive Temperatures Are Usually Due to Dusting and Other Mechanical Causes—A Review of the Literature Published on Losses Due to Volatilization for Gold, Silver, Lead

BY FREDERIC P. DEWEY†

IT IS common to blame irregular assay results upon volatilization, and much has been written upon the subject, but there is no real evidence that in a properly conducted assay, the loss of either gold or silver by volatilization is sufficient to affect appreciably the result, even when arsenic or antimony may be present. Bulk assays of flue dust from assay muffles have been published, but the data given are totally insufficient to even approximate the volatilization from a single assay; and such figures as we have indicate the volatilization to be extremely small. Diligent search in the literature and wide inquiry among assayers and instructors have failed to produce a single case where the litharge volatilized in making an assay has been collected and assayed for gold and silver. Having attempted to do this, with most indifferent success, I am not surprised that this has not been done.

While various textbooks give volatilization as a cause of loss in cupellation, it may safely be said that in the rare cases where the volatilization is sufficient to affect appreciably the result it is due to excessive temperature. Percy[1] says, "The loss of silver by volatilization during cupellation is very slight (unless the temperature has been much too high), and may be disregarded." This statement is repeated by the Beringers[2] and Smith,[3] who include gold and silver. Mitchell[4] says that litharge fume rarely contains over one ten-thousandth of silver. Campredon[5] says that at a proper temperature no silver is lost by volatilization.

Primarily, excessive temperatures may be due to too high general temperature in the muffle; but it may often be due to temperature localized within the bead by oxidation of the metals, and this may be influenced by other causes than the general temperature. I have shown an extreme case of local temperature,[6] resulting in the burning of zinc with its characteristic flame and variations in bead temperatures with uniform pyrometer readings. Volatilization from a bath of mixed metals is not the simple question of vapor pressures of the contained metals. Based entirely upon vapor pressures, Richards,[7] in speaking of the distillation of zinc from Parkes crust, says, "Successively larger amounts of lead, silver and gold come over the higher the temperatures," but I have shown that more silver goes with the zinc in the early stages of the operation than later.

The possible volatilization of the precious metals in cupelling is the most complex proposition. It may be due to the vapor pressure of the individual metals, the vapor pressure of alloys or possible metallic compounds, of compounds of metals with metalloids or with non-metals, particularly oxygen. Also it is not possible to draw a sharp line between true volatilization due to vapor pressure and the drag of a volatilizing body exerted upon a less volatile associate, against which is the counter-drag, or stabilizing effect, of the non-volatile upon the more volatile, all of which are influenced by concentration and association. The temperature conditions of the cupelling beads vary constantly, which may change any or all of these conditions. The oxygen supply influences them. Even more important, perhaps, is the extent to which the surface of the metal is covered and protected by the litharge formed. At moderate heats much of the button surface is covered by the litharge and the opportunity for direct volatilization of the metals reduced. Intimately connected with this is the question of secondary volatilization, oxide of lead being volatile, oxide of silver may be dragged along, even if it is not covolatile. No one knows how much, if any, of the lead, or any other metal, present in cupel fumes volatilized before oxidation.

Rose[9] suggests that gold and copper go off as "vaporized alloy" and Mitchell[10] says silver is much more volatile when alloyed with lead. Wright[11] bessemerized silver bullion high in arsenic and the arsenious oxide produced showed about 800 oz. silver per ton. I have roasted rich arsenide ores[12] at a very low temperature and the arsenious oxide given off showed only a few ounces of silver per ton. Mitchell[13] says the litharge fume in cupelling is "produced by the vapor of lead burning in the atmosphere," but gives no data.

Again, other questions of molecular physics are involved. Keller[14] has shown that gold travels into copper on prolonged heating of the alloy below its melting point. So the rate at which the precious metals withdrawn into the cupelling bead must affect the drag. Gillett[15] says that on heating brass, loss of zinc depends, in part, "on the rate of diffusion of zinc from the body of the melt into the surface that is losing zinc."

LOSS THROUGH DUSTING

Many statements regarding volatilization in assaying are based upon data obtained under conditions entirely different from cupelling, and much that has been written

fails to distinguish between volatilization and dusting, which is purely mechanical. In practical operations, losses are often ascribed to volatilization that are largely, if not entirely, due to dusting and other mechanical causes.

In modern practical work, there is now probably very little straight cupellation of lead. Where works have lead rich enough to cupel, advantage is generally taken of this to work up other high-grade products, rich ores, slimes, etc. Much of the extremely rich silver ore from Cobalt, Ont., has been treated in this way. These additions, particularly very fine slimes, favor dusting and high silver in fume or dust collected from cupelling furnaces does not prove high volatilization. Iles[16] gives many figures on fumes and dusts from various sources. A mixed cupel fume showed 85.90 oz. silver per ton; this might indicate volatilization, but the fact that it was only 72.50 per cent lead showed dusting, oxide of lead containing 92.83 per cent lead.

Mr. Dieffenbach[17] has furnished a month's record of the results from the Cottrell condensers on the cupel furnaces. The fume collected weighed 24,659 lb. and contained 9,863 lb. lead, or approximately 40 per cent, indicating much dust. This is accounted for by the fact that about 70 tons of slimes was treated on the lead bath. The fume contained 5,830.11 oz. silver, or 0.64 per cent of the silver charged. In view of so much mechanical dusting of rich stuff, the actual volatilization must have been very small. The slimes charged contained nearly 555,000 oz. silver. In a negative way, the figures show that there was practically no volatilization of gold, for notwithstanding the dusting, only 12.07 oz. gold was found in the fume out of 16,855 oz. charged, of which over 13,000 oz. was in the slimes.

Condensation of Assay Muffle Fumes

Various persons have reported the finding of gold and silver in the fumes condensed in the flues of muffles, but these generally show only minute quantities of the precious metals and all lack quantitative significance. Smoot[18] says, "We assayed the condensed fumes from the muffle ventilation pipe and found only a very small amount of silver and practically no gold," and "This seems to indicate, in a qualitative way, that only a negligible amount of silver is lost in the lead fume."

The best figures that I know of regarding the condensation of assay muffle fumes have been supplied by Donald M. Liddell. One muffle was used only in pig copper assay by the combination method. It carried very close to 90 oz. per ton, and the residue from one assay-ton, after burning off the paper, was scorified with one assay-ton lead down to about 7 g., which was cupelled in the same muffle. The muffle had a small forced-draft apparatus at the back and all fume passed through an iron pipe, which formed a fairly efficient condenser. This pipe was cleaned out every six months, during which time about 5,500 assays were made, yielding about 175 g. of litharge. One lot of 175 g. gave 142.7 mg. silver, but not enough gold to weigh. This would roughly mean the volatilization of about 0.026 mg. silver per assay, or approximately 0.03 per cent. It would seem fair to divide this between the scorification and cupelling, estimating the cupel volatilization as 0.015 per cent.

[17] Superintendent of the Balbach Smelting & Refining Co., Newark, N. J.
[18] Personal letter.

Johnston[19] has published a most valuable review on the vapor pressure and volatility of several high boiling-point metals, giving many references, particularly of exact scientific investigations. The ultimate object of this paper was to devise a formula for determining the approximate volatility of various metals at different temperatures. The data regarding gold, however, were too scanty for this. There is absolutely no connection between melting point, vapor pressure, and boiling point. Various metals show vapor pressure below their melting point. Tin, with a melting point of 232 deg., is said to boil at about 2,300 deg., while copper, with a melting point of 1,083 deg., is said to boil about 100 deg. above tin.

Volatility of Gold

Varied statements have been made regarding the volatility of gold. Gmelin[20] says, "It exhibits a scarcely perceptible volatility at the strongest heat of a blast furnace, in the focus of a burning mirror, and in a flame fed with oxygen gas." Napier[21] appears to have been the first to make systematic tests and is often quoted, but his figures are small, about 0.1 per cent, and the time of heating long, 3 to 8 hr. Makins[22] is often quoted, but his figures are extremely small, even though an extraordinary heat was used in the cupellations; there is no connection with the amount of gold operated on; he simply found 0.087 g. of gold in 1,000 g. of flue dust. The volatility of gold before the extreme heat of the blowpipe is described in Crookes.[23]

Seamon and Parker[24] heated beads of gold, 1 to 20 mg., varying periods of time, to temperatures from 1,000 to 1,650 deg. Losses were observed only twice and were attributed to unobserved errors of manipulation. Under the conditions of a cathode-ray vacuum, on prolonged heating, Krafft and Bergfeld[25] were able to observe volatilization of gold at 1,070 deg. Moissan[26] places the boiling point at 2,530 deg. Mostowitch and Pletneff[27] state that in oxygen, nitrogen, carbon monoxide, and carbon dioxide at 1,400 deg. volatilization is not appreciable, but is noticeable at 1,250 deg. in hydrogen. Kern and Heimrod[28] made extensive tests on the volatility of gold and silver, obtaining some interesting results, but their conditions were quite different from cupellation. Many hours heating in contact with carbon did not volatilize silver from copper, but did volatilize gold from copper, possibly by the formation of a carbide of gold. Incidentally, their quotation from Napier is faulty. Wurtz[29] gives a review of early information.

T. K. Rose has been a prolific investigator of this subject and his books and papers contain many references. In 1893 he stated[30] that volatilization of gold begins just below 1,100 deg. and at 1,250 deg. the loss per min. was four times as great as at 1,100 deg., the loss on a charge of 1,200 oz. was figured to be 0.02 per cent per hr.; the volatilization in cupellation was insignificant. Later he says[31] that the loss in an ordinary melting furnace is

seldom over 0.01 per cent on 1,200 oz. and is influenced by temperature, metal surface exposed, and time, and is increased by air passing over the metal and by impurities. Still later[32] he says, "True volatilization of gold is so small as to be negligible at the temperature of industrial melting furnaces, say 1,000 to 1,300 deg. It is difficult to measure with accuracy the infinitesimal amounts volatilized at these temperatures." "Even in a strong draft the amount volatilized remains exceedingly small" provided the nature of the gas does not change. Alloys, however, may take up and eject gases with spurting, which may give globules less than 0.001 mm. in diameter, which may be carried away by even a slight draft and are difficult to recover. The first table of results, p. 4, is an excellent illustration of a fact I have often met in the literature and in my own experience with gold; that is, the effect of unrecognized conditions leading to erratic results when expecting regularity.

In a paper on accuracy in assaying, Rose[33] attempted to follow the course of the gold and gives results from which he concludes that while final loss is shown in each case it does not represent the amount volatilized with certainty, errors of five determinations being accumulated here. I would add that he determined the silver and other metals left in his cornets in a lump by a reassay, which must have been subject to all the errors of the original assay.

Hillebrand and Allen[34] give some figures upon volatilization, but they exhibit serious irregularities. On gold alone two cupel recoveries exceeded the total loss and the volatilization figure on No. 4 cupel was more than twice No. 6, two cupels behind. In series B, Table IX, 15 mg. gold, 45 mg. silver, No. 3 showed a higher figure for gold volatilization than No. 6, three cupels behind it in the furnace, and on silver No. 4 showed more than No. 6. While the total losses show considerable regularity from front to back of the furnace, the ratios between volatilization and absorption are erratic. The possibility of losing gold mechanically in decanting and washing was not provided for in the volatilization tests.

Schneider[35] attempted to determine volatilization by cupelling 450 mg. gold, 50 mg. copper, 1,200 mg. silver, 4 g. lead, recupelling the resulting bead with 4 g. lead and repeating eight times. When properly carried out, this method might give a good approximate, but Schneider generalized as to some of his figures and assumed that no gold went into his nitric acid, although he assayed the ten cupels for gold and silver absorbed.

I have done considerable work in trying to arrive at a figure on volatilization of gold in cupellation by the examination of the products of the operation. No determination of volatilization depending in any way on the weight alone of a bead or cornet can be convincing. The normal bead is never pure precious metal. Cornets always carry silver and copper and often lead. Gold goes into the parting acid and into the cupel. After actually determining these items and balancing the results, we get a figure which might be called volatilization, but it is a different figure and bears the errors, both plus and minus, of much analytical work; therefore it must be handled with judgment. Sometimes the figure indicates an appreciable loss; sometimes it gives practically a balance, indicating no loss; a gain also has been shown.

All these points are shown in one test. The San Francisco mint prepared an ingot of standard gold, 900 gold 100 copper, for test purposes. It was extremely close to 900 fine in gold. Three sets of nine assays, three rows of three, were run at three temperatures, the regular heat for this work, very low, and very high. The regular heat showed a slight loss of gold. The very low heat showed a gain. The very high heat, which should have favored volatilization of the gold, gave practically a balance, the figures showing a loss of only 0.005 mg. for the set. The figures are as follows:

	Regular Heat, Mg.	Very Low Heat, Mg	Very High Heat, Mg
Silver in cornets	3 51	3 55	3 02
Copper in cornets	0 31	0 23	0 32
Lead in cornets	trace	trace	trace
Total in cornets	3 82	3 78	3 34
Cornet weight	1 575+	2 35+	2 425–
Gold lacking	2 445	1 23	5 765
Gold from solution	0 125	0 20	0 200
Gold from cupels	2 14	1 49	5 56
Balance	0 18	0 46+	0 005–

From these figures it is evident that there is no necessity for running coin gold, and by fair inference fine gold, at such a heat as to favor the volatilizing of gold during cupellation. The high loss of weight of the cornets at the very high temperature could not be tolerated as a regular practice and such a temperature would not be used regularly.

Volatility of Silver

Silver is far more volatile than gold. Gmelin[36] states that it boils by the burning mirror when it rises in white fumes and that it volatilizes in an open crucible at incipient white heat, but not if covered with charcoal dust. In a cathode-ray vacuum, Krafft and Bergfeld[37] observed volatilization at 680 deg. Johnston[38] gives its melting point at 960 deg. and its boiling point at 2,090 deg. He calculates that it has a vapor pressure of 10^{-3} mm. at 920 deg. and 1 mm. at 1,320 deg. In his atomic-weight work, Stas[39] distilled silver to purify it.

Richards[40] proposed to separate silver from blowpipe beads by volatilization. Over 95 per cent of the silver was to be removed by heating before a sharp-pointed oxidizing flame to 1,100-1,200 deg. estimated and the balance removed at about 1,500 deg. estimated, at which temperature the gold begins to volatilize. In a subsequent paper,[41] on measuring buttons, he said, "It is difficult to drive off all the silver, as the last 5 to 10 per cent volatilize slowly and probably also take a little gold with them," furnishing an excellent illustration of the drag of a volatilizing metal upon a less volatile associate as well as the stabilizing effect of a less volatile metal upon a volatilizing one.

In a little-known and short-lived journal,[42] Seamon and Parker describe extensive tests on cupellation. As a preliminary, they made many tests on beads of silver 999 fine, of various weights up to 80 mg., for various times up to 4 hr., at various temperatures 900 to 1,600 deg., by simply heating them in cupels. At the conclusion of the heating all the cupels showed a brownish spot

below the beads. Several cupels were tested qualitatively for silver, which was always found. They proposed to make qualitative determinations of the silver absorbed, but I have not found such results published. The results are somewhat irregular. In one set of eight, on beads 5.09 to 22.50 mg., at 900 deg. to 1,000 deg. for one-half hr., each one showed a loss of 0.02 to 0.07 mg., while another set of six, 20 to 80.06 mg., at the same temperature for 1 hr., showed no losses. They conclude that at 1,000 deg. "the loss appears to be mainly due to the oxidation of the silver and absorption of the oxide by the cupel," but at high temperatures volatilization may become important. Under their conditions 960 to 1,020 deg. barely gave feathers in cupellation.

I have done much work in checking up and extending this line of tests. Seamon and Parker appear to consider 999 silver as entirely satisfactory, but it is far from being pure and the impurity might influence the result. I used five grades of silver: proof of the highest purity, parting silver of high grade but not up to proof, ordinary silver reduced from the chloride by zinc, 50 g. parting silver melted with 50 mg. lead, 50 g. parting silver melted with 50 mg. copper. Under small beads it was only with the copper sample that the stain was plainly visible. With large beads four of the silvers stained the cupel and sometimes adhered closely to it: parting silver was not tested on large beads. Both large and small beads often showed a white coating. The figures showed irregularities and were larger than Seamon and Parker found, but I was forced to the conclusion that it was futile to expect to obtain exact or even comparative figures and discontinued the tests.

Exposure of molten silver to the air leads to a mixed result. There is oxidation of the silver and maybe volatilization. The oxidation products may be absorbed by the support in part only and part may remain in or on the metal. The loss shown by weighing the silver before and after such exposure cannot lead to definite results on any point.

Relations of Silver and Oxygen

Many and most contradictory statements have been made regarding the relations of silver and oxygen, both chemical and physical. The subject is greatly in need of clarification. It is apparent that they unite in various proportions.[43] While Ag_2O loses oxygen at very low temperatures and is said to be entirely decomposed[44] below 350 deg., pure silver prepared in the ordinary way gave off oxygen at 400 to 500 deg. for 6 hr. at the rate of 57 c.c. for a kilo of silver.[45] Silver and oxygen certainly combine at much higher temperatures and separate on lowering the heat.[46] Watts[47] says there is an oxide of silver volatile at high temperatures. Possibly this is based upon Plattner,[48] whose statements are questioned by Percy[49] and were further investigated by Christy.[50] Wartenberg[51] found silver appreciably more volatile in oxygen than in nitrogen and attributes this to the formation of silver oxide at high temperature, which may then possibly exist as a gas owing to its high heat of vaporization. Various writers have stated that sublimed silver often contains oxide of silver. Troost and Hautfeuille[52] say protoxide of silver exists in the very hot gases. Gmelin says, "Silver at a white heat decomposes aqueous vapor . . . taking up oxygen," but on the next page says, "Silver does not oxidize in dry or moist air at any temperature below its boiling point." He also says silver "is less oxidized than platinum by fusion in the air."

T. K. Rose[53] says, "Even platinum was much more readily oxidized than silver," but in a previous paper[54] on refining by blowing air through molten bullion and fluxing the oxides produced he brought bullion 354 fine in gold and 621 fine in silver up to 885 gold and 103 silver. In comparing his process with cupellation, he says, "Later, when the percentage of silver is high, it is freely oxidized in both processes, and the oxidation is at its maximum when the silver is practically pure." He says the "whole trend" of his work "is to show that it is silver that carries oxygen to base metals" and does not consider base metals oxygen carriers to silver. In this he appears to be dominated by theoretical considerations regarding normal oxides, Ag_2O and PbO for instance, and to overlook the possible interaction of other oxides.

The well-known spitting of silver in solidifying has been generally assigned to the evolution of oxygen, but it has also been ascribed to the compression[55] of the solid crust on the molten interior. Having cooled large buttons, 7 to 10 g., with extreme slowness and having obtained projections in the general form of a large irregular, inverted, hollow cone, in some instances only one cone on a button, I am satisfied that compression contributes to the spitting of solidifying silver. I have also produced spitting by the sudden cooling of a bead by contact with a mass of cold iron. In this connection it is certainly significant that silver melts and solidifies at a lower temperature in oxygen than in a reducing atmosphere.[56] Aside then from the natural cooling and solidifying of the surface first, the interior retains a lower melting point and remains liquid longer than the exterior, which has lost oxygen with the consequent raising of the melting point. The non-spitting of silver containing other metals may be due to changed differentials in the melting points.

Volatility of Lead

Johnston[57] gives the boiling point of lead as 1,640 deg. and the vapor pressure as 1 mm. at 960 deg. Krafft and Bergfeld[58] give 335 deg. as their lowest observation of volatilization of lead in a cathode ray vacuum. Schuller[59] and Kahlbaum, Roth and Siedler[60] distilled lead *in vacuo*, and the latter obtained a crystalline product. Roberts[61] showed that with proper care there was no appreciable volatilization of lead in melting assay samples of base bullion. From the distillation of alloys, Moissan and Watanabe[62] announced that the order of distillation is lead, silver, copper, tin. The litharge cloud

that is given off during cupellation is very deceptive. It makes an impressive showing in the muffle, but the actual weight of oxide of lead is slight.

More than fifty years ago Mitchell[63] announced that in the ore-assay cupellation "not more than 2 to 3 per cent of lead is volatilized"; I have abundantly verified this statement. By weighing the cupels before and after use, I have found that it is quite possible to run an ordinary 20-g. button with the volatilization of about 0.5 g. of lead. This, however, involves some risk of freezing and requires much attention. At only a slightly higher temperature, with an increase of the volatilization to 0.75 g., there is no risk of freezing and the operator may simultaneously look after other things. When the volatilization rises to 1 g. there is but slight feathering unless special condensing arrangements are used. In one test, three cupels of the front row showed less than 2.75 per cent volatilized and the fourth froze, while the second row of four showed from 5.5— to 6— per cent volatilized and there were few feathers. With larger buttons, 50 to 60 g., seven cupels showed less than 2 per cent volatilized, with a minimum of 1.4 per cent. In the cupellation of bullion,[64] where necessarily a higher temperature is used, the volatilized lead should not exceed 10 per cent.

Most contradictory statements have been made regarding the volatility of oxide of lead. The assayers' daily experiences disprove the statements of various textbooks as to its volatilizing only at a high temperature. The books appear often to be speaking of boiling[65] rather than simple volatilization. However, the boiling point, 870 deg., given by Mott[66] is palpably much too low. Doeltz and Grauman[67] say volatilization was slight at 800 deg., increased rapidly to 900 deg., when it became liquid, not so rapidly to 950 deg. and was not tested above 1,000 deg. By changing the ratio of surface to mass, they varied the loss from 8.8 to 0.04 per cent at 900 deg.

Feathering as an Indication of Temperature Conditions

Feathering is not always a sure indication of the temperature conditions of the bead. With high bead temperature and an abundant air supply the cupel may show good feathers, while the same bead temperature with limited air supply would not. Lack of feathers, particularly on inside cupels, may be due to lack of cooling conditions above the cupel, instead of high bead temperature. In two well-feathered cupels, Hillebrand and Allen[68] found 0.05 mg. loss of gold on 10.67 mg. cupelled, but only 0.03 mg. on 15.56 mg. The cupels immediately behind these showed 0.06 and 0.17 mg. losses, respectively. It is possible that lack of feathers may also be due to a leaky muffle.

Effect of Other Metals on Volatilizing of Gold and Silver

When true volatilization occurs in quantity, the volatilizing metal exerts a drag upon its less volatile associates, but the real data upon the subject indicate that in the vast majority of cases this drag is but slight. Bodemann and Kerl[69] say silver is often disposed to volatilization by arsenic, antimony, zinc and lead.

T. K. Rose[70] says that the presence of zinc, arsenic, antimony and other volatile metals is believed to greatly increase the volatilization of gold, but gives no data. Hellot[71] says an alloy of one part gold and seven parts zinc volatilizes completely at a high heat, but Friedrich[72] investigated the subject and reported fifteen tests, from which he concluded that the loss was mainly due to mechanical action and it is only with rapid volatilization of zinc that the gold volatilization becomes appreciable. Up to 1,500 deg., the loss was so slight as to warrant the conclusion that zinc has no influence in promoting the volatilization of gold below this temperature. I have shown[73] that in distilling the zinc out of Parkes crusts, very little silver goes over in proper work and that volatilizing lead carries but slight amounts of silver. I have also shown[74] that irregular assay results may be due to zinc carrying the precious metals to the surface of the cupel. It may well be that arsenic and antimony cause irregular assays in the same way rather than by volatilization. I have shown, too, that[75] the roasting of rich arsenide ores at a low heat produced arsenious oxide practically free from silver. In some recent tests we have obtained much more concordant results than those reported on arsenical bullion.[76] The assays were run in sets of six, two rows of three cupels with proofs in the center; two sets were run on 5 g. lead and one on 8 g. on each bullion. The results were:

No. 1		No. 2	
Gold	Assays	Gold	Assays
665.5 fine	1	811.3 fine	1
665.6 fine	2	811.4 fine	2
665.7 fine	4	811.5 fine	3
665.8 fine	4	811.6 fine	1
665.9 fine	6	811.7 fine	3
666.1 fine	1	811.8 fine	5
		812.0 fine	3
	18		18

The arsenic in No. 1 was high but unknown, in No. 2 it was about 10 fine with, approximately, 90 each of silver and copper.

It is often claimed that tellurium promotes volatilization in cupellation, but T. K. Rose[77] carried on an extensive series of tests under many conditions and in only one was gold found in the condensed tellurium. Holloway and Pearse[78] say, "Loss by direct volatilization is very slight under proper conditions of working," and on cupelling beads containing tellurium with proofs without tellurium in side by side cupels some tellurium beads lost less than the proofs.

In retorting gold amalgam, Rose[79] states that about one grain of gold goes over per lb. of mercury. Although outside the scope of this paper, it may be mentioned that the recent volumes of *Transactions* of the American Electrochemical Society contain much interesting information regarding the action of metals, alone or mixed, at the very high temperature of the electric arc; and in 1907, Watts reviewed the work of Moissan.

Determination of Silver by Cupellation

The method I used in following up the course of the gold in a bullion assay is not applicable to silver. The determination of silver by cupellation[80] is quite unreliable and with large amounts the absorption of silver by

[63] *Op. cit.*, p. 484. Tests are given by Lodge: "Notes on Assaying," p. 56, and Liddell, *Eng. and Mining J.* (1910), vol. 89, p. 1,264.

the cupel[81] is most erratic. On the other hand the determination of the base metals left in small beads is unsatisfactory unless we have an exceedingly large number of identical beads. In another connection, I have shown[82] that the straight assay of a silver bullion showed 987 fine, which corrected for the cupel absorption became 998.5 fine, while cupellation with proof showed 999.3 fine. Liddell[83] gives some very interesting tests on cupellation, but he determined the "fineness" of his beads, and this was subject to the errors of the original assay. Both these tests lack conclusiveness.

L. Campredon's book[84] says that all the silver lost is absorbed by the cupel, but the tests lack the determination of base metals in the beads. G. Campredon[85] made three tests in duplicate at a high temperature, one set using five times as much copper as silver, but he made no examination of his buttons. His result varied from nothing to 2.10 per cent on 100 mg. silver. He made two assays of his cupels; one for beads on the surface, which varied from 0.40 to 1.50 per cent, and one for absorption. Various other indirect tests have been made, but all lack important data. Some tests show a gain even when the recoveries of silver were not complete.

It remains then that the only way to determine the volatilization of silver in a cupellation is to collect the litharge volatilized and assay it for silver. Manifestly this is also the only real way to ascertain the volatilization of gold under assaying conditions. I started out to do this without interfering with the normal conditions of cupellation, but found it impossible to do so in an ordinary muffle in constant use for regular work. Various arrangements of temporary baffle plates proved inefficient condensers and in many cases the condensed litharge entered into combination with the plate material. While it is possible by the use of special cooling arrangements to grow a large crop of feathers on the cupel, once the fume got out of the cupel it was practically impossible to stop it. Of course with a small muffle provided with special condensing flues, such as a Cottrell tube, and running a large number of identical assays a good approximation may be obtained, but I did not have these conditions. Again, with the low rate of volatilization of the lead in a proper cupellation of an ordinary 20- to 30-g. button, the best feather-growing arrangements will yield only insignificant amounts of litharge. Feathers are most deceptive; they bulk large but weigh light.

After various tests I made a very deep cupel with straight sides. In the early tests the condensation of litharge was erratic, varying from 0.2 to 1 g. and considerable experimenting was required to develop a satisfactory procedure. With 100 g. lead and 1 g. silver 0.605 g. litharge condensed, yielding 0.055 mg. silver; with 5 g. silver 0.735 g. litharge gave 0.26 mg. silver; with 133 g. lead and 6 g. silver, 0.97 g. litharge gave 0.26 g. silver; with 140 g. lead, 2.11 g. copper, 8.33 g. silver, 0.465 g. litharge gave 0.27 mg. silver. By using large amounts of lead, placing the cupel close to the front of the muffle and filling in around it so as to force all the draft over the cupel, and by protecting the cupel from radiation from the muffle top, I was able to condense a gram or more of litharge for assaying. This is none too much, even when cupelling very rich lead.

A most serious objection to this method is that in time the surface of the bullion sinks out of sight. As one cannot see the end of the cupellation, careful watching and much judgment is required in turning off the gas. In ten tests, six buttons weighed more than the silver taken, the maximum being 3.4 g. on 1 g. taken and the minimum 0.13 on 5 g. taken. Of the four losses, the maximum was 0.46 on 5.81 g. and the minimum 0.04 on 5.045 g.

In general, 140 g. of lead was taken, the smallest amount of gold used alone was 140 mg., which would correspond to 20 oz. per ton in a 20-g. button from an assay-ton fusion. The largest was 1.4 g., or 200 oz. per ton. The following results were obtained. In the last test only 105 g. of the lead was oxidized.

Gold Taken, g.	Litharge Recovered, g.
1.40	1.45 containing 0.09 mg. gold
1.40	1.176 containing 0.02 mg. gold
0.70	0.876 containing 0.01– mg. gold
0.140	1.213 containing trace
0.140	0.725 containing speck

A sample of the celebrated Mercur bullion, about 884 fine in gold and less than 8 fine in silver, 1.6 g. yielded 1,185 g. litharge containing 0.03— mg. gold. Samples of miscellaneous bullion, most of them presenting unusual difficulties in ordinary assay work, yielded the following results:

Bullion weight, Grams	Fineness		Recovered		
	Gold	Silver	Litharge Grams	Gold, Mg.	Silver, Mg.
3.5	808	34	0.92	None	Slight trace
2.5	585	95	1.45	Speck	0.02
2.5	585	316.5	1.312	Very slight trace	0.015
4.0	361	228.5	1.32	0.01	0.08
4.2	343.5	443	1.13	0.005	0.16
6.75	211	225	0.95	0.005	1.26

In the last test, a scum appeared early and crystals were slow in forming; probably some of the scum adhered to the feathers recovered.

With 1 per cent, 1.4 g., gold, and 3 per cent, 4.2 g., silver, 1.27 g. feathers showed a very slight trace of gold and 0.21 mg. silver. In one test the lead carried about 1 per cent arsenic, but the cupel cracked. With 0.5 per cent arsenic and 1.4 g. gold, 1 g. litharge was collected and the gold obtained was estimated at 0.002 mg.

Three grades of base bullion were tested—good, bad, and very bad for assaying. Using 159.5 g. of the first gave a button weighing 1.24 g., 0.762 g. litharge was collected, which gave a bead of 0.08 mg. The second would not cupel direct, but 20.03 g. was run with 152.45 g. proof lead and gave a button weighing 3.475 g.; 0.975 g. litharge was collected giving a bead of 0.08 mg. In a second test, the figures were bullion 20.62 g., lead 142.45 g., button 3.422 g., litharge 1.322 g., bead 0.28 mg. Probably the high litharge and bead were due to the early formation of an unabsorbed scum on the cupel, upon which later feathers formed, particles of which adhered to the litharge recovered. The third sample yielded the highest recovery of litharge of any test made, 1.50 g., due perhaps to the same causes. The figures were, bullion 20.79 g., lead 139.06 g., button 3.25 g., litharge 1.50 g., bead 0.30 mg. Extreme tests were made on three grades of silver—proof, 900 silver 100 copper, 750 silver 250 copper. Starting with 2 and 3 per cent actual silver on the 140-g. lead buttons, the results were:

	2 Per Cent Silver Litharge		3 Per Cent Silver Litharge	
	Weight, g.	Silver, Mg.	Weight, g.	Silver, mg.
Proof	1.04	0.24	1.28	0.26
900	1.16	0.20	0.97	0.26
750	1.24	0.21	0.71	0.21

Legal Notes

By Wellington Gustin

Cherokee Fertilizer Company Wins Judgment

From Georgia comes a case wherein the Cherokee Fertilizer Co. brought an action on a note against one J. A. Smith, recovering a judgment thereon in the lower court which was affirmed on appeal (100 S. E., 719). Justice Luke delivered the court's opinion.

It appears from the evidence that the fertilizer company had a suit pending against Smith for several thousand dollars, and a settlement of that case was had between the parties, and the case marked settled upon Smith paying certain money and delivering certain stock to the company. The payment was made and received in full settlement of that claim, and a receipt given and marked in full payment of all claims to date.

Subsequently the present suit was instituted upon a note signed by Smith and another which was not mentioned by either of the parties at the time of the settlement. In fact, the attorneys representing both testified that neither of them knew about the note. The defendant Smith pleaded that there was a full settlement because of the receipt in the settlement above indicated.

The court said that if one who had several different demands against another accept payment of one or more and gives a receipt therefor, there being at the time no mention of the other demands, a mere recital in the receipt that it is full payment of all claims to date is without consideration so far as relates to an unsettled note signed by the party making the payment, and another which was not mentioned or in the minds of the parties at the time of such settlement and the signing of the receipt, does not estop the holder of the unsettled demand from asserting that demand, nor does the signing of the receipt render it incumbent upon the holder of that demand to refund the money received upon the settlement as to the disputed claims.

Detroit Chemical Works Wins Case

The Supreme Court of Michigan has affirmed the judgment in favor of the Detroit Chemical Works of Detroit, in the action brought against it by the Dow Chemical Co. of Midland, Mich. The parties had entered into a written contract whereby the latter agreed to purchase 900 net tons of sulphuric acid, commercial grade, of approximately 60 deg. Bé. strength, from the former company according to certain terms and conditions as stipulated. This contract was executed on June 8, 1915; the price was $12 per ton, f.o.b. vendor's tank cars, Detroit, Mich., less freight to Midland; the deliveries were to be made at the rate of about seventy-five tons per month beginning Jan. 1, 1916; the terms of payment were net cash in ten days.

The conditions in the contract pertinent to this case were: "Each shipment to be treated, for the purpose of settlement, as a separate and independent sale, but if buyer fails to make payment for any materials furnished by vendor according to terms of sale, said vendor may defer additional shipments until payment is made, or may cancel this contract at his option. . . . The vendor reserves the right to decline to make deliveries on this contract except for cash whenever said vendor shall have any doubt as to buyer's responsibility and so informs buyer. Deliveries to be renewed according to contract terms when buyer shall have satisfied vendor as to his responsibility."

Facts Out of Which the Suit Arose

On Jan. 20, 1916, the Dow Chemical Co. wrote to the Detroit Chemical Works: "There is due on our contract seventy-five tons of 60 deg. acid this month. This is approximately two cars. Please make shipments about three or four days apart." On Jan. 22 the defendant replied: "We are shipping you one car today, in compliance with your request, and a second car will follow the latter part of next week, which we trust will be satisfactory." The first car was shipped and invoiced as of that day, the invoice reaching plaintiff on Jan. 27, the car arriving in Midland on Jan. 29, and was not delivered at plaintiff's plant until Jan. 31.

On Feb. 3 plaintiff wrote: "Please rush shipment of the balance of sulphuric acid due on our contract for shipment during January. Also get the February quota out for us. These cars may be distributed approximately in even shipments over this month." On this same day and before receiving this letter, defendant had shipped the second car. It was billed out as of Feb. 3, but did not reach Midland until Feb. 8. It was not received by plaintiff until Feb. 19. This was considered by both parties as in fulfillment of the January quota.

On Feb. 7 defendant wrote plaintiff a letter, declaring its election to cancel the contract between the parties. It sets out that payment for the first shipment of Jan. 22 matured Feb. 1, and no remittance had been received to cover. This reached plaintiff on Feb. 10 and on the same day its agent went to Detroit and paid defendant for the first car shipped, and on Feb. 12 plaintiff paid for the second shipment of Feb. 3.

Contentions of Defendant and Plaintiff

Defendant refused to make further shipments as requested by plaintiff, claiming it had cancelled the contract by its letter, and that it had the right to do so. Plaintiff was compelled to buy acid in the open market, and brought this suit to recover the damage it sustained by reason of the failure of defendant to furnish the acid according to the contract.

It was the contention of plaintiff that it was not required to pay for the acid, according to the terms of the contract, until ten days after its delivery to it at Midland and a reasonable time allowed for the inspection thereof. Also it contended that by making the shipment on Feb. 3 defendant waived the default of plaintiff in not having paid for the car shipped within ten days after Jan. 2, and that thereby it became estopped from canceling the contract as it attempted on Feb. 7.

Court Construes Contract of Sale "Net Cash in Ten Days"

Over plaintiff's objection defendant offered proof of a general custom of trade by which the language of the contract, "Terms of payments: Net cash in ten days," was construed to mean payable in cash within ten days after date of invoice or shipment. After the evidence was all in, the court directed a verdict for the defendant, holding that it was justified in terminating the contract for the reasons stated, and that there was no waiver of its terms which prevented it from relying on such cancellation as a defense in this suit.

On the appeal the two major questions presented to the Supreme Court were: When was the payment due

of the invoice of Jan. 22? And if the right to cancel the contract accrued to the Detroit Chemical Works by reason of the delay in the payment of the invoice, did this company by its conduct waive that right?

JUDGMENT FOR DEFENDANT AFFIRMED

The Supreme Court said that in view of the uniform sales act as adopted under contract of sale of sulphuric acid of a certain grade, deliverable in installments f.o.b. vendor's tank cars at vendor's city, less freight to buyer's city, terms net cash in ten days, the ten days' time began to run on delivery on board vendor's tank cars at its city and consignment of the car to the buyer; for the contract provision as to deduction of freight to buyer's city did not amount to naming such city as the point of delivery, and the right to inspect, implied from the specification of a particular grade of acid, did not postpone delivery and passage of title until inspection and acceptance, as title to goods may pass even though the right to acceptance be reserved.

Again, under the uniform sales act, where the installment sale contract expressly gave the seller the option to cancel for default in any payment, such right to cancel was not affected by a provision that each shipment was to be treated, for the purpose of settlement, as a separate and independent sale.

On the question of waiver the court said that where payment on an installment sale contract was due Feb. 1, shipment by seller of another installment on Feb. 3, not knowing whether payment due Feb. 1 was in the mail, would be held not a waiver of failure to pay Feb. 1, for "waiver" implies the intentional abandonment of a right by a person entitled to exercise it, who has at the time full knowledge of the existence of the fact on which the right depends, and the facts relied on must also show that such intent was communicated to and understood by the party claiming the waiver; it being, in effect, the abandonment of a particular obligation and an agreement to substitute another in its stead.

Neither was the seller prevented, because of its own default, from taking advantage of its right to cancel installment contract of sale for failure of buyer to make payment due Feb. 1, where although seller had not made the last January shipment during that month, it made such shipment Feb. 3; it not knowing until about the date of its cancellation, which was after Feb. 3, that the Feb. 1 payment was not mailed by buyer on Feb. 1, so that the seller was not in default when it exercised the right of cancellation or knew of facts justifying cancellation. Judgment for defendant was therefore affirmed.

A Controversy in Pig Iron Sales

A judgment for E. C. Humphreys Co. and against Rathbone Mfg. Co. has been affirmed by the Supreme Court of Michigan. The former is located in Detroit and sells pig iron on a commission basis, while the latter manufactures soft gray iron castings at Grand Rapids. On Nov. 19, 1917, plaintiff sold defendant a car of No. 1 iron to be paid for not later than Jan. 20, 1918. It was delivered to defendant, in Grand Rapids, who refused to accept because it did not grade up to No. 1 iron. Subsequently by agreement the price was reduced 50c. a ton, and defendant accepted it, but never made payment for same. About Jan. 5, 1918, or later, defendant purchased from plaintiff, by telephone, a car of "high-silicon iron," which was delivered. Defendant took exception to the quality of this car and it was resold to other parties by plaintiff. On Nov. 19, at time the first-mentioned car was contracted for, the parties entered into a written contract by which paintiff sold to defendant 850 tons of iron of various grades, to be delivered monthly over the first half of the year 1918. No iron was ever delivered under this contract.

These contracts were separate and independent of each other. The plaintiff being unable to get its pay for the first car delivered, it began this suit on April 17, 1918, to recover therefor and also to recover damages for defendant's failure to accept and pay for the car of "high-silicon iron." Defendant set off as damages plaintiff's failure to deliver iron under 850-ton contract. On trial the jury returned a verdict for plaintiff, $1,672.70, which was due on the car delivered and accepted, but refused to award defendant any damages on its matters of set-off. Defendant appealed its case.

Now, on the trial defendant conceded it owed plaintiff $1,672.70 for the car it accepted. The trial court held that plaintiff could not recover damages by defendant's refusal to accept the car of "high-silicon iron," because this was an oral contract, the order given by telephone, and involved more than $100 and was void under the statute of frauds. The only question to be decided by the Supreme Court was that relating to plaintiff's refusal to deliver iron under the 850-ton contract.

TIME OF DELIVERIES CONTINUED

This contract provided with reference to time of shipment: "Shipments: In about equal monthly quantities over the first half of 1918, buyer to give seller the quantity of each grade to be shipped on or before Dec. 1, 1917."

Very soon after making this contract, on Nov. 19, 1917, defendant ordered several cars of iron on the contract, notwithstanding it did not obligate the plaintiff to begin shipments until January. But defendant urged plaintiff to fill the order. Plaintiff advised that the terms of the contract would have to be changed from thirty days' time to ten-day drafts, subject to a discount of one-half of one per cent, applying to the whole contract. Defendant did not consent to this change until Jan. 4, 1918, and ordered three cars of No. 1 and No. 2 iron. It charged that plaintiff promised shipments would begin immediately if consent was given to the change in the terms, thereby waiving the time fixed in the contract for the shipments to begin. However, the order for three cars was subsequently countermanded or merged in an order for three cars on Jan. 25. The Supreme Court held plaintiff's failure to ship this last order placed it in default as to that, but it could not be liable on any of the previous transactions. And the jury failed to find any damages for this default.

Under the provision of the contract as to shipment, quoted above, the court held that plaintiff was under no obligation to begin shipments before Jan. 1, 1918, and that if it made shipment upon the last day of the month it was a compliance with the contract.

French Duties on Chemicals

The *Journal Officiel* of March 2, 1920, publishes a new status of chapters ex-XVIII (chemical products), ex-XIX (prepared dyes) and ex-XX (colors) with their coefficients of increase in specific rates of duties established in accordance with the new nomenclature specified by the law of Nov. 7, 1919, these new chapters being substituted for the corresponding ones in the table of coefficient increases as specified in the decree of July 8, 1919.—*The Review*, March 15, 1920.

Ozone in the Chemical Industries

By Chester H. Jones

WHILE a large amount of data has been published covering a number of installations where ozone is employed in air and water sterilization and purification, and while there has been considerable promotion propaganda using results of laboratory experiments with ozone in chemical applications, there has on the whole been little information available on commercial uses of ozone involving purely chemical reactions. It is known that a number of companies have purchased ozonators of the commercial type and are running them continuously in chemical plants, but definite information concerning their performance has been consistently withheld from publication.

Apparatus

There is now on the market a standard apparatus which is reliable as to both continuous operation and uniform output of ozonized air. Fig. 1 illustrates the three-tube laboratory unit and Fig. 2 a two-unit bank of six tubes per unit. The table herewith will show guaranteed output of this apparatus as listed from the three-tube laboratory type up to the ten-unit type consisting of six tubes per unit.

AIR FLOW AND OUTPUT OF SPRAGUE LABORATORY AND INDUSTRIAL OZONATORS

Number of Units		60 Cycles				133 Cycles			
		Grams O_3	Watts	Air per Hr. Cu.M.	Cu.Ft.	Grams O_3	Watts	Air per Hr. Cu.M.	Cu.Ft.
1	3-tube	2½	75	1	35				
1	6-tube	6½	200	2½	90	13½	400	5	180
2	6-tube	13	400	5	180	27	800	10	360
3	6-tube	19½	600	7½	270	40½	1200	15	540
4	6-tube	26	800	10	360	54	1600	20	720
5	6-tube	32½	1000	12½	450	67½	2000	25	900
6	6-tube	39	1200	15	540	81	2400	30	1080
7	6-tube	45½	1400	17½	630	92½	2800	35	1260
8	6-tube	52	1600	20	720	108	3200	40	1440
9	6-tube	58½	1800	22½	810	121½	3600	45	1620
10	6-tube	65	2000	25	900	135	4000	50	1800

Maximum concentration:
3-tube, 2.5 g. per cu.m.
6-tube, 2.6 g. on 60 cycles, 2.7 g. on 133 cycles.

The general type of tube that is employed in the construction of these ozonators is illustrated in Fig. 3. Alternating electric current for the operation of this machine is first led to a transformer, where it is stepped up to a voltage of about 10,000 to 12,000. One of the transformer leads is then brought to the busbar of the machine and the other to the frame, so that a complete circuit may be traced from the transformers through the inner cylinder, across the air gap, and through the glass tube which forms the dielectric to the copper plating on the outside of the glass tube, which is in turn grounded to the frame and then back through return leads.

As the high-voltage current passes through the air gap, it does so in the form of a brush discharge which forms a purple ring completely filling the annular opening. This is not a spark, but a true so-called "silent discharge," although as a matter of fact it is accompanied by a rushing sound.

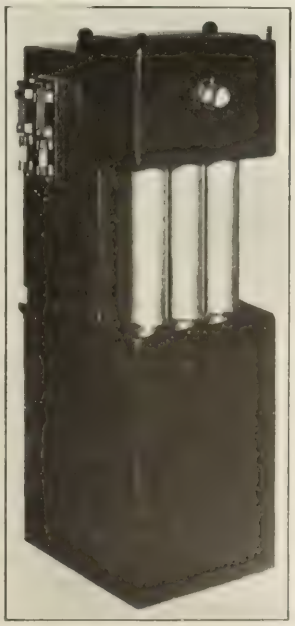

FIG. 1. STUBE OZONATOR

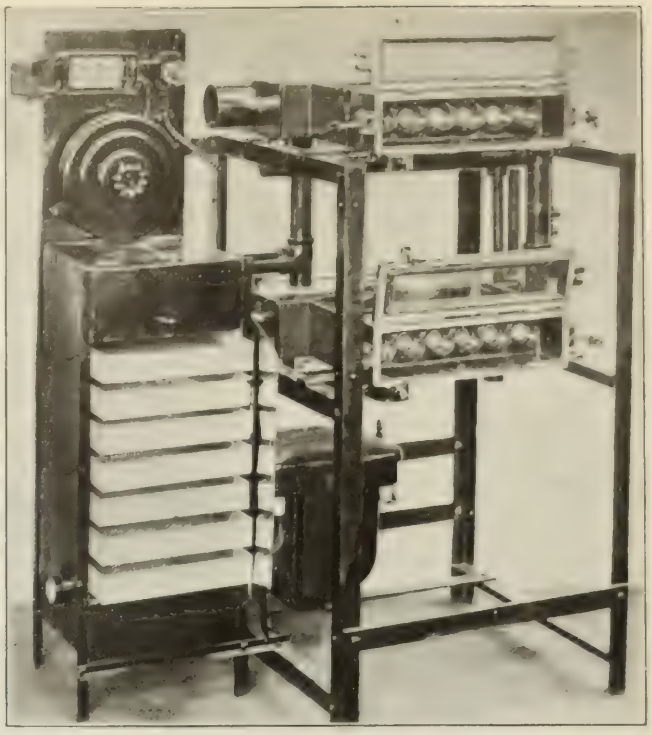

FIG. 2. A TWO-UNIT BANK OZONATOR, FOR OPERATION ON 110- AND 220-V., 60-CYCLE A.C.-OPEN

The copper tube which is shown surrounding the glass tube is employed for the protection of the glass, and while entirely non-essential as far as the operation of the machine is concerned, it is of great practical importance, preventing the frequent breakages and shutdowns which would occur in case the glass surface were left exposed.

The water shown surrounding the tubes is employed for the purpose of keeping down the temperature, which becomes quite high when the machine is in operation. As will be seen in this type of ozonator, the generating tubes are mounted in a casing so formed as to provide a chamber at each end of the open tube. Air is admitted under light pressure or subject to suction into the chambers at one end of the tube, and passes through the brush discharge and the annular space between the inner and outer electrodes. Passing through this discharge a portion of the oxygen in the air becomes ozonized and this ozonated air is conducted through piping to the point of application.

Referring to Fig. 2, trays with a wire gauze bottom shown are filled with a layer of calcium chloride. All the air going into the generating tubes is passed through the calcium chloride, thus giving a dry air and insuring successful operation of the ozonators.

The actual amount of ozone that can be generated in a tube of this kind is nearly proportional to two factors, namely, the voltage and the frequency of the electric current forming the discharge. Actual determination of these factors has been arrived at by observation rather than by any theoretical basis. The most practical limit of voltage has been found to be from 10,000 to 12,000 volts, the limitation being caused by the difficulty of securing adequate insulation when this limit is exceeded. With this voltage as a maximum,

most of the small outfits are operated at a frequency of sixty cycles, which is now standard central station supply. On medium-sized plants 133 cycles is often used, thus securing the double output from each tube. Up to now the highest frequency found in practical use in the largest installations is 500 cycles, which is employed in European countries and to some extent here.

Wax Bleaching

The Theodore Leonard Wax Co., of Haledon, N. J., has installed a twelve-tube unit industrial ozonator with a capacity of 12.5 g. per hr., and operates it continuously for the bleaching of wax, as shown in outline in Fig. 5. It will be noted that the air is forced through the ozonators and the ozonized product bubbles through about a 25-lb. (11.3-kg.) charge of wax contained in the tub. This charge of wax is kept molten by steam pipe introduced in a single turn through the tub. When ozone is passed at the rate of 12½ g. per hr., a charge of wax is bleached in a period of 4 to 5 hr.

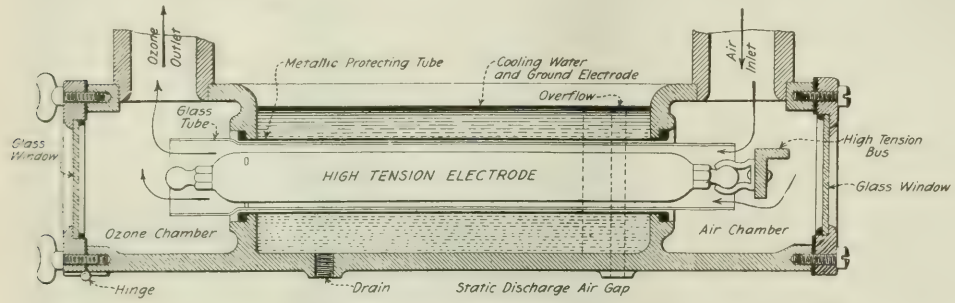

FIG. 3. SECTIONAL VIEW INDUSTRIAL OZONATOR TUBE

Bleaching Textiles, Fabrics, Etc.

While considerable industrial work has been done along these lines, it has been surrounded with so much secrecy that definite data on installations are not available. Some knowledge of the research work done, however, should be of value.

In the bleaching of textile fibers and textures, a series of operations, the object of which is not only to decolorize the fibers but also to bleach them of any foreign substances, is performed. The bleaching or decolorization comprises the destruction of the natural colorizing matters or of the accidental colorizing matters which may be attached to the fibers through direct or indirect oxidation phenomena. To obtain this decolorization the oxygen of the air, chlorine in its different states, chlorate, bichromate, permanganate or ferricyanide of potassium and barium peroxide are used. For instance, the product called "ozonine," commonly employed in bleaching, is possibly composed of about 125 parts of resin, 200 parts of turpentine oil, 25 parts of hydrate of potassium which is dissolved in 40 parts of water, and 90 parts of ozonized water. Ozonized water in turn could be replaced by peroxide, such as peroxide of sodium.

At first the bleaching of textile fibers was obtained by exposure to the air. In this action oxygen, or better, ozone, oxidizes the colorizing matters and makes them soluble in a dilute alkaline solution. This bleaching, obtained by air or even by ozonized air, requires the action of solar light, according to A. and P. Buisine. If textile fibers are subjected to the action of ozone alone for a certain length of time, that is, until the bleaching obtained is satisfactory, the fibers become fragile and their resistance to wear is lessened to a large degree.

If, on the contrary, instead of ozone artificially obtained, chloride of lime alone is used, the bleaching obtained is insufficient, but the strength of the fibers is less affected than by ozone.

Bleaching by ozone alone takes place at a regular rate, but at a certain period the decolorizing action decreases and at the same time destruction of fiber becomes imminent. The moment at which bleaching is sufficient is consequently to be carefully watched and the action of ozone is then to be promptly stopped. If at this period the fibers are immediately put into a weak solution of chloride of lime, bleaching begins again. This action increases with a greater intensity than that by the use of chloride of lime alone.

Perfect bleaching of textile fibers can therefore be rapidly produced by using short ozonizations, followed by weak solutions of chloride of lime, without having to make use of slow bleaching by exposing on a flat surface. After this treatment the fibers are found to have kept their primitive strength.

From observations made by M. Frohlich, the Siemens and Halske Societies and the Freiffenberger Bleich-u.-Appretur Anstalt, it has been possible to bleach textile fibers satisfactorily by the combined action of ozone and of chloride of lime. Usually gray threads or yarns, after they have been prepared according to the usual methods by boiling in a washing bath of soda, are simply immersed in a concentrated solution of chloride of lime, removed and exposed to ozone and again placed for a few hours in a weak solution of chloride of lime. On being removed from the latter the fibers are rinsed, partly dried and placed again in the ozone room in a damp state. By this process the strength of the agents of bleaching is gradually diminished. The operations are performed in succession and repeated until the required degree of bleaching is obtained.

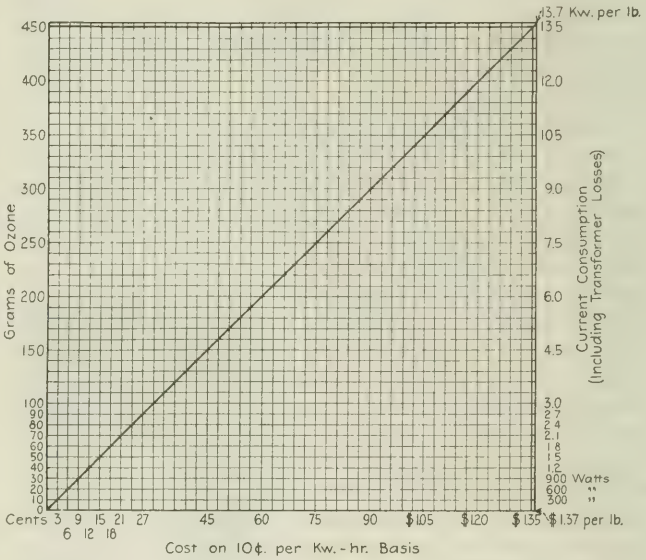

FIG. 4. CHART SHOWING COST OF MAKING OZONE

The ozone room must be constructed in such a way as to have all the parts of the yarns or threads submitted in turn and uniformly to light. Light of arc lamps can be used for this purpose. Currents of ozone must also act successively and uniformly on all the parts of the fibers. To obtain this result ozone must come into the room through as many apertures as possible, disposed in a uniform manner, which is effected by the use of perforated pipe protected by shellac or paraffine. In addition to this the textile fibers must be kept in motion so as to have their various parts placed under the action of ozone. This result can be obtained by means of a drum-shaped apparatus which is made to rotate and on which the fibers are placed.

If, after having prepared fibers according to the usual method, textiles are immersed in certain weak solutions of ammonia, of turpentine and ammonia emulsion, of turpentine essences, of soap or resin and ammonia, or of commercial indigo, and subsequently placed under the action of ozone, white fumes of aid to the bleaching process are formed. These fumes, the result of the oxidation of the substances with which the fibers are impregnated, in addition to compounds formed on

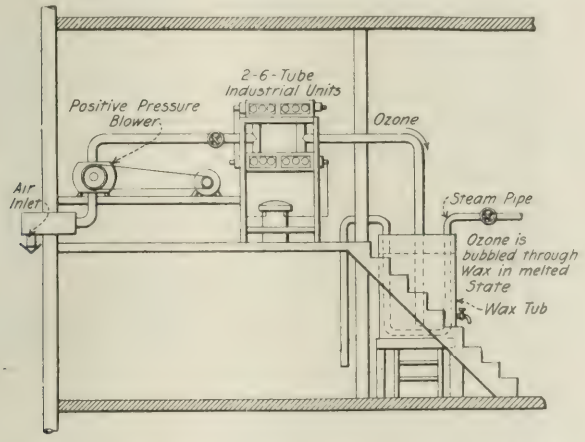

FIG. 5. OZONATOR FOR BLEACHING BEESWAX

the texture itself, facilitate the oxidation when placed in a slightly acidified bleaching bath.

Usually the textile substances under process after having been prepared in the usual way are immersed in solutions made of the chemical products enumerated above. After this operation they are taken out and partly dried, when they are placed in the ozone room for a certain length of time, then immersed in weak solutions of chloride of lime, partly dried and again placed in the ozone room. During these operations the effects of the bleaching are watched and the operations stopped at the proper point. Usually two rooms are used for the treatment and ozone is alternately introduced at intervals of a half hour. This saves loss of time and permits ozone to act gradually.

Bleaching by ozone is more or less rapid according to the nature and the condition of the fiber to be treated. It is economical of time and results in superior bleaching than that obtained by the old process of spreading textiles in the sunlight. The consumption of ozone is also variable according to the nature, the condition, the time of exposure, and also the volume of textiles to be treated, as well as according to the chemical substances which are used in conjunction.

Flax, hemp, jute, cotton, paper pastes, etc., can be bleached in a similar manner.

Flax texture is first placed in a mixture containing 15 g. of caustic soda at 36 deg. Bé. and 15 g. of ozonized oil per liter. After this has been boiled for 12 hr. the texture is washed and passed into neutralizing acid, and finally rinsed with clear water. A bleaching bath (peroxide of sodium) is then prepared. It is composed of the following formula:

Water, liters	1 000
Ozonized oil, kg	5
Peroxide of sodium, kg	7 5
Sulphuric acid, 60 deg., kg	10

This bath is made alkaline, and after the flax has been immersed it is heated to 80 or 90 deg. C. The bath is properly agitated during this treatment and at the end of 4 hr. the textures are taken out, washed, passed into acid and finally rinsed. The operation is continued until the desired bleaching result is obtained.

Bleaching Paper Pulp

Ozone is said to produce excellent results on paper pastes. The bleaching is not only perfect, but rapid and economical. It is said that the use of anti-chlorine such as hyposulphite of soda and nitrate of soda as used in the present processes may be avoided. Usually a current of ozone is sent through the bath of chloride of lime in which the paper paste is being bleached. This increases the action of the chloride and reduces the quantity used.

Sponge Bleaching

In the bleaching of sponges the raw sponge is first soaked in a solution of sulphuric acid to loosen the dirt and organic coloring matter. After wringing out the water, the damp sponge is placed in a strong ozone atmosphere, approximately 3 to 4 g. per cu.m. for a period of 3 to 7 hr., the time required depending upon the kind of sponge and not the size.

After a pale light-colored bleach is obtained, the sponge is rinsed in a solution of sodium carbonate to remove the free oxidized coloring matter and to neutralize the nitric acid formed during the treatment. This alkaline bath darkens the sponge somewhat to a canary yellow and its action is checked and tempered by again rinsing in a weak sulphuric acid solution followed by a thorough washing in plain water to remove all the chemicals and to secure a neutral condition.

A commercial plant along these lines was put in operation during the war when the price of the more usual reagent, potassium permanganate, was high, a two-unit 500-cycle plant being employed. This was discontinued, however, simultaneously with the drop in the permanganate market.

Drying Varnishes and Paints

The so-called drying of paint oil, such as linseed, is not caused by evaporation, but by oxidation, and when driers are mixed with paints or oils they are used simply to hasten this oxidation. By producing a partial oxidation of the oil before it is applied the drying is greatly hastened and more thoroughly accomplished and the process may even be continued after application by drying in the presence of ozonized air.

On examining a coating of oil paint on any surface it is found that the surface hardens over in a thin skin which shuts out the air from the lower layers and often requires a long time for the hardening to become deep seated and completed. If, on the other hand, the paint is treated with ozone previous to application, the ozone will apparently cause the oxidation to occur throughout

the entire thickness of the layer and a more thorough drying is thus secured.

An application of these ideas is shown in Fig. 6, giving a layout at the Heinze Electric Co., Lowell, Mass., where ozone is introduced into the drying ovens containing automobile magnetos. The armatures, after being wound, are subjected to impregnation with oil under vacuum. The oil thoroughly penetrates the windings, but when dried it hardens on the surface, leaving the interior in a soft condition. When magnetos are

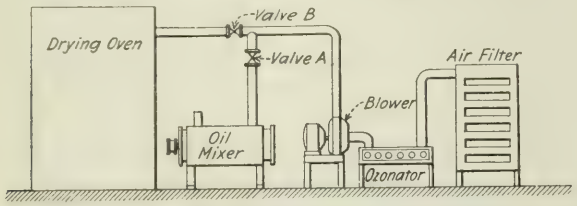

FIG. 6. PAINT DRYING APPARATUS

operated the armature is run at high speed and the centrifugal force is often sufficient to throw off this soft oil, thus spoiling the impregnation of the winding. This is remedied by ozonizing the oil before using.

The oil is first placed in a mixer where it is stirred up by a dasher, while the stream of ozonized air passes through the mixer and is brought into intimate contact with the oil by which the ozone is absorbed. After a few hours the oil is so charged with ozone that it may then be applied to the armatures with the certainty of its hardening thoroughly throughout. The armatures are then dried in the ovens, shown at the left of the sketch, which are also charged with ozone to hasten and improve the surface drying. Several musical instrument manufacturers have installed ozonator systems for furnishing ozonized air to drying rooms; Fig. 7 shows the layout at the Schubert Piano Co.

Since ozone oxidizes with enormously greater speed than oxygen, its value in paint and varnish drying is evident. In the painting of automobile bodies hurried drying is demanded by the crowded condition of the factories. Recent tests with ozonized air showed after 2 hr. an increase in weight of the painted body of 3.34 per cent, while with ordinary air the corresponding increase was only 1.51 per cent. This increase was due to the absorbed oxygen and fairly measures the relative rapidity of the two drying methods.

Oil Oxidation

Little data are available on the subject of oil oxidation. It is known that the Standard Oil Co. is making experimental tests with laboratory equipment, while some of the vegetable and animal oil producers are proceeding in like manner. There is every reason to believe that this will eventually be one of the largest fields for the employment of ozone. Oil may be completely solidified by treatment extending over a period of about three weeks, and the gummed oil, after it has been ground, is used in the manufacture of linoleum. Cottonseed oil may also be decolorized by the use of ozone.

For treatment of linseed and similar oils for bleaching, bodying and solidifying, the practice at present is to allow ozone, $\frac{1}{8}$ g. per liter per hr.; air, $\frac{1}{8}$ cu.m. per liter per hr. The oil should be treated in a mixer in which it is continually agitated by revolving paddles. Simply bubbling the ozone through the oil is not satisfactory and requires a much longer time for similar results.

Rapidity of thickening depends upon the temperature in which the oil is treated. Raw oil when run at 65 to 90 deg. C. thickens rapidly, solidification being secured in 6 to 8 hr., but the oil becomes darkened. When run at temperatures below 40 deg. C., the thickening proceeds more slowly (8 to 10 hr. for solidification), but the oil is bleached.

For bodying paint or varnish a run of 6 hr. is usually sufficient. For linoleum the average run for solidification is 8 to 10 hr.

Cold Storage Application

Ozonators have a wide use in the deodorizing and purification of air for cold storage chambers. While the activities of the bacteria which cause decay and mold growth in food materials are very largely checked by keeping the surrounding air properly dried and near the freezing point, the addition of ozone to destroy the odor carried in the air has achieved remarkable results. It furnishes a means of purifying the air of the storage room without ventilation and consequent loss of refrigeration required to cool newly admitted air. Thus, it is claimed that eggs in cold storage will

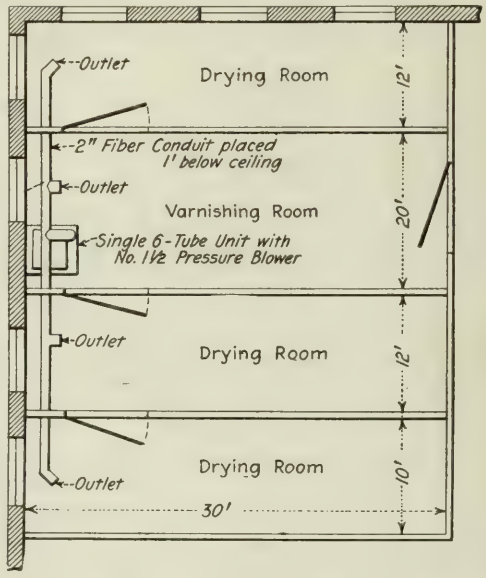

FIG. 7. OZONATOR FOR DRYING VARNISH ON PIANO CASES

carry much better in ozonized air. Not only is the average quality of eggs taken out much better, but if there are any cracked eggs in the cases, the cracks, instead of becoming moldy, will be dried up just as if they had been exposed to sunlight and air.

Future Developments

The future outlook for the use of ozone in the chemical application is promising. Ozonized air of high ozone content is available in such quantities as to permit commercial employment in the oxidation of the more rare organic chemical processes. Where larger quantities are required, a solution is suggested by the statement of Georges Claude that liquid oxygen at low temperatures is easily transformed by efflux into ozone.

Large plants exist in this country capable of producing oxygen at a few cents per thousand cubic feet. It requires no great imagination to see gaseous ozone produced from simple mechanical apparatus in the near future. Ozone thus cheaply prepared for the market opens up unlimited possibilities in chemical industries.

Report on Test of New Brunswick Oil Shales in the Wallace Retort

THE summary report of the Mines Branch of the Department of Mines of the Dominion of Canada for the year 1918 contains a report on the test of New Brunswick oil shales in the Wallace retort, together with a description of the Wallace retort, from which the following is abstracted:

Description of Retort

The new type of retort for the carbonization of coal and retorting of oil bearing shales is the invention of W. G. Wallace, superintendent of the St. Claire Gas Co., of East St. Louis, Mo. The essential idea of the retort is that of removing the volatile products without subjecting them to a temperature higher than that at which they are liberated from the shale. The design is illustrated in detail in Fig. 1. The distilling chamber *A* is cylindrical in cross-section and of less diameter at the upper than at the lower end, this chamber being surrounded by a circular combustion chamber *B*. A perforated take-off duct *C* is centrally located, the products of distillation being removed at the bottom through the pipe 2. The pipe 2 can be disconnected from the outlet of the take-off duct, permitting the bottom of the distilling chamber together with the perforated takeoff duct to be removed downwardly for the removal of the retorted shale. The perforated take-off duct is preferably of uniform circular cross-section, so that the annular space between it and the wall of the distilling chamber will diminish gradually in area from the lower to the upper end, thereby causing a uniform distribution of heat through the material within the annular space. This design of retort causes the products of distillation to pass through the cool material away from the heated wall of the retort, and thus materially aids in preventing the formation of unsaturated hydrocarbons which are produced at high temperatures and formed to a greater or less extent in usual types of retorts, where the products of distillation are brought into contact with the heated walls or the heated material within the retort from which the volatile products have already been removed.

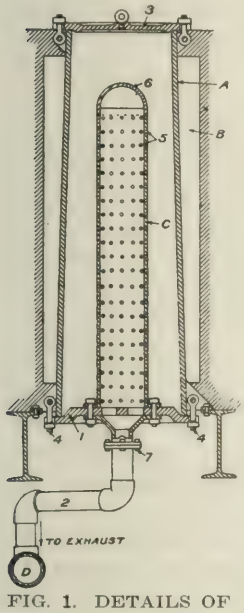

FIG. 1. DETAILS OF WALLACE RETORT

This design secures the advantages of low-temperature distillation in that the volatile products are given off at a minimum temperature, immediately cooled and removed from the influence of heat. It is further claimed that this method of distillation produces a larger yield of oils due to the fact that the vapors are not subject to excessive heating which causes the breaking up of the oils into permanent gases.

Tests on New Brunswick Oil Shale

The shale was taken from an opening on seam 1, Frederick Brook, Alberta mines, and represented a fair average of the seam, which was 4½ ft. in width. Two tests were conducted, the samples weighing 81 5/16 and 80 lb. each, the shale being crushed to ½-in. size.

Test No. 1. Before charging with the shale, the retort was brought to a cherry-red heat, while the temperature of the combustion chamber was 1,450 deg. F. (787 deg. C.). Pyrometers were placed in the combustion chamber, in the retort between the outside walls and take-off duct, and in the bottom of the eduction pipe, and the temperatures throughout this run were recorded at these points, at 15-min. intervals. The results are shown in Table I, together with the quantity of oil and gas recovered during these periods. The oil recovered contained a small quantity of water which was not determined.

TABLE I. RESULTS OF TEST NO. 1

Time	Temp Combustion Chamber, Deg. F	Temp Retort, Deg. F	Temp Reduction Pipe, Deg. F	Cu Ft Gas	Weight of Oil, Lb	Oz
9:20 a.m.	1,480		1,100			5
9:35 a.m.	1,480	240	600	30	2	11
9:50 a.m.	1,490	280	500	50	2	6
10:05 a.m.	1,510	510	540	20	2	7
10:20 a.m.	1,520	620	650	25	2	6
10:35 a.m.	1,540	720	700	25	2	3
10:50 a.m.	1,530	820	810	25	1	

Summary of Results

		Per Ton of Shale
Shale charged	81 lb., 5 oz	
Oil recovered	13 lb., 6 oz	43 U. S. gal.
Gas	175 cu ft	4,290 cu ft
Spent shale	52 lb., 15 oz	1,297 lb

TABLE II. RESULTS OF TEST NO. 2

Time	Temp. Combustion Chamber, Deg. F.	Temp. Off-Take Duct, Deg. F.	Quantity of Oil, Lb.	Oz
11:25 a.m.	1,360	740		
11:40 a.m.	1,400	330		14
11:58 a.m.	1,410	400	1	3
12:10 p.m.	1,420	510	1	8
12:25 p.m.	1,430	630	2	1
12:40 p.m.	1,440	710	2	6
12:55 p.m.	1,450	800	2	3
1:10 p.m.	1,460	900	1	8
			0	3

Summary of Results

		Per Ton of Shale
Shale charged	80 lb	
Oil recovered	11 lb., 14 oz.	39.6 U. S. gal.

Test No. 2. The temperatures of the combustion chamber and retort before charging were considerably lower than that which obtained for the first test, consequently the yield of oil at the end of the first 15-min. period was less. The temperature of the combustion

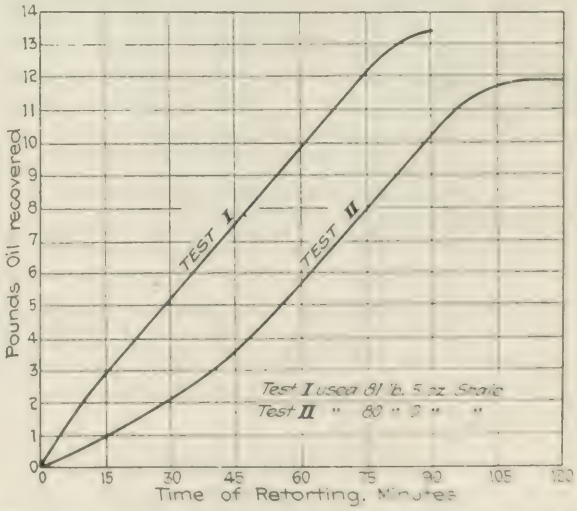

FIG. 2. CURVES SHOWING AMOUNTS OF OIL DISTILLED AT 15-MIN. INTERVALS

chamber and of the take-off duct were recorded and no record was made of the gas produced, since an air leak developed during the run. The results are given in Table II. The yield of oil of both tests are plotted against the time of distillation in Fig. 2.

Analysis and Results of Test of Sample of Oil Shale Sent to Fuel Testing Station

In order to check the results obtained with the Wallace retort, a general sample representing the entire quantity of shale retorted, and a sample of the spent shale were tested in the laboratories of the Fuel Testing Station. The results are given in Table III.

TABLE III. RESULTS OF CHECK TEST ON SAMPLE OF SPENT SHALE IN THE LABORATORIES OF THE FUEL TESTING STATION

Analysis:	As Received	Dried at 105 Deg. C.
Moisture	0.9	....
Ash	61.1	61.6
Volatile matter	33.9	34.2
Nitrogen	0.9	0.9
Distillations	No. 1 Without Steam 740 Deg. C.	No. 2 With Steam 550 Deg. C.
Yield of crude oil, per 2,000 lb. charged, U. S. gal	42	47
Yield of completely dried oil per 2,000 lb. charged, U. S. gal	37.6	37.3
Specific gravity, completely dried oil	0.87	0.89
Yield of gas per 2,000 lb. charged, cu. ft	3,700	3,540
Composition of gas :		
Carbon dioxide	25.1	31.0
Illuminants	2.5	2.6
Oxygen	0.2	0.5
Carbon monoxide	19.8	5.2
Methane	24.6	23.2
Hydrogen	21.7	32.6
Nitrogen	6.1	5.1
Calorific value, B.t.u. per cu.ft	380.0	351.0
Yield of ammonium sulphate per 2,000 lb. charged, lb.	16.0	19.0
Nitrogen in residue, per cent	0.5	0.7
Distribution of nitrogen from charge:		
In ammonia, per cent	21.0	24.0
In residue, per cent	42.0	58.0
In gas and unaccounted for, per cent	37.0	18.0
SAMPLE OF SPENT SHALE FROM WALLACE RETORT		
Nitrogen, per cent	0.5	....

The results obtained with the Wallace retort check remarkably well with that obtained with the retort employed in the laboratories of the Fuel Testing Station, especially since the maximum quality of oil is extracted by the laboratory retort.

Enamel Investigations at the Bureau of Standards

THE jumping off of small particles of enamel which results in the defect known in shop practice as "fish scaling" is probably the most serious defect to which enamels for sheet steel are subjected. It occurs intermittently in practically all the plants manufacturing this class of material in this country and entails losses running into millions of dollars to the manufacturers. At the request of the Metalware Manufacturers Association of America, the Enameled Metal Division of the American Ceramic Society and a large number of individual manufacturers, the Bureau is carrying on a comprehensive research in an endeavor to discover the cause or causes of this defect and the methods of controlling and eliminating it. This investigation was begun in July, 1919, and has been conducted energetically ever since.

Causes of Fish Scaling

Up to the present time, the Bureau has made ninety melts of enamel composed of twenty-one different compositions. These have been subjected to various treatments in firing and melting and have been applied in various ways to several kinds of steel. In all, over 4,000 sample enameled plates have been made up to date. This work has demonstrated that one of the most important factors in the production of fish scaling is too severe heat treatment in the firing of the enamel. Excess heat treatment may consist of firing the enamel at too high a temperature or of holding the enamel in the furnace for too long a time at a given temperature. Other important factors are the composition of the enamel, the physical and chemical characteristics of the underlying metal, the method of melting the chemical mixtures used in making the enamels and the shape and weight of the metal pieces that are enameled. These various factors have been investigated to a certain extent in this work and will be studied more thoroughly as the investigation progresses.

The data obtained in this investigation up to the present time have enabled the Bureau to be of very material assistance to several manufacturers in eliminating this trouble. It seems very probable that the completion of the investigation as now planned will definitely eliminate fish scaling, and likewise settle the interesting question of what is the physical basis of the phenomenon.

Acid-Resisting Enamels

For several months the Bureau has had in progress an investigation of the relation of composition of enamel to solubility in strong mineral acids. The need for this investigation was clearly demonstrated during the war by the difficulty manufacturers of acid-resisting enameled wares experienced in meeting the requirements of chemical manufacturing plants. The manufacturers of enameled kitchen wares are also interested in this problem.

Up to the present time thirty-three enamel compositions have been melted and tested. While the problem is a large one and the investigational work will necessarily be continued for some time, results so far obtained indicate that some of the commonly accepted conceptions of the relation between composition and acid resistance of enamels are erroneous. The chief of these misconceptions seems to be that oxides which are similar in nature chemically will have similar effects when incorporated in enamel compositions. That this is not always true is shown by the fact that calcium oxide tends to produce enamels with very low resistance to attack of acids while barium oxide produces quite resistant enamels.

Expected Results From the Investigations

In connection with the gathering of data on the chief object of this investigation, information is being secured in regard to relations of composition to their fusibility and to the tendency to chip or to craze, or crack. It is expected that as a result of this investigation the Bureau will be able to advise manufacturers of acid-resisting wares as to the methods of compositions to be used in producing wares of this class superior to any now being made, and also that it will enable the Bureau to be of material assistance to manufacturers of enameled ware for culinary purposes. As a matter of interest, it may be stated that as a part of this investigation an enamel has been produced which appears to duplicate in composition and working properties the best grade of French acid-resisting enamel.

Synopsis of Recent Chemical & Metallurgical Literature

Manufacture of Methylethylketone From Normal Butyl Alcohol.—Early in 1917, British Acetones, Ltd., began to produce acetone and normal butyl alcohol in large quantities by the fermentation of carbohydrate material in the presence of certain micro-organisms. There was at that time an almost unlimited demand for acetone, but the disposal of the rapidly accumulating stocks of normal butyl alcohol was a different proposition. No commercial demand had been developed and an attempt to substitute it for ethyl alcohol as a solvent in the manufacture of smokeless powder had failed. How this problem was solved is told by T. C. NEWMAN in the *Canadian Chemical Journal*, February, 1920, p. 47.

Under the direction of D. A. Legge, a process was developed for the conversion of the alcohol into methylethylketone (methylacetone) or M.E.K., as it was called in the plant. This product was accepted by the British Government as a cordite solvent and was used under the name of "cordite ketone."

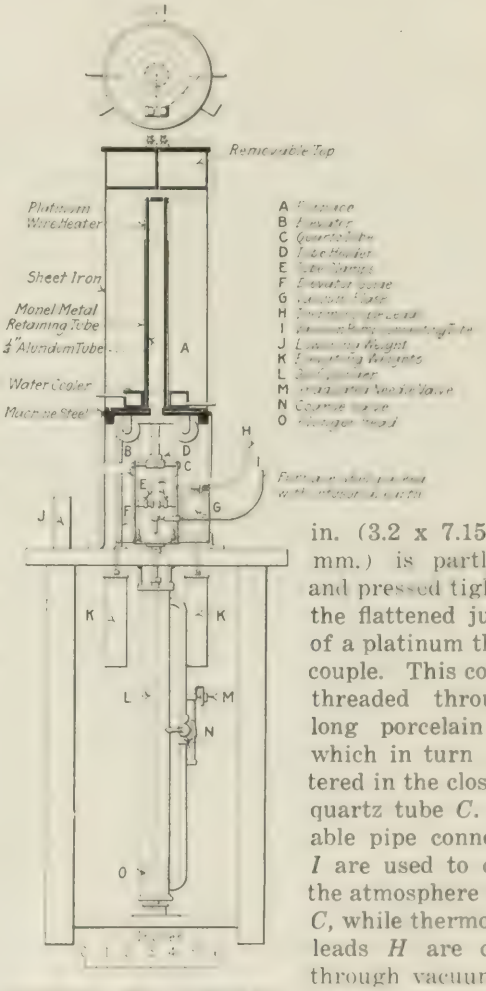
The theory of the process will be found in organic text books. The normal butyl alcohol is dehydrated, forming butylene, which treated with hydriodic acid yields β-iodo-normal-butane. This is converted into secondary butyl alcohol by heating with wet silver oxide. The secondary alcohol is then dehydrogenated, yielding methylethylketone. Of course, this is suited to the laboratory, but for a plant handling 25,000 lb. per day, substitutes for hydrogen iodide and silver oxide had to be found. In practice, sulphuric acid and water were used.

Butylene was prepared by passing the vapors of the normal butyl alcohol over heated kaolin. The temperatures required were markedly lower than those used in the preparation of ethylene from ethyl alcohol. The catalyzers were made up in batteries of three small units, each unit being held 40 deg. C. higher in temperature than the previous unit. The hot vapors from the catalyzers were passed through a gas cooler and gas separator. The butylene was then liquefied by an ordinary ammonia compressor and stored in high pressure storage tanks. The liquid butylene was pumped to a sulphating kettle, where it was treated with 60 per cent sulphuric acid. This reaction is extremely exothermic and is the most difficult step in the process. During the experimental stages there was a tendency for dibutylether to form, but this was overcome by details of plant operation.

The butylene hydrogen sulphate was diluted and distilled, forming secondary butyl alcohol with simultaneous regeneration of the sulphuric acid. The latter was reconcentrated in two 30-ton units. The secondary butyl alcohol was redistilled to free it from water and then passed through a second series of catalyzers similar in design to the first, in which it was dehydrogenated. Certain metallic oxides served as the catalyst. After condensation and separation from the hydrogen, the crude methylethylketone was distilled, yielding on a single distillation a very pure product containing as its only impurity slight traces of the pinacone.

Since the war the problem has been solved in a different manner through the production of butyl acetate, which is rapidly replacing amyl acetate as a nitrocellulose solvent. There are several reasons for this: The butyl alcohol is extremely pure, 90 to 95 per cent of it distilling within 0.5 deg. C. of the true boiling point; the odor of butyl acetate is not nearly so oppressive as that of amyl acetate; its technical effect is just as good; it is much cheaper in price.

Modified Rosenhain Furnace.—H. SCOTT and J. R. FREEMAN of the Bureau of Standards describe a perfected furnace for thermal analysis in Bulletin 152 of the American Institute of Mining and Metallurgical Engineers, and in Scientific Paper No. 348, Bureau of Standards. A sketch of the furnace is annexed and is practically self-explanatory. A small sample, ⅛ x ⅝ x ⅛



SKETCH OF MODIFIED ROSENHAIN FURNACE FOR THERMAL ANALYSIS

in. (3.2 x 7.15 x 3.2 mm.) is partly slit, and pressed tightly on the flattened junction of a platinum thermocouple. This couple is threaded through a long porcelain tube, which in turn is centered in the closed-end quartz tube *C*. Suitable pipe connections *I* are used to control the atmosphere within *C*, while thermocouple leads *H* are carried through vacuum flask *G* to a dial potentiometer. Steady current (5 amp. at 30 volts) passes through seventeen turns of 0.52-mm. platinum wire, wound around the top end of the ¼-in. walled alundum tube, and maintains the temperature of the top end continuously at something over 1,000 deg. C. The sample is gradually elevated to this heated region by means of gravity, weights *K* furnishing the motive power, regulated by oil by passing through needle valve *M*. Inverse-rate heating and cooling curves taken in this manner on transformationless steel (containing 28 per cent nickel) results in an almost geometric vertical between 250 and 1,000 deg. C.

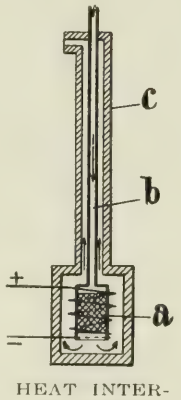
Recent Chemical & Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Benzoic Acid From Toluene.—A layer of toluene (100 lb.) is placed on the surface of about 250 lb. of 38 per cent HNO_3 in a suitable reaction vessel provided with a reflex condenser. After heating to about 90 deg. C., the reaction is started by adding 0.1 per cent paraformaldehyde. At the end of four or five days the reaction is complete and the upper layer of benzoic acid, benzaldehyde and toluene is removed and treated with alkali. The solution of sodium benzoate obtained may contain nitro compounds which may be removed by reduction to amino compounds. Benzoic acid is recovered by precipitation with an acid. It is claimed that the yield is nearly quantitative. The product is, of course, free from chloride. The process may also be applied to other oxidations of side-chains in aromatic compounds, such as the manufacture of orthonitrobenzoic acid from orthonitrotoluene. (1,332,028; VIRGIL COBLENTZ and HAROLD W. WALKER of New York, assignors to Commercial Research Co.; Feb. 24, 1920.)

Stopper.—WILLIAM M. GROSVENOR of New York has devised a stopper for use in connection with the distillation of inflammable volatile organic liquids. It is more permanent and efficient than the ordinary tinfoil-wrapped cork or rubber stopper. It consists of a short tube of block tin upon which a tapered rubber stopper is vulcanized. The rubber is protected with sheet tin about 0.015 in. thick, autogenously welded to the inner tube. (1,332,335; March 2, 1920.)

Heat Interchanger for Synthetic Ammonia Process.—The efficiency of the exchange of heat between incoming and outgoing gases in the Haber synthesis is increased by modifying the design of the interchanger in accordance with the principles set forth by Stanton and Pannel, *Philosophical Transactions*, A. 214, p 199; 1914. When the velocity of fluids exceeds a certain "critical velocity," turbulent motion (instead of stream line motion) is set up. The critical (mean linear) velocity is equal to a constant times the "kinematical viscosity" divided by the diameter of the tube. The "kinematical viscosity" is equal to the viscosity divided by the density. The constant is approximately equal to 2,500 for any fluid when dealing with smooth circular tubes and when using C. G. S. units. The "critical velocity" may be easily calculated provided that the density used corresponds to the pressure in the apparatus and that the value of the "kinematical viscosity" is taken for the temperature in question. In consequence of the turbulent motion of the fluid, the rate of transfer of heat across the separating partition between the two gases is very high, whereas with stream line motion of the fluid it is very low. The accompanying table gives data for an interchanger of the type illustrated, in which *a* is the electrically heated catalyst chamber, *b* the tube through which the incoming gases pass and *c* the tube for the outgoing gases.



HEAT INTERCHANGER

	Temp., Deg. C.	Pressure Atmospheres
Catalyst chamber	600	148
Inlet of *b*	20	150
Outlet of *b*	550	149
Inlet of *c*	600	148
Outlet of *c*	70	147

Diameter of tubes:
b—Internal, 2 in.; external, 2¼ in.
c—Internal, 3 in.
Volume of gas passing through the tubes 100,000 cu.ft. per hr., expressed as free hydrogen and nitrogen measured at 20 deg. C.

(1,329,397; HAROLD C. GREENWOOD of Putney, London, England; Feb. 3, 1920.)

Synthetic Production of Sodium Cyanide.—Molten metallic sodium and nitrogen gas are introduced simultaneously into an iron vessel filled with charcoal heated to about 800 deg. C. With 784 kg. of sodium and a slight excess over the theoretical equivalent of nitrogen, 96.7 kg. of NaCN drained from the charcoal while the balance of about 1,570 kg. was retained in the charcoal mass, the latter showing an average test of about 64 per cent NaCN. The NaCN can be leached out. (1,332,-439; HANS FOERSTERLING, HERBERT PHILIPP and RALPH N. SARGENT of Perth Amboy, N. J., assignors to Roessler & Hasslacher Chemical Co.; March 2, 1920.)

Synthesis of Ammonia.—The yields in the Haber process for the production of ammonia from mixtures of nitrogen and hydrogen are increased by the use of pressures from 400 to 2,000 atmospheres as compared with pressures of 100 to 200 atmospheres used by Haber. GEORGES CLAUDE of Paris, France, has perfected an apparatus whereby these enormous pressures may be achieved in practice. The gas mixture is compressed in stages to 100, 350 and 1,000 atmospheres and is then led through heat interchangers in series in which the catalyst is placed. Owing to the high pressure, the ammonia formed may be liquefied by cooling with water between interchangers. The liquid ammonia is removed while the uncombined gases pass on to the next interchanger. When operating at 1,000 atmospheres, three interchangers in series will give a coefficient of combination of 50 per cent, whereas the Haber process does not exceed 11 to 15 per cent. The reaction is started by an electrically-heated coil, after which the heat of reaction maintains the required temperature of 500 to 700 deg. C. The nature of the catalyst is not disclosed, but it is stated that catalysts of low efficiency, such as iron, may be employed. [1,332,460; assigned to L'Air Liquide (Societé Anonyme Pour L'Etude et L'Exploitation des Procédés Georges Claude); March 2, 1920.]

Alumina.—Aluminum hydroxide is precipitated from solutions of aluminum salts (obtained from the treatment of labradorite) by heating with ammonia in an autoclave for about 8 hr. at 10 to 15 atmospheres. Precipitate formed in this manner settles readily and may be filtered by suction. The wet precipitate is now heated to a temperature between 100 and 200 deg. C. This treatment changes the precipitate from colloidal to powder form, so that the mass may be washed and filtered with ease. The filtrate may be used for the treatment of further quantities of labradorite by heating under pressure. Ammonia is evolved and the residue of aluminum silicate may be converted into a soluble aluminum salt by treatment with acid. (1,333,020; BIRGER F. HALVORSEN of Christiania, Norway; March 9, 1920.)

Current Events
in the Chemical and Metallurgical Industries

Industrial Conference Plan for Settling Labor Disputes

The Industrial Conference, appointed by the President last year to consider ways and means of preventing industrial disputes and settling differences between employers and employees, has made a final report. The machinery devised for the settlement of labor problems comprises a National Industrial Board, local Regional Conferences and Boards of Inquiry, functioning in the following manner:

1. The parties to the dispute may voluntarily submit their differences for settlement to a board, known as a Regional Adjustment Conference. This board consists of four representatives selected by the parties, and four others in their industry chosen by them and familiar with their problems. The board is presided over by a trained Government official, the regional chairman, who acts as a conciliator. If a unanimous agreement is reached, it results in a collective bargain having the same effect as if reached by joint organization in the shop.

2. If the Regional Conference fails to agree unanimously, the matter, with certain restrictions, goes, under the agreement of submission, to the National Industrial Board, unless the parties prefer the decision of an umpire selected by them.

No Interference With Production Pending Adjustment

3. The voluntary submission to a Regional Adjustment Conference carries with it an agreement by both parties that there shall be no interference with production pending the processes of adjustment.

4. If the parties, or either of them, refuse voluntarily to submit the dispute to the processes of the plan of adjustment, a Regional Board of Inquiry is formed by the regional chairman, of two employers and two employees from the industry, and not parties to the dispute. This board has the right, under proper safeguards, to subpœna witnesses and records, and the duty to publish its findings as a guide to public opinion. Either of the parties at conflict may join the Board of Inquiry on giving an undertaking that, so far as its side is concerned, it will agree to submit its contention to a Regional Adjustment Conference, and, if both join, a Regional Adjustment Conference is automatically created.

5. The National Industrial Board in Washington has general oversight of the working of the plan.

Plan Applicable to Public Utilities

6. The plan is applicable also to public utilities, but in such cases the Government agency having power to regulate the service has two representatives in the Adjustment Conference. Provision is made for prompt report of its findings to the rate regulating body.

The Conference makes no recommendation of a plan to cover steam railroads and other carriers, for which legislation has recently been enacted by Congress.

7. The plan provides machinery for prompt and fair adjustment of wages and working conditions of Government employees. It is especially necessary for this class of employees, who should not be permitted to strike.

Relies on Public Opinion

8. The plan involves no penalties other than those imposed by public opinion. It does not impose compulsory arbitration. It does not deny the right to strike.

It does not submit to arbitration the policy of the "closed" or "open" shop.

The plan is national in scope and operation, yet it is decentralized. It is different from anything in operation elsewhere. It is based upon American experience and is designed to meet American conditions. It employs no legal authority except the right of inquiry. Its basic idea is stimulation to settlement of differences by the parties in conflict, and the enlistment of public opinion toward enforcing that method of settlement.

American Association of Engineers' Convention

It has been decided that chapter representation at the sixth annual convention of the American Association of Engineers (St. Louis, May 10 and 11) will be in proportion to chapter membership. One chapter is entitled to one delegate or more, not to exceed one for each one hundred members. Each delegate is entitled to cast a number of votes equal to the number of certified and junior members in good standing in the chapter which he represents, but not to exceed 500 in all.

One of the subjects to be discussed is "The Reorganization of A. A. E. on a Business Basis." The suggestion has been made by W. W. K. Sparrow that the association employ a high-salaried paid president.

On the evening of the first day of the convention, Monday, May 10, there will be held seven group meetings for various groups of engineers. Among the subjects to be considered are:

"Getting Salary Schedules for Public Service Engineers Into Budgets," "What Part Shall A. A. E. Take in the Presidential Campaign?" "Making a Chapter a Force in the Community," "The Federal Department of A. A. E.," "Opportunities for the Engineer in Each of the Various Branches of the Profession," "Coordinating A. A. E. Activities in the State."

Senate Approves Sale of Sodium Nitrate

By accepting the House amendments to the bill providing for the distribution to fertilizer manufacturers and users of a portion of the Government's nitrate reserve the Senate eliminated all delay in the enactment of the legislation. The War Department opposed the House amendment until assured that it was the understanding of Congress that the funds derived from the sale of this nitrate would be available for the replacement of that portion of the nitrate reserve which might be used to meet the existing emergency.

War Department Defends Government Operation of Nitrate Plants

War Department officials appeared before the Senate Committee on Agriculture last week and presented arguments and data in reply to the contentions made by Frank S. Washburn of the American Cyanamid Co. The charges with which the War Department representatives took issue particularly were those to the effect that operation of the Muscle Shoals nitrate plant would be unfair to the Cyanamid company; that there would be no market for the products of the plant; that even if there were markets the products could be sold only at a loss; and that there would be no justification in reducing the stocks of sodium nitrate if the plant were operated. Issue also was taken with the recommendation by Mr. Washburn that construction work on the dam and power plant be stopped immediately; that the nitrate plant be put in standby condition ready for the production of ammonium nitrate in case of war; and that the Government hold itself in readiness to sell the plant to private interests should conditions justify.

Completion of Hydro-Electric Plant

The Secretary of War, who testified for the second time, expressed the opinion that work on the dam should be continued irrespective of whether the nitrate plant is operated or kept in standby. He based his statement on the general need of the country for additional electric power and the particular need of the section tributary to the Muscle Shoals water power. In addition he pointed out that $7,000,000 has already been expended on construction of the dam, all of which would be wasted if this project were to be abandoned. He emphasized the importance of operating the plant as a going concern in order to keep in touch with the developments in the fixation of nitrogen as well as to insure a trained organization which would form the nucleus for the expansion which would be necessary in case of an emergency.

Government Operation Does Not Violate Contract

Colonel Joyes in his testimony established that the proposal to operate this plant for the manufacture of nitrogen fertilizer materials was entirely in accordance with the present contracts in force between the Government and the American Cyanamid Co. and that there is no intention on the part of the Government of violating the contractual obligations with the company.

Replacement of Sodium Nitrate by Ammonium Sulphate

Major Gaillard testified again. He pointed out that sulphate of ammonia could replace, at least to the extent contemplated by this plant, nitrate of soda in fertilizers and instanced the fact that these two materials have sold and are selling on a competitive price basis. He brought out the relative prices of the two materials in mixed fertilizer in the past showing the steady increase in the use of sulphate as compared to nitrate.

Criticism of Production Costs

Major Gaillard also declared that Mr. Washburn's costs, which show no margin over and above operating expenses, were based on the use of steam power, which the Government did not contemplate using. He also claimed Mr. Washburn's figures contained other items not properly chargeable to operating costs. Even if Mr. Washburn's figures for the cost of production could be accepted, Major Gaillard declared, there still would be a margin of from $15 to $20 per ton of sulphate between the probable selling price and the cost of production.

Idleness Will Cause Deterioration

Colonel Burns, in an effort to disprove Mr. Washburn's contention that the plant would be just as available in case of a war emergency if kept in standby condition quoted from Mr. Washburn's testimony before the House Committee on Military Affairs in 1916 at which time Mr. Washburn stated that is was conceivable that plant of this sort could be maintained in idleness without such a degree of deterioration as to render it useless but that it was highly improbable that it would be so maintained and that a country which should rely for its powder supply upon the practically indefinite maintenance and working order of an idle plant would be taking a most extraordinary risk, which if it could be avoided, would be unwarranted and that a minor objection would be the cost of maintaing such a plant in readiness for operation, its upkeep and the interest on the idle capital. Colonel Burns reiterated that the operation of this plant would make it possible to redudce the reserve stock of Chilean nitrates by 150,000 long tons.

Availability of Ammonia Nitrogen

Dr. Milton Whitney, chief of the Bureau of Soils, testified as to the present urgent need in American agriculture of the products of this plant. He brought out the developments that must occur in the fertilizer industry in the use of inorganic nitrogen rather than of organic and of the more concentrated inorganic material. He stated that he entertained no doubt whatever that the products of this plant could be absorbed immediately in the agriculture of the country. He also called attention to the fact that while organic nitrogen, ammonia nitrogen, and nitrate nitrogen are somewhat different in their actions in the soil, that there is no such wide difference that would preclude the use of one material in the place of the other, in the absence of the other. He challanged Mr. Washburn's statement that ammonium sulphate cannot replace nitrate of soda in fertilizers.

Niagara District Industrial Association

There has recently been organized the Niagara District Industrial Association, embracing all the towns and cities of the Niagara Falls consular district and having for its object the promotion of industries in that section. With the rapid pushing forward of the hydro-electric canal and the completion of the Welland Ship Canal (on which work is soon to be resumed), an abundance of electric power and increased facilities for shipping will be made available here, and both points to a greater development of this already important industrial region. This district offers special opportunities to the following classes of industry: All manufactures of iron, steel, textiles, paper and pulp, electrochemicals, milling and refining.

It is in project to hold a three days' industrial congress in August next, for the purpose of bringing to the canal and power zone representatives of United States industries, in order to show them the advantages here in the way of power and of ocean-going transportation.

Canadian Institute of Chemistry

The Canadian Institute of Chemistry was organized last May at Montreal, and now has its headquarters at 314 Beaver Hall Hill in that city. The president is Prof. J. Watson Bain of the University of Toronto, and Harold J. Roast is secretary-treasurer. Among its objects are to develop the profession of chemistry so that trained chemists may become eligible for the growing needs of the country, to provide consultation for the requirements of the government, "to protect the public by gathering together a body of men who may be consulted with confidence," and to provide a registration bureau, social centers for chemists only and an employment bureau; also for the exchange of chemical knowledge by the organization of sections and sectional meetings.

Members are to be known as fellows and associate fellows, of whom the latter correspond to junior members, subject to approval by the council before their election to full fellowship. The requirements for fellowship are that the candidate

(*a*) be at least twenty-five years of age, a graduate of a recognized university having had a four years' course in pure or applied chemistry as his major subject, and who has been actively engaged in the pursuit of chemistry for two additional years in a responsible capacity.

(*b*) Under similar requirements in the main, if he has taken a three years' course he must show that he has had three years' additional experience in a responsible capacity in an approved laboratory.

(*c*) Lacking the requirements of (*a*) and (*b*), he must have held a position of responsibility in pure or applied chemistry for five years or more and will be examined as to his capacity by a committee of the Council. The examination may be waived in the discretion of the Council if the applicant has had eight years of such experience at the time of the inauguration of the Institute.

Associate fellowship provides for properly trained chemists under twenty-five years of age. At the last report the Institute had 113 fellows and three associate fellows, and it is announced by the secretary that "His Royal Highness, the Prince of Wales, has graciously consented to become an honorary fellow." In accordance with the British custom, fellows and associate fellows may add the letters F. C. I. C. or A. C. I. C. respectively after their names. Both men and women are eligible.

Bureau of Standards Appropriation

As finally agreed upon, the legislative, executive and judicial appropriation bill makes available to the Bureau of Standards $432,360 for salary accounts.

In addition, the bill provides $30,000 for testing varnish materials, soap materials, inks and chemicals. Another item of $10,000 is given the Bureau for work looking to the development of color standards and color measurement, with special reference to their industrial use in standardization and specification of colorants, such as dyestuffs, inks and pigments, and in paint, paper and textiles in which color is a pertinent property. The sum of $25,000 is provided for the continuation of the investigation of the problems involved in the production of optical glass. An additional $25,000 is allowed for metallurgical research. This work includes the development of metal substitutes, as for platinum.

Phthalic Anhydride May Again Be Used as Synthetic Indigo Intermediate

A new importance is being placed upon the development during the war by the Bureau of Chemistry of a method for producing phthalic anhydride. The scarcity of wood and other causes is adding materially to the cost of methyl alcohol and formaldehyde. Due to the cheapness with which phthalic anhydride is being manufactured by the Bureau of Chemistry's process, it seems probable that it will be employed in the near future in the manufacture of indigo. The wood situation is more clearly reflected in the paper market. That this scarcity is likely to continue for an extended period is indicated by the fact that English interests have just purchased, for a large sum, the English rights to the public service patent which was secured by the Bureau of Chemistry for its process.

The Bureau of Chemistry during the war developed the method of production on a laboratory scale. The process resulted in a purer product than had been made in Germany. Through co-operation with private manufacturers the process has been made a commercial success, with the result that phthalic anhydride is being produced at decreasing costs and is even being sold at the very gates of Germany. Switzerland has been a recent large buyer of the anhydride in this country. Important shipments also have been made to England, Japan and other countries.

Phthalic anhydride formerly was used as an intermediate in the manufacture of indigo, but was displaced by the use of the cheaper process, which in turn seems about to be displaced as a result of the cheapness of the new process combined with the rise in price of alcohol.

Potash From Green Sands

The Eastern Potash Corporation of New York is building a plant to make potash and fertilizer from the green sands of New Jersey. These sands contain from 7 to 8 per cent of potash, and occur in large deposits in the states of New Jersey, Delaware, Maryland and Virginia.

Their plant is located on the Raritan River Canal near New Brunswick, and is accessible by both water and rail. It covers about eighty acres, and is designed to handle 1,000 tons of green sands a day and produce 20,000 tons of K_2O and 600,000 tons of residue per year. Connected with this plant is the largest lime plant in the world, containing ten 8 x 125 ft. rotary kilns, producing 1,000 tons of lime a day.

Limestone for this plant will be quarried from the company's quarries located in the northern part of the state, where it will be crushed and then shipped by rail to New Brunswick. The company also owns the entire capital stock of the Raritan Refining Corporation, a near-by company, which has a favorable contract to refine Mexican petroleum. The Eastern Potash Corporation will use the fuel oil from this company to operate its power plants and kilns.

A contract has also been let to build a brick plant to utilize the residue, which makes a fine lime silica building brick. Capacity of this plant is to be 500,000 brick per day, and it is so designed that it can readily be increased to 1,000,000 brick per day.

The New Brunswick plant is now about 60 per cent completed and it is expected to be in operation early next fall. The cost of the plant is estimated to be about $250,000.

Society of Cotton Products Analysts to Hold Convention

The eleventh annual convention of the Society of Cotton Products Analysts will be held at the Grunewald Hotel, New Orleans, La., on Monday and Tuesday, May 10 and 11.

Besides the many matters of importance that will come up, and a number of reports and discussions, the program will include the following:

L. M. Tolman, chief chemist, Wilson & Co., "Oriental Oils."

Eugene E. Ayres, Sharples Specialty Co., "Centrifugal Recovery of Cottonseed Oil From Soap Stock."

George S. Jamieson, chemist in charge Fat, Oil and Wax Laboratory, Bureau of Chemistry, "The Composition of Cottonseed Oil."

Dr. David Wesson, chief chemist, Southern Cotton Oil Co., "The Eastman Colorimeter"; "A New Optical Method for Determining Oil in the Mill Product."

Harrison E. Howe, vice-chairman, Division of Industrial Relations, National Research Council, "The National Research Council and Its Relation to Our Society."

I. G. Priest, physicist, Bureau of Standards, "Rainbow Report on Color of Vegetable Oils."

Three sessions will be held, the first early Monday afternoon and two sessions Tuesday. Tuesday evening a real round-table gathering, in the form of a subscription dinner at the Grunewald, has been arranged.

Civil Service Examinations

The following examinations are announced by the United States Civil Service Commission:

Expert Driller. A vacancy exists in the Bureau of Mines at a salary of $3,000 to $3,600 a year. At least six years' experience in oil and gas well drilling is required. Apply on Form 2118 before May 11.

Supervising Metallurgist. The duties of this position will be to take charge of one of the mining experiment stations of the Bureau of Mines. Salary, $4,000 to $5,000 a year. Apply on Form 2118 before May 25.

Laboratorian Qualified in Photography. Applicants must have had at least three years' experience in general photographic work, two years of which must have been in photomicrographic work. They must understand rudiments of metallography and be able to etch metals and photograph their microstructure. Vacancies exist in the Navy Department at $4 to $7.20 per day. Apply on Form 1312 before May 25.

Sixth Member Society of Engineering Council

The American Railway Engineering Association has accepted an invitation from United Engineering Society to become a member society of Engineering Council. The Association has about 1,650 members and its headquarters are at 431 South Dearborn St., Chicago, Ill. Its president is Harry R. Safford, and its secretary E. H. Fritch. The excellent technical work done by the committees of this Association in many branches of railroad construction and maintenance is well known. The Association has named as its representative upon Engineering Council its president, Mr. Safford, who is a member of the American Society of Civil Engineers and Engineering Institute of Canada.

The societies now represented in Engineering Council have an aggregate membership of 45,000.

Relievin the Freight Car Shortage

The Material Handling Machinery Manufacturers Association has made the following calculation to show how co-operation will assist in relieving the existing car shortage.

In the United States there are about 2,452,000 freight cars now in use. These are rolling in trains loaded and empty only 9.03 per cent of the time. They average 11.29 per cent time loading and 11.29 per cent being unloaded, if every car is released before demurrage starts. The balance of 68.39 per cent is waste time, due to repairs, switching and unnecessary delays. One hour saved each day for each car would equal 2,452,000 car-hours per day. Dividing this figure by 24 (hours per day,) it is self-evident that the public would have over 102,000 additional cars to use through this simple saving of one hour per car per day.

This may be accomplished if every person or company loading or unloading cars will explain to the crews doing the work that every car released quickly helps each maker or manufacturer to increase his ability to get his goods quicker and at less expense. This ultimately reduces living costs for the crews and all.

Offer to Lease Muscle Shoals Nitrate Plant

A new angle in the matter of whether Muscle Shoals plant should operate was introduced by the proposals of L. T. Layton, representing the Fisheries Products Co., a $10,000,000 corporation, when he appeared before the House of Representatives committee investigating expenditures in the War Department. Mr. Layton's company is considering negotiation of a lease of part or all of the Muscle Shoals plant, with the idea of adding these operations to the company's existing fertilizer manufacturing activities. At present its principal activity is in the field of fish scrap, which it has developed as a fertilizer material, most extensively through North Carolina, South Carolina and Georgia.

This definite proposal that one company is willing to make arrangements with the Government to lease or perhaps purchase this plant seems in conflict with the claims which have been made recently that there is no available market for it or its products.

Stumpage for Tannin Extract for Sale

Plans are being made by the District Forester in Washington for the sale of approximately 150,000 cords of chestnut tannin extract wood stumpage in the Nantahala National Forest, in western North Carolina. The timber lies in Macon county along the Nantahala River and about fifteen miles distant from Andrews. Franklin is about the same distance to the east.

On privately owned land adjacent to this body of Government timber there is estimated to be approximately 200,000 cords of chestnut. This, in connection with the timber to be sold by the Forest Service, would be sufficient to maintain a moderate-sized tannic-acid plant for twenty-five years. Approximately 15,000 acres of Government lands are involved, of which 10,500 are heavily timbered.

The topography is favorable for all lumbering operations and work may be carried on practically throughout the year. A privately owned standard-gage railroad parallels the tract for some distance. Sufficient labor to operate a moderate-sized plant is said to be available from local sources.

A Few Uses of Zinc and Zinc Compounds

The inter-departmental committee of the Bureau of Standards at Washington has adopted new specifications for paint to be purchased by the Government that provide for not less than 30 per cent of zinc oxide in the pigment mixture. This material prevents chalking, insures color constancy and gives longer wear to paint. Zinc oxide has been used by the British Navy for half a century in battleship paint.

The rotating cylinders of many leading washing machines, now rapidly becoming a necessary adjunct to the American home, are made of rolled zinc. This material does not rust and therefore permits clothes being cleaned without discoloration.

Almost one-half of the compound of the best automobile tires on the market today is lead-free zinc oxide. This filler gives the tire its white color and resiliency and increases its tensile strength and durability.

Lithopone, a zinc product, is used in all flat wall finishes, wall paper and other interior decorations of the home. This material is also found in linoleum and table oilcloth, as well as being an important ingredient in surgical rubber goods and in certain hospital supplies.

According to wood-preserving experts, the railroads of the country could save 4c. each year on all ties they buy if these were treated before being placed in use. On one division of the Illinois Central in Kentucky ties treated with zinc chloride in 1903 are apparently still in almost perfect condition.

Zinc roofs have been in vogue in Europe for centuries. Their durability and the fact that zinc is a non-rusting material are qualities responsible for Europeans adhering to this type of covering for both their homes and for public buildings.

Book Reviews

THE PETROLEUM HANDBOOK. By *Stephen O. Andros, E. M.* 206 pp. 48 figs. 17 tables. Chicago: The Shaw Publishing Co. Price, $2.

While this book contains only a small proportion of original matter, it represents a careful and intelligent selection of fundamental data in regard to the petroleum industry. Facts and figures from twenty-seven standard works of reference have been brought together in the form of a connected, coherent résumé of this great industry.

The book is divided into eight chapters. The first discusses the origin, accumulation and occurrence of petroleum, the second the methods of exploration and drilling for oil and gas. Chapter III reviews briefly the methods of refining, giving flow sheets to illustrate the principal processes. Chapter IV describes the compression, refrigeration and absorption methods for the recovery of gasoline from natural gas. The shale oil industry is touched upon in Chapter V. Chapters VI and VII take up: The marketing of petroleum products in barrels, trucks and tank cars; gasoline specifications, inspection laws and marketing practices. A summary of the different state inspection laws relating to gasoline and kesosene is given in tabular form. The final chapter, "The Economic Utilization of Petroleum," illustrates the interrelation of the several factors previously discussed, in the working of a typical large progressive oil company.

Engineers, students and others interested in a brief yet accurate summary of the petroleum industry will welcome the appearance of this condensed reference book.

ALAN G. WIKOFF.

Personal

ADAM G. ADAMS, JR., who was until recently consulting engineer with the Nitrate Division of the Army Ordnance at Washington, has become affiliated with the Ashcraft-Wilkinson Co., of Atlanta, Ga., manufacturer and distributor of fertilizing materials.

A. V. BLEININGER, chief of the Ceramic Research Laboratory of the Bureau of Standards at Pittsburgh, has gone to Washington with his entire staff. A dinner and a large purse was given for Mr. Bleininger by his friends in Pittsburgh. The Ceramic Research Laboratory will be located in the new Engineering Building at the Bureau of Standards, Washington, D. C.

ELLERY K. FILES has become assistant superintendent of the pyroxylin department of the Duratex Co., Newark, N. J.

Dr. ZAY JEFFRIES will give fifteen lectures on non-ferrous metallography at the Graduate School, Harvard University, May 10 to June 1.

C. BRACE KELLY, formerly district manager of the American Sintering Co., Youngstown, Ohio, is now engineer for the American Ore Reclamation Co., with offices in New York.

E. G. REPPEL, general sales manager of the Buffalo Foundry & Machine Co., has spent a month touring the West. He left San Francisco April 24 by way of the Northwest for the East.

F. ROHDE has resigned as vice-president and general manager of the Palo Co., New York, to become president of the Rohde Laboratory Supply Co., recently incorporated.

FREDERICK J. RYAN has been elected president of the American Metallurgical Corporation, Philadelphia, Pa.

S. R. SCHOLES has severed his connection with the H. C. Fry Glass Co., Rochester, Pa., to become general manager of the Utility Glass Works, Lonaconing, Md.

Prof. ROBERT E. SWAIN of Leland Stanford University has been appointed by Federal Judge T. D. Johnson, commissioner to observe the operation of the smelters at Murray and Midvale, Utah, and investigate all complaints made as to smoke damage, reporting to the court on Feb. 1, 1921.

CLARENCE T. TODD, formerly with the Timber Butte Milling Co., is now with the engineering department of the Ray Consolidated Copper Co.

MAX ALBERT WHITING addressed the New York Electrical Society on Wednesday, April 21, on "Electricity in the Production of Iron and Steel."

ORVILLE WRIGHT is to be the recipient of the John Fritz Medal this year, at a meeting to be held in the auditorium of the Engineering Societies Building, New York City, May 7.

F. W. YOST, formerly engineer of the American Ore Reclamation Co., succeeds Mr. Kelly, resigned, as district manager of the American Sintering Co., Youngstown, Ohio.

Obituary

Dr. JOHN A. BRASHEAR, past president of the American Institute of Mechanical Engineers, died at his home in Pittsburgh, April 8, following a lingering illness.

O. J. D. THOMAS, late chief chemist of the E. B. Eddy Co., Hull, Canada, is dead of pneumonia. Mr. Thomas came from England some years ago, and, after spending some time in metallurgical work, engaged with the Eddy Co. in 1917.

Current Market Reports

The Non-Ferrous Metal Market

New York, April 26, 1920.—The domestic copper market remains quiet at 19¼c. for shipment up to August, with the outside market shading quotations to 18½c., with a very little metal to offer. The quietude is probably very largely due to the railroad tie-up. It must also be taken into account that the Butte strike has greatly lowered the production of the refineries. Lead and zinc strengthened slightly, while silver continues to fall off in price. Another break in tin dropped the price to 61½c.

	Cents per Lb.

The Iron and Steel Market

Pittsburgh, Pa., April 23, 1920.

The course of the pig iron and steel markets has been uninteresting, the markets being extremely dull. Interest centers largely upon the curtailment in steel production and shipments caused by the rail strike and the possible effect such curtailment may have.

While the general accounts of the rail strike are very favorable as to the resumption of rail movement, it chances that the iron and steel industry has had but little relief thus far. While conditions East and West have improved materially, there is little improvement in the immediate Pittsburgh district and none in the valleys. There has been considerable improvement in the Chicago district, including Gary. The Pittsburgh gateway remains practically closed. The railroads are moving some perishables and foodstuffs, but not much even of such commodities. When it comes to commodities in which the iron and steel industry is interested, the railroads offer but little outside of suggestions that solid trainloads be made up, and there is question whether much of that sort of thing would prove successful.

Production Curtailed Less Than Expected

Production in the iron and steel industry, however, has not been curtailed to as great an extent as was expected or as was estimated early in the rail strike that began about a fortnight ago. While many blast furnaces are banked and not a few works are closed or are merely "limping along," there has been operation of many furnaces and plants by unexpected or devious means. Much Connellsville coke has been moved by water. Several lines of communication have been established over public roads, closed by the strike as to normal operation, but correspondingly open if shippers or consignees had locomotives and crews they could send out to use rails that would otherwise be idle. A few furnaces have been found with stocks of coke, accumulated during the several months of restricted transportation, when everyone took all the coke obtainable irrespective of requirements.

Even should the rail strike end entirely within a few days the curtailment in production would last for some time, as return of empties will undoubtedly be slow, and the total loss of production, in pig iron and steel, may amount to nearly if not quite a week's normal production by the whole industry.

Shipments Reduced More Than Production

Shipments of steel are reduced very much more than production. While the Youngstown mills are nearly all closed, the immediate Pittsburgh district is producing a fairly large tonnage, but has been shipping scarcely any. The largest local independent managed to gather a total of about 1,500 cars, which were loaded and have gone to railroad sidings or remain on company sidings, it becoming necessary then to pile steel on the ground. The Carnegie Steel Co. has been greatly aided in keeping its mills from being choked by having its own interplant line, the Union Railroad, as well as the Bessemer road, both of which have been in regular operation except for the moving of freight off their rails.

Consumers Are Indifferent

Curtailment in shipment has not brought the consumers into the prompt market to any extent. The indifference of consumers may be due to their being likewise restricted, in their operations, to a realization that prompt steel could hardly be secured by bidding for it, or to their having greater stocks that has been assumed. This last point raises an interesting question, for widely divergent views have been expressed of late as to the interpretation of the large output the industry has had in the past three months. One view was that the large output being absorbed so readily showed that the country had unexpectedly great absorbing power, the opposed view being that all the steel shipped was not consumed, but was to a considerable degree absorbed in stocks. Time may soon tell which was the correct analysis.

Whatever may be the state of order books or the position of the market at the moment as to the level of prices or the stiffness with which they are maintained, one cannot possibly contend that the position of the money and security markets disclosed by developments of the past few days is not an important factor in making or indicating the steel market's future. In the long run the steel industry, particularly when it is 40 or 45 per cent larger than just before the war, cannot have full employment for its capacity unless a large percentage of the output passes into works of permanent construction, into what may be called long term investments. Such investments certainly are not made when financial conditions are as at present. When the underwriters of 10-yr. 7 per cent gold bonds of the Pennsylvania R.R. can offer the bonds to the public at face, it is evident that investment construction generally cannot proceed on a high level of activity.

Steel Corporation Booked Far Ahead

Light on this general subject may be thrown by consideration of the state of steel mill order books. Several of the

large independent producers state that they have not formally opened their order books for third quarter shipments, though undoubtedly they have booked considerable tonnages, with large customers, for that period, while they will probably carry over some second quarter tonnages. The smaller independents, which are quoting much higher prices than the larger independents, are of course booked still less distances ahead. The Steel Corporation alone is booked far ahead, its average date being about Jan. 15, 1921, though of course this is merely an average, the various products being sold for widely different distances ahead. That the Steel Corporation is booked far ahead is merely a reflection of the fact that its prices are lower than those of the independents, and the further fact that its customers know that, in accordance with established practice in the steel trade, they would not be expected to take deliveries such as would work a distinct hardship to the buyer. The short distance ahead to which the independents are sold is significant. It might be thought that sales farther ahead could be effected by reducing prices, but such reductions would probably discourage buyers, and the policy of independents generally seems to be that, since they have attained certain price levels, it is better to adhere to them and let the trade buy for whatever distance ahead it chooses. It seems far from improbable that a general readjustment to a safer and saner condition in business generally is about to occur, and in any such adjustment the iron and steel industry will naturally have a part. Not a few bankers have predicted a crisis for next August, hence it is reasonably certain that no such thing will occur, for an expected crisis or panic is practically impossible. Either the event will not occur at all or it will be precipitated, for an earner time, by the expectation.

Chemical and Allied Industrial Markets

New York, April 26, 1920.

General conditions throughout the list have not improved during the week; if anything the situation has become more serious than it has ever been before in the memory of those engaged in the trade. Spot material of the alkali group is being consumed faster than it arrives, producers are behind in their contracts on the heavy chemicals and all coal-tar products are practically nominal both on spot and contract. Shipments made just prior to the railroad strike are still en route and whatever material is on hand for the producer to ship is lying idle because of the lack of cars. Both foreign and domestic demand is very strong, as it has been for some time back, but owing to the above-mentioned conditions the volume of business has fallen off considerably.

PRINCIPAL PRICE CHANGES

	Today	Last Week	Last Month	Last Year
Aqua ammonia, 26 deg., lb.	$0.08½–$0.12	$0.08½–$0.12	$0.08½–$0.12	$0.06½–$0.09
Bleaching powder, cwt.	4.00 – 5.00	4.00 – 5.00	3.50 – 4.50	1.40– 2.00
Calcium chloride, fused lump, ton	22.00 –40.00	22.00 –40.00	20.00 –30.00	19.00 –20.00
Glauber's salt, cwt.	1.65 – 2.00	1.50 – 2.00	1.45 – 1.65	1.35 – 1.50
Salt cake, ton	21.00 –32.00	22.00 –26.00	21.00 –22.00	12.00 –14.00

General Chemicals

No new developments have occurred in this list, prices in general being sustained by the tightness of supplies. It is reported that producers are pretty well sold out on *calcium chloride* for future and the spot market is in a very poor way. The fused lump grade is firm at $22@$25 for car lots and $30@$40 per ton for less, while granulated came up slightly at 1½@2½c. per lb. Heavy demand on *carbon bisulphide* has tightened up. The spot market is short of supplies, and quotations vary from 9@10c. for spot, with the latter figure prevailing. Continued heavy demand both foreign and domestic has left producers in a bad way, being sold up for months ahead and unable to keep pace with contracts. The spot market is practically bare of material and as high as $32 per ton has been heard, but the average seems to be between $28@$30 per ton. With the arrival of shipments of *sodium nitrite* from Norway the situation is easier. Spot material is 22@24c. per lb. *Nickel salts* has been under heavy inquiry during the week and former quotations of 14@15c. for double and 16@17c. per lb. for single are well maintained. *Soda ash* remains in the same nominal position, with quotations varying from $3.50@$4.50 for either grade, while export demand continues brisk and grasping at all available supplies. *Bleaching powder* is practically off the market, and figures as high as $5 per cwt. have been heard during the week, but this cannot be considered the market, as there is so little material available that whatever does change hands is at a premium. The *acid* group is extremely short and business is being done on a small scale. *Hydrochloric* is wholly nominal, as there is very little material on hand. *Hydrofluoric* is in almost the same position and producers are reported sold ahead as far as three months. The 52 per cent grade is listed at 12@14c. per lb. *Oxalic* crystals under heavy demand has come up and is quoted at 55@57c. per lb.

Coal-Tar Products

Practically the same conditions prevailing throughout the chemical list exist also in tar products market. The spot shortages and transportation difficulties are possibly felt more acutely here than in any other market. There is practically no spot market on any of the items and producers are so much handicapped by the extremely heavy demand and the large decrease in production as not to be able even to conjecture when and how the situation may be made easier. *Beta napthol benzoate* remained firm, with difficulty in obtaining material. The previous listing of 50@65c. per lb. still holds. *Phthalic anhydride* is under the usual demand with one factor practically controlling the market price on this item. *Aniline oil*, under usual demand, held firm at 34@45c. with some difficulty in locating material at these figures. The *salts* are scarce on spot and 42@48c. per lb. is being asked.

Naval Stores

In naval stores the tight situation of extremely high prices, no material and heavy demand has not become any easier during the week. *Turpentine* still remains nominally quoted at $2.50 per gal., but there is no material obtainable even at this level. *Rosins* are nominal also, as there is nothing to be had in either the New York or Savannah market. These conditions will remain until the arrival of the crudes at the primary market and until such time as the transportation problem can be made easier.

Vegetable Oils

Very little activity on the part of buyers of vegetable oils has been shown during the period and on the whole the market has been very weak. *Soya bean*, in barrels, slumped and is listed at 18@18½c., against 19@23c. per lb. of last week, and tanks at 13¾c. *Cottonseed* has been weak and dropped 1½c. to 16@17c. per lb.

Miscellaneous Materials

Barytes remains in the same nominal position as was previously reported. All quotations by producers are subject to conditions at the time of shipment. There is no spot material available. Quotations of $38@$40 for white floated and $20@$25 for off color per ton still hold.

The *feldspar* situation remains unchanged, with prices of $13@$18 for ground grade, f.o.b. New York State, well maintained.

Fluorspar, gravel, f.o.b. Tunuco, Mexico, is listed at $25, while nominal prices of $30@$45 for acid grade lump, and $52@$57 per ton, for acid grade ground, f.o.b. Tunuco, still hold.

Ores and Semi-Finished Products

The Government price having been removed from coke, the price jumped from $6 to $11@$12 for furnace and from $7 to $12@$14 per ton on foundry. Due to the recent railroad strike, very little material has been moving from the Connellsville district, which makes listings practically nominal.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	.....	$0.60 – $0.65
Acetone	lb.	$0.13 – $0.15	.16 – .18
Acid, acetic, 28 per cent	cwt.	3.50 – 4.00	4.25 – 4.50
Acetic, 56 per cent	cwt.	8.00 – 8.50	8.75 – 9.00

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.40 —	.50
Aniline oil, drums extra	lb.	.34 —	.45
Aniline salts	lb.	.42 —	.48
Anthracine, 80% in drums (100 lb.)	lb.	.90 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.25 —	1.35
Benzidine, sulphate	lb.	1.20 —	1.25
Benzoic acid, U.S.P	lb.	.90 —	1.10
Benzoate of soda, U.S.P	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.31
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	25 —	.35
Beta naphthol benzoate	lb.	50 —	.65
Beta naphthol, sublimed	lb.	.70 —	.90
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 —	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.85 —	1.00
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.70
Dichlorbenzol	lb.	.08 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline (nominal)	lb.	..... —	.....
Dinitrobenzol	lb.	.30 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.34 —	.36
Dinitrotoluol	lb.	.40 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine (nominal)	lb.	.55 —	.65
H-acid (nominal)	lb.	1.90 —	2.00
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.10 —	.12
Monoethylaniline	lb.	1.70 —	1.85
Naphthaline crushed, in bbls. (250 lb.)	lb.	.08 —	.09
Naphthaline, flake	lb.	.09 —	.10
Naphthaline, balls	lb.	.10½ —	.11
Naphthionic acid, crude	lb.	.70 —	.85
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.40 —	.50
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.75 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.80 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.08 —	.12
Paranitraniline	lb.	1.00 —	1.35
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.60 —	3.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.65 —	.75
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	4.25 —	4.50
Resorcin, pure	lb.	6.25 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.50 —	.52
Salicylic acid, U. S. P	lb.	.55 —	.60
Salol	lb.	90 —	1 00

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.25 —	$0.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	1.70 —	2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.38 —	$0.39
Beeswax, refined, light	lb.	.40 —	.41
Beeswax, white pure	lb.	.63 —	.68
Carnauba, No. 1. (nominal)	lb.	.80 —	.88
Carnauba, No. 2, regular (nominal)	lb.	.60 —	.70
Carnauba, No. 3, North Country (nominal) †	lb.	.45 —	.46
Japan	lb.	.20 —	.21
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	—	.10
Paraffine waxes, crude, scale 124-126 m.p.	lb.	—	.11
Paraffine waxes, refined, 118-120 m.p.	lb.	—	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.12 —	.12½
Paraffine waxes, refined, 133-135 m.p.	lb.	.14 —	.14½
Paraffine waxes, refined, 135-137 m.p.	lb.	.16 —	.16½
Stearic acid, single pressed	lb.	.26 —	.27
Stearic acid, double pressed	lb.	.32 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.38
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$18.50	—$19.50
Rosin E-I	280 lb	19.75	— 20.00
Rosin K-N	280 lb.	20.25	— 21.95
Rosin W. G.-W. W.	280 lb.	22.00	— 24.00
Wood rosin, bbl.	280 lb.	15.50	— 18.50
Spirits of turpentine	gal.	....	— 2.50
Wood turpentine, steam dist.	gal.	2.35	— 2.40
Wood turpentine, dest. dist.	gal.	....	— 2.00
Pine tar pitch, bbl.	200 lb.	8.40	— 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	— 15.00
Retort tar, bbl.	500 lb.	15.00	— 15.50
Rosin oil, first run	gal.	.92	— .95
Rosin oil, second run	gal.	.94	— .97
Rosin oil, third run	gal.	1.10	— 1.15
Rosin oil, fourth run	gal.	1.17	— 1.18

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb	$0.40½ —	$0.42
Upriver coarse	lb.	.30½ —	.32
Upriver caucho ball	lb.	.32½ —	.33
Plantation—First latex crepe	lb.	.43 —	.44
Ribbed smoked sheets	lb.	.42¼ —	.42½
Brown crepe, thin, clean	lb.	.42 —	....
Amber crepe No. 1	lb.	.40½ —	.41½

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.19 —	$0.20
Castor oil, AA, in bbls.	lb.	.20 —	.23
China wood oil, in bbls.	lb.	.24 —	.24½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18½ —	.19
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.19 —	.20
Corn oil, crude, in bbls.	lb.	.17¾ —	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.16 —	.17
Cottonseed oil, summer yellow	lb.	.18½ —	.19
Cottonseed oil, winter yellow	lb.	.21 —	.23
Linseed oil, raw, car lots	gal.	1.84 —	....
Linseed oil, raw, tank cars	gal.	1.79 —	....
Linseed oil, boiled, car lots	gal.	1.87 —	....
Olive oil, commercial	gal.	2.75 —	3.00
Palm, Lagos	lb.	.15½ —	.16½
Palm, bright red	lb.	.14½ —	.17½
Palm, Niger	lb.	.14 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.20½ —	.22
Peanut oil, refined, in bbls.	lb.	.25 —	.26
Rapeseed oil, refined in bbls.	gal.	1.65 —	1.66
Rapeseed oil, blown, in bbls.	gal.	1.78 —	1.80
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	18 —	18½
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.13¾ —	.14¾

FISH

Winter pressed Menhaden	gal.	$1.17 —	$1.18
Yellow bleached Menhaden	gal.	1.20 —	1.22
White bleached Menhaden	gal.	1.23 —	1.24
Blown Menhaden	gal.	1.34 —	1.36

Graphite, crucible, 90% carbon content	lb.	—	.10
Graphite, crucible, 91% carbon content	lb.	—	.10½
Graphite, crucible, 92% carbon content	lb.	—	.11
Graphite, crucible, plus 92%	lb.	—	12½
Pumice stone, imported	lb.	.03 —	06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, orange, fine nominal	lb.	1.45 —	....
Shellac, orange, superfine	lb.	1.60 —	1.65
Shellac, A. C. garnet	lb.	1.30 —	1.35
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	20.00 —	30.00
Talc, imported	ton	60.00 —	70.00

Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	75-80 at Chester, Penn
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn
Magnesite, dead burned	net ton	50-55 at Chester, Penn
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.22
Ferro-manganese, 70-80% Mn.	gross ton	180.00 —	250.00
Spiegeleisen, 16-20% Mn.	gross ton	60.00 —	65.00
Ferro-molybdenum, per lb. of Mo.	lb.	2.25 —	2.75
Ferro-silicon, 50%	gross ton	80.00 —	90.00
Ferro-silicon, 75%	gross ton	150.00 —	200.00
Ferro-silicon, 10-15%	gross ton	60.00 —	65.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	.90 —	1.10
Ferro-uranium, 35-50% of U	lb.	7.00 —	....
Ferro-vanadium, 30-40% per lb. of contained V.	lb	6.50 —	7.75

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
Coke, foundry, f.o.b. ovens	net ton	12.00 —	14.00
Coke, furnace, f.o.b. ovens	net ton	11.00 —	12.00
Petroleum coke, refinery, Atlantic seaboard	net ton	.... —	14.00
Fluor spar, gravel, f.o.b. mines	net ton	25.00 —	30.00
Manganese ore, 45% Mn and over	unit	.75 —	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00 —	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00 —	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50 —	7.50
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	5.00 —	7.00
Pyrites, foreign, lump	unit	.17 —	....
Pyrites, foreign, fine	unit	.17 —	....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	....
Rutile, 95% TiO_2	lb.	.11 —	....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	....
Monazite, per unit of ThO_2	unit	42.00 —	....

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

EL MONTE—The city rejected all bids for the installation of a septic tank in connection with the proposed sewer system, here. Olmsted & Gillilen, Hollingsworth Bldg., Los Angeles, Engrs. Work will be readvertised.

Connecticut

MIDDLETOWN—W. S. Miller, 37 Washington St., has awarded the contract for the construction of a 1-story, 40 x 70-ft. manufacturing plant addition on Washington St., to D. McKenzie, 17 Allison St. Estimated cost, $18,000.

Texas

HOUSTON—The Macks Mfg. Co., Ltd., Mack St., is building extensions to its present extensive factory, here, including a 74x200-ft. steel foundry equipped with a 3-ton electric furnace, core ovens and other equipment. Charles R. Edwards, supt.

WHITESBORO—The Whitesboro Oil & Refining Co. has awarded the contract for the construction of a 2,000-bbl. daily capacity oil refinery, to Earl & Beck, St. Louis, Mo. Estimated cost, $150,000.

West Virginia

PARSONS—The O. A. Miller's Chemical Co. is in the market for bottle filling, labeling and corking machines, filters, mixing tanks, etc.

Wisconsin

CUDAHY—The Federal Rubber Co., Packard Ave., has awarded the contract for the construction of a 6-story, 100x120-ft. rubber mill, to the Leonard Constr. Co., 332 South Michigan Ave., Chicago.

MILWAUKEE—The Bernert Mfg. Co., 489-91 12th St., has purchased an 8-acre site on Atkinson Ave., North Milwaukee, and plans to build a 120x260-ft. building and a 60x100-ft. foundry on same. Joseph Glaser, archt.

MILWAUKEE — The Lindemann & Hoverson Co., 1st and Cleveland Aves., is having plans prepared for the construction of a 1-story, 60x80-ft. annealing plant on 1st Ave. Estimated cost, $25,000. Klug & Smith, Mack Bldg., engrs.

MARINETTE—The Hoskins-Morainville Paper Co. has awarded the contract for the construction of a mill, here, to the H. J. Selmer Constr. Co., Green Bay. The mill will include a 2-story, 63x80-ft. main building, a turbine house, power house and stack. Estimated cost, $350,000.

SHEBOYGAN—The Badger State Tanning Co., South Water St. and Maryland Ave., has awarded the contract for the construction of a 4-story, 105x342-ft. tannery, to the Westinghouse, Church, Kerr Co., Inc., 37 Wall St., New York City. Estimated cost, $750,000. Noted Jan. 21.

SHEBOYGAN—The Rexire Co., South River St., plans to build a 4-story, 60x200-ft. factory and an addition to present factory for the manufacture of soaps and oils. Estimated cost, from $45,000 to $50,000.

Ontario

ESSEX—The Essex Traction Co. plans to construct a 1- and 2-story addition to its factory for the manufacture of traction engines. Estimated cost, $50,000.

LONDON—The Bd. Educ. plans to build a school building, here. A chemical and physical laboratory with complete equipment will be installed in same. Estimated cost, $175,000. L. E. Carrothers, archt.

OTTAWA—The Dept. of Pub. Wks. will soon receive bids for the construction of a 4-story research institute for the Dominion Government. Scientific instruments will be installed in same. Estimated cost, $500,000. R. C. Knight, archt.

OTTAWA—The Nukol Fuel Co., Ltd., 198 Sparks St., will soon have plans prepared for the construction of a factory for the manufacture of nukol. Estimated cost, $250,000.

SARNIA—S. B. Coon & Son, archts., 36 Toronto St., Toronto, will receive bids until May 5, for the construction of a 3-story high school, here, for the Bd. Educ. Chemical and physical laboratory equipment will be installed in same. Estimated cost, $325,000. Melvern F. Thomas, 229 College St., Toronto, engr.

TORONTO—The Canadian Tygard Engine Co., Kingston Rd., has awarded the general contract for the construction of a 2-story, 50x160-ft. factory for the manufacture of carburetors and engines, to Walter Snelling. Estimated cost, $40,000.

TORONTO—The Dominion Oxygen Co., 120 Elm St., has awarded the contract for the construction of a 3-story, 60x80-ft. liquid oxygen plant on Elm St., to Wells & Gray, Confederation Life Bldg. Chemical equipment for oxygen generation will be installed in same. Estimated cost, $75,000.

TORONTO—The Photo Engravers Ltd., 70 Bond St., has awarded the general contract for the construction of a 3-story, 60x80-ft. photo engraving building, to T. E. Essery, Confederation Life Bldg., at $80,000.

WOODSTOCK—The city has awarded the contract for the installation of filtros plate, in connection with the proposed sludge plant, here, to the General Filtration Co., Cutler Bldg., Rochester, N. Y., at $4,551.

Quebec

MURRAY BAY—The Murray Bay Power and Pulp Co. plans to construct a plant here. Estimated cost, $500,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its sixth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold regular meetings on May 7 and June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18, inclusive.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK announces the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theater: "Modern Coke and Gas Manufacture" (Koppers process), Thursday, April 29, at 4 p.m., E. L. Crowe (*Lantern and cinema*); "Chemical Naval Warfare," Friday, May 7, at 4 p.m., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 p.m., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA plans to hold its annual convention in the Auditorium Theater, Chicago, Ill., May 19, 20 and 21.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E., will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect. The autumn meeting of the Iron and Steel Institute (British) will be held at Cardiff, by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE MINE INSPECTORS' INSTITUTE OF AMERICA will hold a meeting at Cleveland, Ohio, July 13, 14 and 15.

THE MINING SOCIETY OF NOVA SCOTIA has planned a meeting for May 4 and 5, which will be held in Glace Bay.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 and 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE NEW JERSEY CHEMICAL SOCIETY plans the following: Monday evening, May 10, regular meeting; Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J., regular meeting and ladies' day.

THE SOCIÉTÉ CHIMIE INDUSTRIELLE will hold a meeting at the Chemist's Club, May 14.

THE SOCIETY OF COTTON PRODUCTS ANALYSTS will hold its eleventh annual convention at the Grunewald Hotel, New Orleans, La., May 10 and 11.

THE SOCIETY OF CHEMICAL INDUSTRY, American Section, will hold a meeting, May 21, at the Chemists' Club.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

Industrial Notes

C. C. MCDERMOTT has succeeded J. W. Lazear as district manager of the Chicago office of the Brown Instrument Co. of Philadelphia. Mr. McDermott has been transferred from the Philadelphia office, where he was district manager for some time.

THE CHICAGO PNEUMATIC TOOL CO. transferred its general office from Chicago to New York City on March 31. The new quarters of the company are in a 10-story structure erected for its exclusive use at 6 East 44th St. At the same time the Chicago district sales branch, formerly in the Fisher Bldg., was moved to 300 North Michigan Boulevard. The Chicago service branch, formerly at 521 South Dearborn St., has been consolidated with the sales branch at the new address, where both are under the direction of J. S. Canby, district manager.

THE YARNALL-WARING CO., Philadelphia, announces that D. T. Newman, formerly connected with the Philadelphia sales office, has been placed in charge of its Atlanta, Ga., office, recently opened in the Candler Annex.

THE COOPER UNION FOR THE ADVANCEMENT OF SCIENCE AND ART, New York City, announces a new day course in industrial chemistry opening Oct. 4, 1920. The course will cover a period of four years. It is intended that the instruction provided shall be eminently practical and thoroughly scientific and that it will furnish adequate equipment for young men and women who desire employment as analysts, production foremen, research chemists, engineers, factory superintendents, purchasing agents, and in other phases of industry which call for persons with chemical training.

THE TABER PUMP CO., Buffalo, N. Y., maintains a resident representative in Chicago in the person of G. T. Schushan, with office at 410 Cunard Bldg.

THE PLAN FOR THE MERGER of Westinghouse, Church, Kerr & Co., Inc., and Dwight P. Robinson & Co., Inc., recently submitted for the approval of the stockholders of these companies, has been declared operative by the committee appointed in accordance with plan. At a meeting of the board of directors of Westinghouse, Church, Kerr & Co., Inc., Dwight P. Robinson was elected president of that company, pending final completion of the merger and organization of the new company. General Guy E. Tripp, now chairman of the board of Westinghouse, Church, Kerr & Co., Inc., retains this position pending completion of the merger. The Westinghouse Electric & Manufacturing Co. is one of the largest stockholders of Westinghouse, Church, Kerr & Co., and the two companies have been closely identified for many years. To avoid what has seemed a handicap in procuring business by the latter company, on account of the belief by prospective clients that if they employed it as their construction engineer, they might be expected to purchase Westinghouse electric equipment, and also to permit the Westinghouse Electric & Manufacturing Co. to withdraw from any

interest in the engineering and construction business, it was deemed in the interest of both companies that the association should be terminated. To accomplish this without embarrassment to other stockholders, and to their advantage, negotiations were initiated with Dwight P. Robinson, president of Dwight P. Robinson & Co., Inc., looking to a merger of Westinghouse, Church, Kerr & Co. with Dwight P. Robinson & Co., Inc. These negotiations resulted in the plan of merger now declared operative, under which depositing stockholders will receive for their present holdings either cash or stock in the new company.

THE RESEARCH CORPORATION announces the removal of its offices to 31 West 43rd Street, New York.

THE ELECTRO-ALLOYS Co., Elyria, Ohio, has been formed to take over and manufacture certain alloys developed by F. A. Fahrenwald. The initial product will be chiefly a high-temperature alloy in the form of heat-treating and other apparatus requiring resistance to oxidation at high temperatures. These high-temperature products will be marketed under the trade name—"Thermalloy." The electric foundry will be in operation about May 1.

THE BARBER-GREEN Co., Aurora, Ill., has found it necessary to make certain additions and changes in its selling organization due to the rapid growth of the company and the demand for B-G self-feeding bucket loaders and standardized belt conveyors. It is represented in St. Louis by R. E. Foulke, 404 Third National Bank Bldg.; in Pittsburgh by J. A. Gurney, 605-606 Arrott Bldg.; in Philadelphia by F. S. Sawyer, 1010 Penn Square Bldg.; in Indianapolis by W. T. MacDonald, 305 Merchants Bank Bldg.

THE ROVEY INSTRUMENT & CHEMICAL Co. has been incorporated in Buffalo, N. Y., by George G. Stuart, of Cleveland, Ohio, district salesmanager for the Youngstown Sheet & Tube Co., John S. Rovey, former purchasing agent for the Buffalo Apparatus Co., and Mrs. James M. Gisel, with a capital stock of $25,000. The concern is located at 75 Niagara Sq., Buffalo, N. Y. For the present it will act as sales agent, although Mr. Rovey announces that it is the idea of the incorporators to engage in the manufacture of industrial and commercial and laboratory instruments.

THE PHILADELPHIA TEXTILE MACHINERY Co., Philadelphia, Pa., announces its change of name to Proctor & Schwartz, Inc. The change is in name only, as the management, finances, policies, etc., remain as before.

WHEELER & WOODRUFF, chemical engineers, 280 Madison Ave., New York, announce the opening of a research and chemical engineering laboratory at 236 East 151st St., New York. The following chemical engineers and chemists have recently joined the organization: James F. Walsh, chemical engineer, lately Lieutenant in the Chemical Warfare Service, in charge of the charcoal development at the Astoria plant of the Gas Defense Division. Before entering the service Mr. Walsh was employed as chemist by the Goldschmidt Co., the Bosch Magneto Co., Borden's Condensed Milk Co. and the Otis Elevator Co. George Urquhart, chemical engineer, lately Captain in the Chemical Warfare Service, assigned to the chemical manufacture and development section of the Gas Defense Division. Before entering the service Mr. Urquhart was employed by the Solvay Process and Semet-Solvay companies at Syracuse, N. Y. William A. Jarrett, chemist, lately Lieutenant in Infantry, U. S. Army. Before entering the service Mr. Jarrett was employed as chemist by the Horton Ice Cream Co., New York. Walter C. Spiess, chemist, lately in the Gas Defense Division of the Chemical Warfare Service. Before entering the service Mr. Spiess was employed as chemist by Baker & Co., Inc., Newark, N. J.

THE METAL & THERMIT CORPORATION, New York City, N. Y., in order to more adequately take care of its rapidly increasing business in the New England States and in Canada, has appointed James G. McCarty manager of its Canadian branch, with headquarters in Toronto, and has transferred Robert L. Browne from its New York office to Boston, where he will have charge of all sales in the New England States.

THE STEPHENS-ADAMSON MFG. Co., Aurora, Ill., announces the opening of a new branch store, assembling shops and sales office at 412 East Third St., Los Angeles, Cal. This office will be under the direction of R. C. Pierce.

JOSEPH T. RYERSON & SON of Chicago and New York, and the Camden Iron Works, Camden, N. J., announce a new selling arrangement whereby Joseph T. Ryerson & Son become representatives of the Camden Iron Works in the sale of its hydraulic machinery products. Joseph T. Ryerson & Son have been in business for the past seventy-eight years, with their main warehouse plant and general office at Chicago, branch plants at New York, Buffalo, Detroit and St. Louis, and sales offices in the larger cities in the United States. They also have a foreign selling organization, with representatives in Europe and the Orient. The Camden Iron Works is also an old-established manufacturing concern, and in addition to a complete line of hydraulic tools, is a builder of centrifugal pumps, cast-iron pipe and fittings, gas holders and kindred products.

THE NITRATE AGENCIES Co., a subsidiary of W. R. Grace & Co. of New York, is building a $250,000 plant at Bergen Point, Bayonne, N. J., for the manufacture of dyes, disinfectants, intermediate and spraying materials. The four-story building will be of hollow tile, reinforced-concrete construction, with 36,000 sq.ft. capacity. An additional warehouse of 20,000 sq.ft. floor space is also planned. The Elliott C. Brown Co. of New York has the contract for erecting the plant. Production and sales department will be in charge of Mr. Goulard. Dr. Joseph L. Turner is the technologist. The plant is expected to be in operation next September.

H. H. HARRIS, formerly general sales manager for the Swedish Crucible Steel Co., has been appointed manager for the department of heat-treating equipment of the Quigley Furnace Specialties Co., 26 Cortlandt St., New York City.

THE SOUTHERN LABORATORY SUPPLY Co., which has opened offices and warehouse in Birmingham, Ala., is the first laboratory supply house to locate in the South. For years the need of such an institution has been apparent and the establishment of this pioneer enterprise in Southern territory has met with the approval of the business and industrial interests of this section. The executive heads of the compay are Charles W. Hogg, president, and George B. Meanor, Jr., vice-president, both formerly of Pittsburgh, Pa.

THE THERMAL SYNDICATE, LTD., New York City, announces that W. Earle Strevig, formerly of the New York office, is now its Pittsburgh-Cleveland representative. He can be reached at 71 Crafton Ave., Crafton, Pa.

THE GUARANTEE BATTERY CORPORATION, of 1830 Blake St., Denver, Col., has recently been organized for the manufacture of automobile storage batteries. A part of the plant is already operating in the capacity of thirty-six batteries per day. This will be increased to eighty-five about May 1. George W. Brayfield is president, and Harry C. Brayfield secretary-treasurer. Earl B. Gandy is general manager and director of sales.

WILLIAM M. TAYLOR announces the formation of the HAMMOND INDUSTRIAL LABORATORIES, with offices at 80 Maple St., Hammond, Ind. These laboratories will specialize in the purification of water for industrial purposes and in the analysis of tanning materials. Mr. Taylor has been chemical engineer for the Kenicott Co., chemist for Montgomery, Ward & Co., chief chemist for the Refinite Co. of Omaha, and of Paige & Jones Chemical Co. of New York and Hammond, Ind.

THE NATIONAL LUMBER MANUFACTURERS ASSOCIATION has removed its general offices to the McCormick Bldg., 332 South Michigan Ave., Chicago, Ill.

WALLACE & TIERNAN Co., INC., manufacturer of chlorine control apparatus for water and sewage purification and industrial uses, announces that Harold S. Hutton has been appointed district sales representative with headquarters in the Commonwealth Bldg., Pittsburgh, Pa. Mr. Hutton succeeds P. O. Collins, who has been given indefinite leave of absence on account of illness.

D. R. SPERRY & Co., manufacturers of filter presses at Batavia, Ill., have added a department to the factory, which is turning out filter cloth and fabric, and are now prepared to ship either sewed cloth or rolls. This company also has added to the foundry equipment, which is now double its former capacity.

THE CHICAGO ASSOCIATION OF COMMERCE has organized a convention bureau, with headquarters at 10 So. LaSalle St., which will function to procure hotel accommodations for business men visiting the city as well as those desiring to stay over long periods. Crowded conditions during convention periods will be obviated.

THE MORSE CHAIN Co., Ithaca, N. Y., has moved its offices from Greensboro, N. C., to 404 Commercial Bank Bldg., Charlotte, N. C. George W. Pritchett, Southeastern manager, has found this change advisable owing to the increase in use of Morse silent chains in the textile industry.

Manufacturers' Catalogs

THE AUTOMATIC PRIMER Co., 420 Conway Bldg., Chicago, Ill., has just issued a leaflet describing a new automatic primer for centrifugal pumps.

THE CALORIZING CORPORATION OF AMERICA, Detroit, Mich., has issued a handsomely illustrated booklet, "The Protection of Metals from Oxidation at High Temperatures," which deals with protective coatings, the development and application of calorizing, and contains an appendix of useful tables. The de luxe edition is bound in flexible leather and shows a colored scale for heat measurement.

THE ELECTROLABS Co., Pittsburgh, Pa., is issuing a pamphlet on Levin Oxy-Hydrogen cells. It also announces that it offers complete plants for the production, distribution, compression and utilization of oxygen and hydrogen gases, and can, through its own manufacture supply all the necessary accessory equipment. Actual photographs of plants in operation and letters from manufacturers are included.

THE NORTON Co., Worcester, Mass., has issued three booklets, entitled "How to Order Grinding Wheels," "Grinding Wheel Stands in the Machine Shop," and "The Norton Razor Hone."

THE H. S. B. W. COCHRANE CORP., Philadelphia, Pa., formerly the Harrison Safety Boiler Works, has issued a book describing the hot process water softener. The hot process softener is a modern development of the well-known lime-soda process, the difference being that the chemicals are added to the water only after it has been heated to 205 deg. F. or higher, which results in practically instantaneous and complete chemical reactions and in more rapid settlement of the precipitate. The result is a considerable reduction in the time required for the sedimentation so that the apparatus can usually be installed within power plant buildings and without requiring special foundations or housing. The fact that a feed water heater is combined as part of the apparatus also reduces the complication and the expense of piping, etc. It is also claimed that the maximum reduction of scale- and sludge-forming matter is obtained with a minimum excess of reagents and that there is no after-precipitation or troublesome deposits of scale and sludge in pumps, piping, feed-water heaters and boilers, while, due to the reduced solubility of the products in hot alkaline water, the minimum amount of sludge-forming solids enter the boiler and the tendency to priming and foaming is minimized. In the present publication these statements are supported by scientific data and by the results of practical operation. An improved type of a chemical feeder designed to force the water into the softener against back pressure, and a system of pressure filters, are also described. The closing chapter enumerates the impurities found in boiler-feed water and describes the kinds and amounts of chemicals necessary for their removal. The book will be of value to all who are concerned with the operation of steam boilers.

THE CELITE PRODUCTS Co., 11 Broadway, N. Y., is issuing an interesting bulletin known as B-6a, describing the insulation construction of different types of boilers. The bulletin is illustrated with diagrams and views of various installations.

THE DEISTER CONCENTRATOR Co., Fort Wayne, Ind., calls attention to its latest catalog, No. 5, illustrating and describing the Deister-Overstrom diagonal deck tables.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., is distributing a catalog entitled "The American Trolley Carrier," which is an economical one-man method of handling coal ashes and like material. The equipment consists of an overhead trolley, operated on either a monorail track or suspension cable. A hoist is used to lower and move a 7-ton, self-dumping bucket, in which the material is carried. One man handles the carrier in all its operations—loading, hoisting, conveying, dumping and returning the bucket. He is not obliged to leave his station at the hoist at any time. An average of 30 tons of coal can be handled an hour. Five or six cars can be emptied during the day. The cost per ton of coal handled is extremely small, 3c. or 4c. as contrasted with the usual 18c. or 20c. entailed. Copies will be sent to interested readers on request.

THE BARNSTEAD STILL & STERILIZER Co., Boston, Mass., and Chicago, Ill., has issued a catalog on Barnstead patent water purifier and still.

The Report of the Industrial Conference

THE report of the Industrial Conference called by the President, issued a few weeks ago, apparently has received little public comment despite the fact that it offers a definite plan for the prevention of disputes and adjustment of differences now so prevalent in industry. This Conference was more successful than its predecessor, which was disrupted when Mr. GOMPERS withdrew with the representatives of Labor. The failure of that first Conference was inevitable because the groups composing it were directly interested in securing official recognition and adoption of partisan policies which were already bones of contention in industrial relations. Further, the proceedings were public. There was too much incentive to play to the galleries, and unyielding partisanship finally wrecked a hopeless attempt to formulate a constructive program.

The second Conference seems to have been more rational in its organization and procedure, and its report gives evidence of calm study, sober second thought and freedom from partisan hysteria. An effort has been made to gather facts, to learn from practical successful experience, and to formulate general policies, leaving the details to be worked out in accordance with the peculiar conditions surrounding individual industries.

For preventing industrial strife the plan which the Conference indorses is to secure co-operative effort through a "joint organization of management and employees." The Conference would prefer to "diminish the field of arbitration and enlarge the scope of voluntary settlement by agreement." And since the form of employee representation may vary in every plant, the subject "is not a field for legislation," but for local adoption and individual administration. "The strategic place to begin battle with misunderstanding is within the industrial plant itself."

The Conference is led to support the general proposition of a joint organization of management and employees because it finds that wherever such organization has been "undertaken with sincerity and good will" it has a record of success. This successful experience, the Conference believes, "is more useful than the views of extremists on either side." In case co-operative effort is not successful in reaching a collective agreement in any particular case, the Conference proposes a system of settlement through three bodies: A National Industrial Board, Regional Conferences and Boards of Inquiry, all under "governmental encouragement." "The entrance of the Government into these problems should be to stimulate further co-operation."

Opposition to the idea of employee representation is found by the Conference in two sources. On the one hand is the unprogressive and unenlightened employer, whose tribe fortunately is decreasing, who still regards labor as a commodity and who balks at any form of co-operation with his employees. On the other, there is the narrow trade-union leader who looks upon shop representation as something inimical to the union and likely to supplant its authority. As the Conference points out, however, the distorted view of the employer is rapidly disappearing, and the fear of the labor leader is based on a misconception of the relations between shop committees and unions, which are in fact complementary. "Local problems fall naturally within the province of shop committees. No organization covering the whole trade and unfamiliar with special local conditions and the questions that come up from day to day is by itself in a position to deal with these questions adequately."

The Conference recognizes fully that "employee representation offers no royal road to industrial peace. . . . It is only a means whereby sincerity of purpose, frank dealing and the establishment of common interests may bring mutual advantage." Too much stress cannot be laid on the prerequisite of sincerity of purpose in putting such a plan into effect. It is the cornerstone of all institutions involving human relations, for suspicion will defeat the ends of ideal plans. In view of the fact that the Conference discovered enthusiastic approval among employers and employees who have had experience with co-operative effort, we may accept its recommendations as representative of both parties in industrial relations. And as for the proposed system of settling disputes not agreeably disposed of through collective effort, it seems worth a trial, since "its basic idea is stimulation to settlement of differences by the parties in conflict, and the enlistment of public opinion toward enforcing that method of settlement."

A "Carnival of Greed and Imposition"

ELBERT H. GARY has been chairman of the United States Steel Corporation since its formation nineteen years ago, and has had occasion to make many public utterances, which have obviously been delivered only after careful consideration. In no such utterance has Judge GARY ever used intemperate language, and rarely has he used what might be denominated "strong" language. He has a way of having the thought expressed stronger than the language used in its expression. When, therefore, in his formal address at the recent annual meeting of the stockholders of the corporation Judge GARY referred to there being a "carnival of greed and imposition," the expression must be taken as representing a very strong conviction upon an extremely undesirable state of affairs. Judge GARY felt it to be everyone's duty, even at some personal

sacrifice, to help check the carnival. The United States Steel Corporation has been doing what it could, by continuing to sell its steel products at the March 21, 1919, prices, set by the medium of an agreement between Secretary REDFIELD'S Industrial Board and representatives of the iron and steel industry. For months past consumers of steel have been bidding higher prices and the independent producers have been asking and accepting higher prices, sometimes very much higher prices.

There are several reasons why sellers should endeavor to hold prices down in a time like this. One reason is that great injustice is worked by advancing prices, as Judge GARY clearly pointed out, to those with more or less fixed incomes, like salaries, for in essence such people are paid in a depreciated dollar.

Another reason, more or less selfish, is one that does not concern the United States Steel Corporation, since it is self-contained. That is that when a manufacturer advances his selling prices those who sell his raw materials to him are likely to advance their prices, and the manufacturer cannot "get away" with all the extra profits his own price advance seemed to assure him. It is recent history how the merchant blast furnaces greatly advanced their pig-iron market, whereupon the Lake Superior iron-ore producers advanced their ore prices and the Connellsville coke producers advanced their coke prices. The merchant furnaceman has no assurance that his advanced pig-iron market will last as long as the advanced ore and coke markets.

A third reason for holding prices to a safe and sane basis is that "whatever goes up must come down." When prices come down, usually somebody gets hurt. The proper course of business is certainly disturbed. We want to make progress, and efficiency in making progress requires that there be steady markets and uniform conditions, so that men can plan ahead and build ahead.

When there has been a great disturbance unpreventable by business interests, such as the late war, business should protect itself from the after effects. When the Great War closed there was a disposition to look at the course of industry and markets after our Civil War to see if some light might not be secured. It was unsafe then to conclude that conditions had much in common, but at this time, nearly a year and a half after the Armistice, evidence has accumulated that there is no small degree of similarity. The similarity is not a synchronism, but one should not ask for time similarity, since a month nowadays does not mean the same compass of business experience as it did over a half century ago, in the post-Civil War times. The history of that time was that after LEE'S surrender, April 9, 1865, ending the Civil War, pig iron declined for a few months, approximately from $48 to $35, then advanced to $51, a higher price than obtained at the end of the war, and then declined again. The second low point fell thirteen months after LEE'S surrender. We are slower in these days, or our business is more ponderous. There were five clearly marked round-trip swings in the pig-iron market before the continued decline set in during the great industrial depression of 1873 to 1878. It seems reasonable to assume that the fluctuations were disadvantageous to business, just as wide fluctuations are today.

If anyone assumes that prices can be pushed up and held up long enough to prove profitable, as compared with conditions under a stable and reasonable market, he is probably wrong. The worm will turn. If he assumes that there is only one advance possible and that on the basis of enlightened selfishness as much as possible ought to be made out of the advance, he is probably wrong again. Prices pushed too high eventually decline too far, and then they advance again. The present is not the last chance that is going to be afforded this generation to make money.

Either on the basis of reasonable regard for the general good or on the basis of enlightened selfishness the course dictated is that of moderation in the naming of prices for commodities or charges for service. The "carnival of greed and imposition" is probably a psychological reaction from the war-time sacrifice and co-operation. Instead of continuing the good work, we have had a reaction.

Testing High-Speed Steels In the Small Shop

A CASUAL reader may wonder just how "metallurgical engineering" can be stretched to cover the subject of lathe tools. But the metallurgist in the progressive manufacturing establishments of today realizes as keenly as does any confirmed efficiency expert the need of dependable, uniform quality of tools, and it is ordinarily he who puts the most thought and care upon them. As long as a fairly good tool is available in quantity, the men in the shop do not have much to say, but the metallurgist or heat treater is the first man to hear about any serious breakdown on account of tools. On the other hand, he is the man most actively interested in —one might almost say the only man continually seeking—a method whereby really superior tools may be secured for each class of work passing through the shop in large volume.

He has a continual problem, however, to determine to his own satisfaction whether a change in his practice will actually improve the efficiency of his product. Certain it is that relief may not infallibly follow a change in tool steels, for Major BELLIS quotes the Springfield armory as one shining example where attention to infinite detail regularly produces the most extraordinary rifle-barrel drills from mushet steel, which any salesman will tell you is obsolete, a relic of the dark ages, and even bolshevik to think about. Yet the same salesman would be hard put to make a drill from his pet brand which is half as good; perhaps BELLIS could do it, given time, but the salesman certainly not.

Inquiry among the mechanics, tool room men and shop foremen as to what they "think" of a certain brand of steel or kind of tool is admittedly a very insecure method of judging their real quality. Yet the metallurgist who has read FREDERICK W. TAYLOR'S monograph "On the Art of Cutting Metals" (and who has not?) will be so impressed with the almost overwhelming resources needed to test the efficiency of a particular tool in TAYLOR'S exhaustive manner that he will realize its impossibility of widespread application. Yet some accurate, experimental basis is essential for progress.

Mr. LANGHAMMER'S articles commencing on page 829 of this issue have within them the potentiality of enormous advance in tool steel practice, simply because they point out how the metallurgist, tool man and heat treater in the thousands of progressive but small shops may continually improve their methods with a corresponding reflection in the total costs. Of course, a large volume of ideally uniform material to be cut is seldom available

sufficient to compare so large a number of tools as did the Packard company. But the problem before the smaller shop is not so much whether they should change their brand. In fact if they are securing their stock from one of the American tool-steel makers whose every effort is for a quality product, they had far better turn a deaf ear to the persuasive salesman and attempt to develop the inherent possibilities of their regular tools. So their problem is much simplified. It is merely this: Will this small change in one detail of hardening-room practice, or tool-grinding practice, or any one of the dozens of factors responsible for a good steel, *actually improve the tool?*

It is only necessary to make up carefully two sets of, say, six tools each; one set by the standard method and the other set by the revised method, reference them by complex code markings, lay them aside and forget the code. Then watch the work going through the shop, and some day when a long job appears, carefully inspect the rough metal to be worked and select enough of it for its uniformity to cause failure in the dozen prepared tools in both first run and after regrinding. Put this work on a first class machine, work out correct conditions of operation as explained by Mr. LANGHAMMER, do the work with most careful, conscientious workmen, and make a correct log of the run.

At the end you will have something more than "opinion" to tell you whether it is better to draw from 1,100 or from 1,050.

Research Among The Bakers

THE American Institute of Baking, the first child of the National Research Council, if we are not mistaken, has duly appeared in Minneapolis, and, to judge by its first bulletin, it seems to be of requisite weight, to have lusty respiration, to possess the right number of fingers and toes—in short, to be a promising infant. Dr. H. E. BARNARD is the director, and his name gives confidence in the wisdom and scholarship of its management. It has found asylum with the Dunwoody Institute, a continuation school in Minneapolis, and here the American Institute of Baking will maintain scholarships and provide for six months' courses for bakers against the payment of fees, as well as conduct research and give consultation to its members. The president is GORDON SMITH of Mobile, Ala., and the secretary is DR. P. CHISHOLM, of Chicago.

Here is a chemical industry that has not known itself as such. It is ancient of days, replete with traditions, and complete knowledge and understanding of the art was supposed to be well-nigh universal. In fact, some of us who can hark back a generation or more recall the sage advice not to marry a lass unless she can bake a loaf of bread—and bake it well. If there was any place where the chemist was not wanted it was in the bakery—and save in rare exceptions he stayed away. The Research Department therefore finds itself confronted with chemical, physical and biological problems in remarkable number. They are complex as well as numerous, and, in the words of the bulletin, "The selection of any one of them will lead to many unknown investigations, the nature and value of which cannot be predicted. Some of these subsidiary problems may be of practical value and others may have for the present but the interest of a problem in pure science." Among the immediate projects are: The determination of moisture retention in bread and the prevention of staleness, the study of sweetening agents, shortening agents and their effects on fermentation, the activation of ferments to expedite rising, development of control tests for bakeries without laboratories, and, in co-operation with other laboratories, the study of standard and uniform methods of analysis of flour and other baking materials. In addition to these are questions of flavor, yeasts and yeast-foods to be determined—and all this is merely a beginning.

The technical and service department will offer to bakers the rapid solution of momentary difficulties and supply information on technical or chemical questions. The baking laboratory is prepared to make bread by almost any method of procedure, and an engineering bureau will give attention to questions of building construction, power, heating, ventilation, wrapping, etc. It is planned to make chemical surveys of stocks of raw materials and to keep a watchful eye for fraud and upon nostrums that are offered to the trade.

A questionnaire is included in the bulletins to which members are invited to reply. We venture to predict that the answers to question No. 8 will be an index of the scientific measure of the minds of the bakers who compose the organization. It reads: "What is your formula for the bread which is your best seller?" We wonder how many bakers there are who have enough scientific understanding to know that it will do them no harm to tell? Or that thousands of others know as much of the technique of baking as they do? Or that, scientifically considered, they are still outside the portals of knowledge? Or of the delectable gardens of profit that are available to the *cognoscenti*?

Availability of Nitrate And Ammonia Nitrogen

IN ACCORDANCE with a policy outlined in these pages some time ago, a thorough survey is being made of the fixed inorganic nitrogen industry. During the controversy over the proposed Government operation of the Muscle Shoals plants, a question has been raised which seems to be of fundamental importance in a consideration of the fixed inorganic nitrogen situation. This concerns the relative availability of nitrate and ammonia nitrogen.

This is, of course, a problem in plant metabolism, and we must turn to the agricultural chemist for reply. The commonly accepted view is that nitrate nitrogen is immediately available for plant use, while ammonia nitrogen becomes available only after it has been oxidized to nitrate by the action of certain micro-organisms in the soil.

No classical study has been concluded giving the soil and temperature conditions under which the nitrifying bacteria function. Before the days of Chilean saltpeter, almost every farm in Europe had its niter leaching bed, but the temperatures were high in these due to the heat of fermentation. Such favorable thermal conditions are seldom encountered in the present-day application of inorganic ammonium salts. This is especially true in the more northern localities. Here exists an opportunity for the bacteriological and agricultural chemists to co-operate in the isolation and study of these important bugs. The development of a more hardy type having a thermal range of activity coincident with that of plant life is not beyond the bounds of possibility.

British Chemical Industry

(From Our London Correspondent)

London, April 7, 1920.

THE past month has not been distinguished by any outstanding feature of interest, but the flood of new capital issues has practically ceased, probably because the uncertainty of the international and financial situation has made it more difficult to make underwriting arrangements. The chemical industry, which in the past has been singularly immune from difficulties arising out of strikes and labor unrest, is now passing through a transition period in which successive demands for increased wages and better conditions are being made by the workpeople. It is difficult, if not impossible, in some cases to improve the somewhat unpleasant conditions of labor obtaining in chemical factories, and on the whole grievances of this kind are being successfully met. The question of wages is proving a more difficult proposition, chiefly because the workmen's delegates are adopting the policy of making fresh demands as soon as possible after agreement has been reached on a previous claim. In the result much time and effort on the part of the executives are being wasted which could be more profitably utilized.

In the chemical trade demand still exceeds supply, especially for export account, and prices therefore remain steady and firm. Bleaching powder is practically unobtainable, and there is evidence that attempts are being made to create a temporary monopoly in cream of tartar, which is talked up to £400 per ton, as against the present price of about £300. It remains to be seen whether the increasing use of substitutes, such as acid phosphate of calcium, will have a deterrent effect, but until fresh supplies become available after the summer the outlook in this and kindred commodities is somewhat obscure.

Colloidal Fuel Development—Sugar Industry—Prospects for Synthetic Indigo

An interesting new issue is the Liquid & Solid Fuels Co., Ltd., with which, it is understood, the Duckham and Anglo-Persian interests are to some extent identified. It is rumored that this company is to exploit the patents of Lindon W. Bates and his associates, who, it will be remembered, did such valuable work for the Submarine Defense Association of America during the war. It is thought that there will be a vigorous development in the colloidal fuel field, possibly in conjunction with the provision of bunkering stations on the trade routes supplying colloidal fuel to ocean-going steamships instead of fuel oil. The position is somewhat obscure at present, as the patents have not yet been published, but it is known that there are other workers in the field in regard to suitable "fixateurs," so that in a few months' time the position should become extremely interesting. As the British Government has a large interest in the Anglo-Persian Oil Co., the problem is likely to become a national one, while at the same time industrial users are not overlooking the possibilities of this new fuel.

Another industry which is attracting increasing attention is that exemplified by Home Grown Sugar, Ltd., which, under government auspices, is to establish the beet sugar industry in Norfolk. The production of sugar within the British Empire was the subject of a report to the Society of Chemical Industry published in its *Journal* of Aug. 15, 1919, and while some years must elapse before definite results are available, it is hoped that this move will have a stabilizing effect upon the upward trend of sugar prices in this country.

The Indian indigo industry is again attracting attention as a possible competitor of synthetic indigo, a curious reversal of the situation at the time when the synthetic manufacture was perfected in Germany. The prospects of the industry are stated to be increasingly favorable since scientific investigation and methods have been applied and it was found that the use of phosphate fertilizers greatly increased production, while the alkaline action of the cement-lined tanks had an adverse effect on yields. Natural indigo is a more effective dye than the synthetic product, probably because it contains ingredients other than the indigotin which is its main constituent and is the pure material made by the synthetic process.

Trade and University Activities

The projected association of merchants, in which the lead is being taken by the larger and old-established firms, is expected to take definite shape very soon, but it is still a moot point whether an entirely new organization is to be created or whether an amicable arrangement can be arrived at with the existing British Chemical Trade Association. In this case it is interesting to note that the honorary secretary of the latter body, S. J. C. Mason, who represents an American firm, has resigned, and the assistant secretary, O. F. C. Bromfield, has been appointed to succeed him. The position is somewhat similar to that of a trade union for any particular industry, as only one such trade union can be registered. Similarly, the British Chemical Trade Association has been recognized officially by the government authorities, and an interesting situation may therefore arise if it is decided to form a new body instead of going to amalgamation.

The appeal for funds of Manchester University has taken a form akin to a company prospectus, applications being invited for shares carrying no dividends, and it would seem that "conservative" Manchester is taking a leaf out of the American book as regards its method of publicity and giving a not unwelcome lead to others.

It is understood that Brunner-Mond are not acting alone in their purchase of the Billingham nitrate factory and the acquisition of a nitrogen monopoly, but that other heavy chemical interests such as Explosives Trades, British Cellulose, etc., are concerned.

Research Work Encouraged

Colonel A. W. Crossley, who did valuable work during the war at the poison gas experimental station near Salisbury, has left his professorship at King's College to take up the position of director of the British Cotton Industry Research Association of Manchester and about $1,000,000 is to be spent upon a research institute under his guidance.

Of more than passing interest is the transfer of the director of the British Photographic Research Association to one of the largest chemical firms, the change it is understood, having been made on condition that a transfer fee was paid to the funds of the Association. This arrangement seems to be without precedent—always a fetish in British national life—and, together with the incipient absorption of academic men in industry owing to its superior financial attractions, may be regarded as a sign of the times.

A Comparative Test Upon High-Speed Steels—I

Notes on a Competition of Modern High-Speed Steels Conducted for an Automotive Manufacturer—Preliminary Observations on Current Sales Practices and a General Review of Various Classes, and the Effect of Chemical Compositions and Heat Treatment

By A. J. LANGHAMMER, M.E.*

IN THE last sixteen years the use of high-speed steel has grown from practically a metallurgical and manufacturing experiment to what is today one of our most important economic and industrial factors. The principal reason for its wide application is the rapid growth of quantity production methods as applied particularly to the automobile, machine tool and allied industries, and the introduction of scientific management in these works.

Today there are dozens of brands of American-made high-speed steel on the market, and in the last eight months some of the famous English brands have again made their appearance. British-American brands too are very much in evidence, particularly in the crucible mills. Both electric-furnace and crucible steels are well represented, though the latter is still very much in preponderance.

Salesmen's Methods

High-speed steel selling methods of today leave very much to be desired. In general, the steel is sold by voluble salesmen who know nothing of their wares, have never been in a steel mill, and have never graced the floor of a machine shop. Fortunately, there are always some saving exceptions. It is indeed astonishing how little the average steel salesman knows of his product. If an interview is granted him, he begins by nonchalantly announcing that his brand is the best in the market, and that he can increase your production anywhere from 50 to 100 per cent, or more. When pressed for supporting data, he refers you to a local machine shop or some large manufacturer out of the city. During the war, Government plants and arsenals were quoted elaborately as using solely their steel. If you took the trouble to investigate, it would invariably develop that the particular brand in question had never been used, or that a small sample had been left gratis by the salesman for test purposes. Usually the test disclosed a mediocre or even a poor steel. The damage done to the steel company by such misrepresentation is almost immeasurable, for though it may later improve its product or even bring forth a superior brand, you still retain that bad taste from the interview and are suspicious, if not antagonistic.

Sometimes you meet in steel salesmen a canny old-time mechanic who has forced his way into the selling business and who is wiliness personified. If such a man is permitted to have a hand in directing the test, and the man in charge of the test is not himself an expert, then the result is never in doubt. The steel that the "old-timer" represents will win out.

High-speed steel salesmen often have access to a supply of specially-prepared steel for test purposes. At the mills a heat may be prepared which has the best possible composition and subsequent workings and heat treatments are very carefully performed. When this practice is not followed, a batch of "regular run" steel that has shown exceptional performance under test is retained for test purposes only. Obviously, when the steel company begins to fill orders, it will ship from the regular run of stock, which is inferior in quality to the "special" bar submitted for test purposes. In justice to the steel manufacturers it must be said that such practices seldom or never reflect the true policy of the companies represented (or misrepresented).

Most steel companies, too, manufacture several grades of high-speed steel. One of the grades is usually superior to all of the others and is the best steel that experience and careful manufacture can produce. This steel is then used for test purposes and should it win a place when the final selection is made, great care must be exercised to see that the "best grade" is received on subsequent shipments and not specimens of the poorer grades.

High Cost of Cheap Tool Steel

Much is found wanting in the average buyer or specifier. In most plants the purchasing agent decides on the brands, and he is naturally gullible on this subject. His decision is usually based on price, which to him is all important, while in reality it constitutes practically a negligible item. Then, too, if market conditions seem to warrant, as they do in recurring stress periods, he will buy as much high-speed steel as he can and of every available brand. In this way his errors are multiplied, for not only does he get steel which is primarily poor, but also such rejected stock as has been accumulated by the steel salesmen.

Under modern manufacturing conditions it is of utmost importance to know the comparative capabilities of the various brands of high-speed steel on the market. This applies to the small machine shop as well as the giant works. As stated above, the first cost of the raw material in a high-speed tool is practically negligible. This is true because the labor cost for the machining of such a tool is usually several times that of the raw material. Also, when a tool is made up of an inferior grade of steel, it may be scrapped after an attempt at hardening before it ever gets into the shop, thus producing an immediate combined loss of indirect material, labor and overhead. If the tool should successfully pass through the hardening room and subsequent inspection into the machine shop, trouble at once begins. Production is decreased, more work is incurred for the machine operator and tool grinder due to the increased tool changes, and costs increase accordingly. Spoilage or scrap also takes a jump and the costs increase again.

When the capabilities of certain brands of high-speed

*Industrial engineer, Thompson & Black, engineers and accountants, New York and Detroit.
Formerly mechanical engineer, Packard Motor Car Co.

steel are to be determined, it is imperative that the test be conducted under the constant supervision of a competent observer. This man need not be a technical graduate, but he should be a good mechanic and in addition he must possess the mental and moral qualities that permit him to follow instructions explicitly. The man in charge of the test, however, must be familiar with all the variables that affect the life of a cutting tool. He can then correctly plan the complete details of the test which will be executed by his subordinates. Too much stress cannot be laid on the fact that the man in charge of the test must know all the variables that are factors in the life of a cutting tool. One of the reasons that large quantities of relatively poor high-speed steel are used annually is that such tests are conducted by incompetent men.

In addition to the objection to the use of a large number of miscellaneous brands of high-speed steel noted two or three paragraphs back, there is that of difficulty in heat treatment. A standard method of heat treatment is all-essential for uniformly good results. Mediocre or poor grades of steel do not in general permit high heats and must be treated accordingly. If the next tool is made of a good steel which must be subjected to a high heat for best results, the chances are very much against its proper hardening, and the result is confusion, increased difficulties, more work, and finally a general run of poor tools. When quantity production methods are employed, as for example in a cutter or twist drill plant, these bad conditions are considerably augmented.

With a selection of brands that permit a uniform heat treatment, the tool hardener has an ideal condition and his work will show results.

Tool Steels in General

Carbon Steels

Carbon tool steel, which was the earliest form of cutting steel used in machine shops by manufacturers, is now used only in relatively small quantities for its once popular purposes except in cutting non-ferrous metals and non-metallic materials. It has a wide and universal application, however, for hand tools such as chisels, punches, dies, shearing blades, cutlery, broaches, hand taps and reamers, etc. Large quantities of plain carbon steels are also used for forging dies, hammer dies and machinery parts, though in these instances elements that promote toughening, resistance to wear and shrinkage are usually added to the alloy. As a cutting tool it fails because of the low duty that can only be exacted and the premature dulling of the cutting edges.

Self-Hardening Steels

Mushet, or self-hardening, tool steel (so called from the name of its inventor) was the immediate successor of carbon tool steel. This steel usually contained from 6 to 9 per cent of tungsten, 2 per cent of manganese, and a high percentage (about 2) of carbon. With the introduction of mushet steel, cutting speeds were increased about 60 per cent, and this record stands out as one of the most notable achievements of that time, though not fully exploited. Today this steel is obsolete, but it was of extreme usefulness in that it formed an indispensable link in the development of modern high-speed tool steel. It is an obsolescent product because practice today demands a cutting speed far in excess of its capabilities.

High-Speed Steel

Self-hardening tool steel was the immediate predecessor of high-speed tool steel. The composition of the average high-speed tool steel (by actual analysis of sixteen different brands) is as follows: carbon, 0.60 to 0.70 per cent; tungsten, 16 to 18 per cent (although one or two brands go as high as 22 per cent); vanadium, 0.75 to 1.05 per cent; chromium, 3 to 4 per cent. In addition to these "standard" elements, some brands contain also uranium, cobalt, manganese and molybdenum. Sulphur and phosphorus average from 0.02 to 0.04 per cent and the same minimum amount of silicon is generally present.

High-speed steel enabled an increase of about 400 per cent in cutting speed over mushet or self-hardening steel. The feature wherein the tools made from this steel differ from and exceed in performance the tools from the preceding steels is their ability to maintain a sharp, strong cutting edge while heated to a temperature far above that which would cause "failure" or "breaking down" of the cutting edges on tools made of the simple steels. As a matter of fact, the sharp cutting edge is maintained until just a short time before failure occurs. Carbon steel tools, on the other hand, show wear or dullness of the cutting edge as soon as they are put to work. The heat generated by the friction of the chips on the tool when cutting steel, plus the pressure, is great enough to weld small bits of the chip to the tool at some distance (depending principally on the depth of cut) back of the cutting edge proper and to wear a groove into the lip surface. The property of being able to retain hardness and cutting ability at a red heat is termed "red hardness." In the early days, the principal objection to high-speed steel was the apparent inability to produce a good finish. This handicap was largely imaginary and not well founded, for in the general run of work no such difficulty is experienced.

Stellite

As self-hardening tool steel was supplanted by high-speed tool steel, so the latter will in some cases give way to stellite when this alloy is applicable. Stellite is made up of approximately 65 per cent cobalt, 25 per cent chromium and 10 per cent molybdenum. It is extremely hard, quite brittle and possesses the quality of red hardness to a very marked degree. On cast iron, stellite has a cutting speed of 100 per cent above high-speed steel, while on bronze it may run as high as 700 per cent faster. On soft steel, honors are about even, depending on conditions. Stellite, however, is not adaptable even to cast iron or bronze when the tool is subjected to sudden shocks, on account of its brittleness.

Much work is being done in developing both stellite and similar alloys, but to date none of the rival products tested by the writer have equalled stellite in performance or adaptability. The range of utility of stellite is greatly increased, due to the fact that small rectangular or square sections can be readily welded in an electrical welder to large steel shanks, which arrangement gives a high-duty tool of low cost. The same procedure, of course, is applicable to high-speed steel.

Cast Tool Steels

Within the last two years several very promising brands of "cast high-speed steel," both air- and oil-

hardening, have been produced in this country. In some cases the alloy has a composition very similar to that of a good brand of high-speed steel, while in others no tungsten is used. Distinct advantages are claimed which greatly reduce factory costs. Thus it can be cast readily into almost any intricate shape such as dies for presses, milling cutters, core drills, form cutters and other special high-duty working and cutting tools. These castings, which usually anneal readily and machine easily, require but a small percentage of machining as compared with the tool made from a solid bar, whereby the labor cost is reduced very appreciably.

When placed in actual operation, some of these tools have produced as high as ten and twenty times as many parts as a regular high-speed tool on the same task, with the consequent saving in costs. Milling cutters made of such cast high-speed steel have been seen by the writer in use, and their performance appeared to be excellent. In this case, however, the duty was not very heavy, though the cutting speed was high, so that too much importance could not be attached to the one demonstration. Cutters of such material and of intricate design were at once ordered by the author's firm, but to date they have not been tested. In view of the recorded successes of "cast" steel and the large amount of experimental work that is being done with them, developments of extreme importance can be expected in the near future. This is the more interesting because the idea of casting high-speed steel is diametrically opposed to one of the fundamental requisites of a good high-speed steel, which is that the ingots must be of sufficient size that the proper reduction in area occurs in the working with the subsequent refined structure and hardy constitution.

English Brands

English steel makers are doing a great deal of work on high-speed steel, supposedly in an effort to produce a superior grade. As their efforts are chiefly confined to securing a substitute for tungsten, their object is probably to produce a cheaper steel. Molybdenum (already exploited by American metallurgists and discarded) is understood to be the principal element that is receiving their attention. Cobalt, too, is being thoroughly investigated, although both these elements are at the present time more expensive than tungsten. One English manufacturer has actually brought out a so-called "tungsten-less" high-speed steel that is being offered at an unusually attractive figure. In an actual cutting test, when run against a good brand of high-speed steel, it proved a failure. There may be quite a market for such a product, however, where a cheap cutting steel is desired for limited performance, or even for general work on aluminum, brass, or such easily machined metals. Again, this steel may be vastly improved, thereby increasing its usefulness.

Influence of Chemical Composition

It has been the writer's experience that the analysis of a particular brand of tool steel is but an indicator as to its ultimate capabilities. By this is meant that just because a high-speed steel has 18 per cent tungsten and other elements in proportion, it cannot be classed as a good steel on this basis alone. If, on the other hand, the analysis shows the presence of but 10 to 12 per cent tungsten, and no other substituting element, then one can readily assume that it would be a waste of time and money to investigate further such a steel. Since, broadly speaking, analysis does not in any way guarantee the performance of a tool, it is a grave mistake to order or purchase high-speed steel on the basis of specified composition only, which unfortunately is practiced by some large manufacturing industries. During an efficiency test, one of which is later described, it was always our policy to impress carefully upon the steel men that to us, chemical analysis as such meant nothing except as an indicator; the final requisite was that subsequent shipments of high-speed steel duplicated or closely approximated the performance of the test specimen. This usually served a good purpose, for not only would the salesman instruct the mill to inspect rigidly the first large shipment that was sent, but he would emphasize this point from time to time, because he knew that the steel would be subjected to a "check" test and the performance would have to be good.

The qualities ascribed to the various elements contained in high-speed steel are as follows, it being understood when discussing one that the other requisite elements are present in proper proportion:

Tungsten

Tungsten has long been credited as being the most valuable element in high-speed steel. The principal characteristic is that with a moderately rapid rate of cooling from high temperatures tungsten steels are exceptionally hard, and this hardness is retained even when the steel is again heated to a high temperature, because it offers a strong obstruction to the various changes from austenite to pearlite. This element, too, is very heavy, its specific gravity being about 19.3, it apparently diffuses very slowly, and in addition it is the most infusible element in steel with the exception of carbon. It is these three factors that may cause considerable trouble, especially in the crucible process, if in charging the tungsten is not placed at the top of the mixture so as to counteract in a measure its tendency to settle. If this tendency were not counteracted, an ingot of irregular composition would result. Tungsten raises the strength of the steel and also the temperature of fusion.

Vanadium

The effect of vanadium is to increase the hardness or red-hardness of cutting tools and also the resistance to wear. It has a strong affinity for oxygen and therefore probably acts to good advantage as a purifier. Vanadium greatly increases the strength of steel up to a certain percentage, though this limit is usually exceeded considerably in high-speed steel to get the effect of red-hardness.

Chromium

The effect of chromium in high-speed steel is to increase the hardness or red-hardness and also the life of the cutting edge. It also adds strength and especially toughness, thereby increasing the ability of the tool to withstand shocks and sudden strains. European steels, due presumably to their relative cheapness, use as high as 10 per cent of chromium.

Molybdenum

The use of molybdenum as a major constituent has in general been discontinued. High-speed steel with a goodly proportion of molybdenum is generally characterized by irregular performance, which is said to be due

to the ease with which it is volatilized. Such tools too often exhibit a tendency to crack in quenching. In general, molybdenum possesses the same quality of producing red-hardness as tungsten, though in a greater magnitude—possibly two or three times as great. This advantage is apparently lost almost entirely by reason of its instability, especially after re-hardening. However, European makers are now advocating the use of a relatively high percentage of molybdenum as a substitute for tungsten.

Uranium

To uranium is generally attributed the quality of increasing the red-hardness, ability to withstand shock and resistance to wear. It is also a powerful agent for removing gases, principally oxygen, nitrogen and their compounds. This element, however, apparently exhibits characteristics which call for careful mixing and expert handling at the steel mill. It appears, too, that the electric furnace is most adaptable for the manufacture of this steel.

Cobalt

To cobalt is usually attributed the quality of being able to cut extremely hard steel. It is generally conceded that an excess of cobalt produces a premature deadening or softening of the cutting edge. American manufacturers are apparently using little or no cobalt at present, probably due somewhat to its high cost.

Manganese

The effect of manganese in high-speed steel is to strengthen or toughen the body, at the same time allowing it to be worked readily. Apparently the effective range is very close, and when this is exceeded, excessive breakage results. It is believed that chromium is in general substituted for manganese.

TABLE I. MAKER'S RECOMMENDATIONS FOR TREATING LATHE AND PLANER TOOLS

Brands	Pre-Heating Temperature, Deg. F.	Hardening Temperature, Deg. F.	Quenching Medium	Drawing Temperature, Deg. F.
1	1600–1650	2250–2300	Oil until black, then cool in air.....	800–1000
2	No mention	Heat nose until it sweats, then quench quickly.....	No mention.....	No mention
3	No mention	About 2300	Cool in air blast until nose is cold.....	No mention
4	Bright red..	2250	Tempering oil.....	1000–1100
5	1700.....	2300.....	Lard-linseed or fish oil	400–600
6	1500–1700..	2150–2400.	Oil or air blast.....	No mention
7	No mention	About 2200	Air blast or oil.....	Draw when necessary
8	Red heat....	2200–2250.	Air blast or oil.....	500-600; 100–1100 for toughness
9	1400.....	2200–2300.	Air blast or thin oil.....	700 750
10	Red heat....	About 2300	Air blast or oil.....	No mention
11	1400	2200–2300.	Thin oil or air blast...	700–750
12	1375–1450..	2250.....	Oil or air blast.....	500–750
13	1400.....	2300.....	Oil.....	1065
14	1500.....	2200–2300.	Cottonseed oil.....	No mention
15	1400–1500..	2250–2300.	Oil or lead.....	1050
16	1400.....	2200–2250.	Oil or air blast.....	No mention
17	1450–1550..	2150–2250.	Oil or lead.....	When necessary
18	No mention.	About 2300	Fish or tempering oil..	650 1130
19	Cherry red..	White heat	Oil.....	No mention
20	Bright red..	Melting or running point....	Air blast.....	No mention
21	1750–1850..	2250–2300.	No mention.....	No mention
22	Cherry red..	White sweating heat.....	Oil.....	No mention
23	About 1400	2200–2300.	Air blast or thin oil...	700–750 in lead
24	No mention.	Slowly to 2100	Air blast.....	No mention
25	No mention.	2300 ..	Air blast or oil.....	None required

Carbon

Carbon is the element which forms the basis for all steel hardening and is a requisite constituent. In high-speed steel it is usually present in smaller amounts than would produce satisfactory results in the hardening of simple steels. This element in high-speed steel acts in a somewhat different way from what it does in the simple steels. In high-speed steel some of the carbon unites with the tungsten and chromium to form carbides of these two elements. The carbides in high-speed steel, especially tungsten carbide, are more insoluble than the cementite of the carbon steels and therefore, for hardening, a much higher temperature must be resorted to. The effect of carbon in connection with the various elements discussed above is beyond the scope of this work and will therefore be omitted.[1]

Inconsistency of Recommended Heat Treatments

The uncertainty of heat treatments recommended by steel makers is responsible for a great amount of cutting tool troubles and very much more accurate data should be forthcoming at an early date. This is especially true of the better steels. Precise information as to the proper time-temperature factor required for forging, pre-heating, heating and hardening, and drawing, at least, should be given. Variations for tools of different duties should be provided. Quenching mediums, "drawing mediums" and the time required for these operations should be given careful consideration.

To illustrate this point, the specifications of about twenty leading makers of steel (the majority of whom were represented in the test to be described later) are listed in Table I, and attention is invited to the apparent uncertainty in a large number of directions. For the sake of simplicity only the pre-heating, hardening and drawing temperatures plus the quenching mediums specified for "lathe and plane." tools are given.

(Part II will be published in our next issue.)

[1] For more detailed information concerning the influence of the various chemical elements in high-speed steel, the reader is referred to the works of Messrs. Arnold, E. T. Edwards, Carpenter, C. A. Edwards, Read, etc., in the *Journal* of the Iron and Steel Institute.

Automatic Gas-Analysis Apparatus for Government Helium Plants

S. F. Pickering, one of the members of the Bureau of Standards gas chemistry section, is to install additional automatic gas-analysis equipment which has been designed by the Bureau of Standards gas laboratories for use in the Government helium plants located in Petrolia, Tex.

The new equipment will record automatically the composition of the gas at twelve points in the plant, giving a written record every six minutes by equipment operating upon the principle of the differences in heat conductivity of the gases. At different points the relative amount of gas from two fields of the supply station, the relative percentages of methane and ethane, the relative percentages of methane and nitrogen, and relative percentages of nitrogen and helium, will be recorded.

This is the second and by far the larger installation which has been developed by this organization for the Government helium plants under the direction of E. R. Weaver, chief of the gas laboratories, Bureau of Standards.

FIG. 1. GOVERNMENT CASTOR OIL PLANT, GAINESVILLE, FLA.

Operation of the Gainesville Castor Oil Plant

A Description With Many Details of the Expeller and Solvent Extraction Process of Obtaining a High Recovery of Oil From Castor Beans—Cleaning and Tempering Beans—Drying and Bleaching Oil—Cake Extraction and Operating Difficulties

BY J. H. SHRADER* AND A. C. GOETZ†

WHEN the War Department decided that castor oil was absolutely essential for the lubrication of a certain class of airplane motors (rotary, air-cooled motors, notably the Gnome engine), it was found that the Government would have to secure about 5,000,000 gal. of castor oil. Even the industrial demands were in excess of this supply, on account of the difficulty of importing the beans. Hence, to assure to the army an ample supply of oil, it was necessary to arrange for a corresponding supply of beans. Since the heretofore greatest producer and exporter of this commodity was India, and since also the British Government needed a large supply of oil, the American officials not only sought far and wide for beans, but also contracted extensively through the Southern states for home grown beans. To crush this crop, save hauling at a time of great railroad congestion, and at the same time leave the meal and hulls in the localities where they could be utilized readily, the Government decided to erect a mill in the castor bean belt. At Gainesville, Fla., a large turpentine extraction plant, temporarily shut down on account of conditions attendant on the war, was leased. With this as a nucleus, the oil-expressing mill, warehouses and tanks were soon added. This equipment was purchased outright and held as Government property. Thus the expressing mill and equipment was owned by the Government, but the extraction plant was leased under a contract to return it to its owners. The whole plant was operated by the Gillett Oil Co., which was under contract to crush the crop and produce oil of specified quality. The Government was to pay for the cost of operation and allow the company a fixed rate according to the tonnage of the crush.

The plant consisted of a large seed storehouse, an expeller and refining room, an extraction house, a pomace storage house, together with sheds, tanks and engine room. A panoramic view of the plant is presented in Fig. 1.

CRUSHING THE BEANS

The procedure in castor bean crushing may be briefly outlined as follows: After weighing and cleaning, the beans are conducted to the heaters. These raise the temperature of the beans to about 100 deg. F. and discharge them direct into the expellers. These machines are continuous in operation and press out the oil and meal in uninterrupted separate streams. The oil is conducted to tanks, weighed and refined. The meal is conveyed to the extraction house, where it is placed in large retorts and treated with benzol to extract out the residual oil. The two grades of oil thus produced, namely, the No. 1 oil by expelling, and the so-called No. 3 oil by extraction, are tanked and constitute the ordinary commercial grades.

The Gainesville plant was designed to crush 100 tons of beans per day of 24 hr., and it was fully capable of handling this tonnage if the crops had produced. Their failure resulted in a tonnage of only about one-fourth of the beans required for capacity running. As an experiment and demonstration the mill was run to capacity several times by accumulating ahead enough beans for the runs. The railroad sidings could accommodate sixty cars. There were the usual track scales and scale house.

After the cars of beans were weighed on the track scale, they were moved to the seed storage house, the flat building to the right in the picture. This was a frame building 150 x 300 ft., with cement floor holding 300,000 bushels, calculating 2 cu.ft. per bushel, with brick fire walls dividing it into three parts. The beans were unloaded from the cars and placed on trucks, ten bags to the truck. An occasional bag or truck load was weighed by another scale provided in the bean storage house; if this weight was found to check with the re-

*Cocoanut Products Corp. Formerly Chemical Technologist, U. S. Dept. Agriculture.
†Formerly First Lieutenant in charge of Inspection of Chemical Supplies and Materials, Air Service.

ported weight on the bag, the weight of the car was accepted as reported. If the weight of one bag or truck did not check with the reported weight, then the entire lot of bags was weighed in the bean storage house. The beans were then trucked in by hand, but a stacking machine was used for piling. This machine was made by the Brown Portable Conveyor Machinery Co., Chicago.

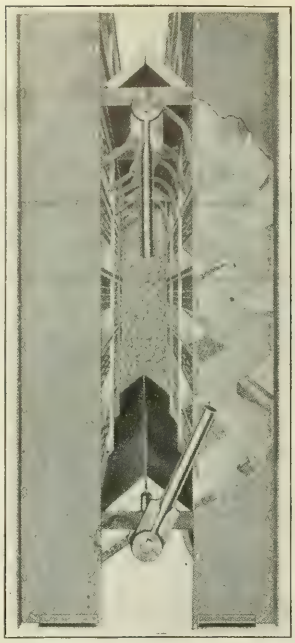

FIG. 2. HESS HEATER

Cleaning the Beans

Just below the surface of the floor in the middle of each half of the house were two belt conveyors each 300 ft. long covered with removable traps. Through wooden portable spouts, each holding the contents of a bag and large enough to set over a trap and deliver its charge clean, the beans were dumped onto the two conveyors and carried to an elevator, which raised them to a storage bin over the cleaner. The beans then dropped to a No. 4 Invincible Bean Cleaner, which had a capacity of handling 150 tons daily. This machine is made by the Invincible Grain Cleaning Co., Silver Creek, N. Y.

After passing through the cleaning machine, the beans were elevated to a storage bin, whence they passed to an Automatic Richardson Scale dumping 350 lb. at a charge. This scale is manufactured by the Richardson Scale Co., Passaic, N. J.

Tempering the Beans

From the scales the beans passed by a belt conveyor to a bucket elevator, which raised them to the heater. This heater was manufactured by the Hess Warming & Ventilating Co., Chicago, Ill., and had a capacity of approximately 150 tons per 24 hr. The Hess heater, Fig. 2, consisted of a galvanized iron hopper under which were columns of trays with pitched bottoms. The beans flowed downward by a zigzag course into another hopper, from which they discharged automatically through chutes to the expellers. The purpose of the heater was to raise the temperature of the beans in order to expedite the expression of the oil. The Hess heater was so arranged that in addition to the heating coils, there were open steam pipes. If the beans were found to be too dry, the moisture content and the temperature of the beans could be quickly increased by opening the live steam pipes, thus increasing the humidity of the heating room.

The heater was enclosed in a concrete room over the expeller room. (See Fig. 3.) The temperature of this room should be kept at 180 deg. F. In the construction of the chutes for the beans from the Hess heater, care was taken that the angle of slope was not less than 45 deg., to insure ready flow. In shutting down, the lower hopper of the Hess heater was left entirely empty so as to prevent the passage of cold beans from the heater when starting up again.

The expeller room, Fig. 4, was equipped with fifteen No. 1 Anderson expellers made by the V. D. Anderson Co., Cleveland, Ohio. The optimum temperature for the beans on entering the expellers was 120 deg. F. Good practice showed the temperature of the oil just as expelled to be about 80 deg. C. (176 deg. F.). The cake was about 120 deg. F. Actual tests of the temperature of the oil from the expeller taken just beneath the barrel as the oil was expelled were as follows:

	Temperature of Oil, December, 1919	Temperature of Oil, January 13, 1919
	79	74
	77	78
	79	84
	79½	87
	87	..
Average,	80	80¾

The cake was about $\frac{7}{16}$ in. thick and ran 12 to 13 per cent oil and about 6 per cent moisture. The capacity of an expeller was 800 to 900 lb. of beans per hour with a 13 per cent cake.

A small jet of steam was allowed to play into the stream of beans in the chute just immediately before they entered the expellers.

Screens were placed under the barrels of the expellers to remove surplus foots or meal. In the earlier runs, the amount of meal per 24 hr. per expeller was probably not over four quarts, but this increased as the machines operated longer until it required auxiliary equipment to handle it. This was not provided; the result was a curtailment of capacity due to loss of oil in the meal. All such meal, when it became excessive, was sent to the extraction house, yielding its oil as No. 3 grade. From the expeller the oil was conducted by closed screw conveyors to a sump tank. The cake was delivered by screw conveyors to the extraction house, where it was loaded directly into the retort or stored on the charging floor. The operation of the extractors will be discussed later.

FIG. 3. EXPELLER HOUSE

The sump tank had a capacity of 750 gal. It was cleaned from two to three times a week, the foots from the cleaning being placed in the No. 3 mixing tank. From the sump tank the oil was pumped to the weighing tank, which had a capacity of 32,000 lb., or about 6-hr. run at full capacity. The oil was carefully screened before passing into the weighing tank to remove any particles of seed coats or hulls which might later give trouble in the bleaching of the oil. It was found that the presence of such particles materially darkened the oil in the heating prior to bleaching.

Vacuum Pans

From the weighing tank the oil was pumped to the vacuum pan, 8 ft. diameter x 15 ft. depth over all, with a 4-in. vacuum pipe, made by the F. J. Stokes Machine

Co., Philadelphia, Pa. This pan had a capacity of 30,000 lb. of oil, but it was usually operated with 26,000 to 28,000 lb. Six to eight hours were required to dry the oil in the vacuum pan at a temperature of 230 deg. F., using 28 in. of vacuum. One of the three mixing tanks or bleaching tanks was also fitted up as a vacuum tank and could be used as such when necessary.

In order to secure the best possible agitation and to secure a thorough dehydration, the oil was pumped out from the bottom and into the top of the tank and thus circulated in one complete cycle two or three times within the period that the oil was being dehydrated.

Bleaching

The oil in batches of about 18,000 lb. then passed from the vacuum pan to the mixing or bleaching tanks, of which there were three—two for No. 1 oil and one for No. 3 oil. If the mixing tanks were all in use, the oil could be passed to the storage tank. In the mixing tanks the oil was agitated and brought to a temperature of 210 deg. F., held there for a short time and then dropped to 190 deg. F., when 2 per cent Florida fullers earth and 0.85 per cent decolorizing carbon bought from Salomon Bros., New York City, were added. When the temperature of the tank was over 190 deg. F. it was always under a vacuum. The oil in the bleaching tanks was circulated when the fullers earth and carbon were added and during the whole period of bleaching.

After agitation the oil was passed through the usual type of plate and frame filter presses containing thirty-six 30 x 30 plates. Each plate was covered by a sheet of Bachman filter paper and one duck cloth, the oil passing first through the paper and then through the duck. The filter paper for the plates enabled the cloths on the first press to be used for three batches of oil, whereas when the paper was not used the cloths had to be changed for each batch.

After passing through the first press, the oil was run back to the mixing tank until it flowed clear, whereupon it was pumped through the second press, which was of the same description as the first press, but provided with one cloth and two papers. The pressure on the first press varied from 50 to 125 lb. per sq.in., the maximum pressure on the second press being about 40 lb. The finished oil passed from the second filter press to a small preliminary storage tank, thence to the large storage tank.

There were in all four filter presses. One filter press

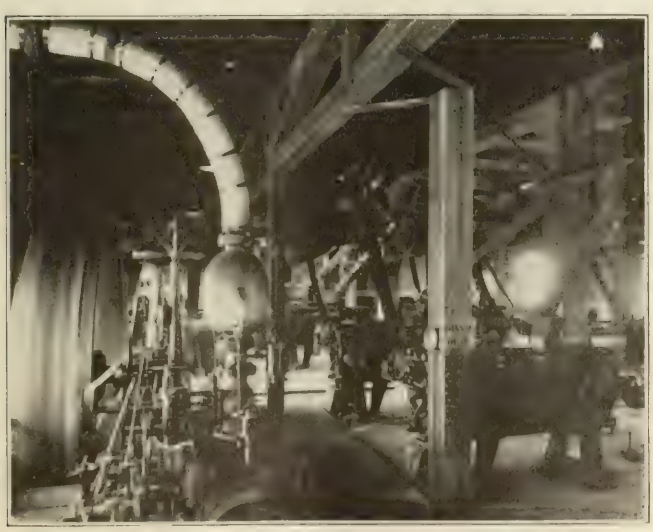

FIG. 4. EXPELLER ROOM

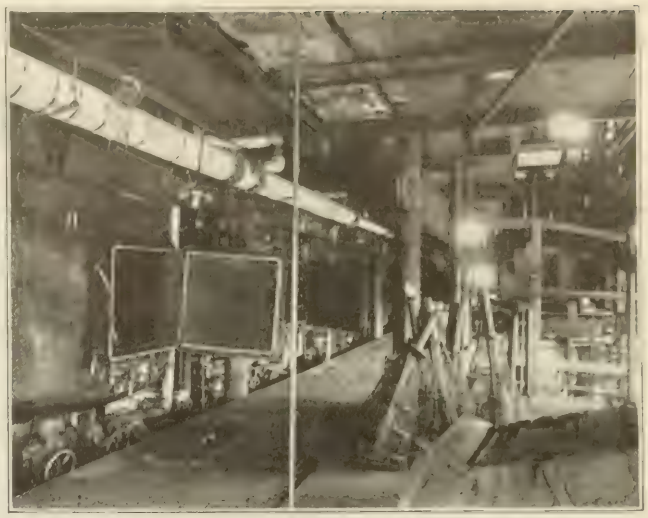

FIG. 5. RETORT BUILDING

was used for filtering No. 3 oil exclusively. Under ordinary conditions when the filter presses worked well, a 2,200-gal. batch of oil could be filtered in about 3 hr. Compressed air was blown through the filter presses after filtering to remove as much of the oil as possible. The filter cloths were cleaned by first soaking and washing in caustic soda water, then rinsing in hot water, wringing and drying. The residues from the cloths were sent to the extraction house to recover the last traces of oil.

In pumping the oil in the refinery, there were used two 2½-in. belt-driven rotary oil pumps, standard No. 6, each equipped with a 2½-in. suction and a 2½-in. discharge, manufactured by the Gould Manufacturing Co., Seneca Falls, N. Y. These pumps gave entire satisfaction.

The capacity for storing No. 1 oil consisted of one 250,000-gal. tank and three 30,000-gal. tanks. In addition there were two 5,200-gal. filling tanks and one 30,000-gal. storage tank for No. 3 oil.

Extraction Plant

Difficulties Experienced. The extraction plant was formerly used by the Florida Industrial Corporation for extracting pine tree stumps for turpentine, rosin, etc., and was erected by the Ernest Scott Co., Fall River, Mass. (Fig. 5.) The extraction apparatus worked very well for the extraction of the above products, but was unsatisfactory without remodelling for the extraction of the castor pomace. The principal changes in the plant were in piping and the addition of a system for agitating the charge and breaking up channelling.

There were eight extractors, each 9 ft. in diameter x 12 ft. tall, arranged in groups of four. It was estimated that the extractors would hold 3,000 lb. of pomace to the vertical foot. Considerable difficulty was experienced at first in operating the extraction plant, largely because stirrers or sweeps were readily broken from the shaft during the process of agitation. At first they were placed so as to clear the floor of the extractor; they were then raised to about 2 ft. above the floor and provided above and below with teeth 2 ft. long and 6 in. apart. This arrangement, however, did not work satisfactorily, for the sweeps still broke. Another difficulty experienced was in drying the castor pomace after extraction, due to it packing so tightly during extraction and steaming off of solvent that the moisture could not

be removed. Instead of loading 10 tons in one charge into the extractor, only 2½ to 5 tons could be loaded. If the pomace was not dried to within a moisture content of 12 to 13 per cent or, better, 10 per cent, it decomposed with a loss of ammonia, resulting in a consequent decrease in the value of the pomace.

At the top a manhole admitted the pomace during charging; on the side near the bottom, a large door permitted the removal of the charge. An agitator of the single-arm, sweep type rotated on the vertical axis of the retort. The floors were constructed with false bottoms supported on girders. These bottoms consisted of first a circular iron plate (in sections) about ½ in. thick and perforated with ½-in. holes. Over this was placed another plate about ⅛ in. thick with ⅛-in. holes. This second plate worked very well for chips, but did not work for castor pomace. There was substituted for this upper plate a covering made by burlap over ¼-in. mesh chicken wire. Over this burlap was spread a layer of castor bean hulls about 6 in. deep. Much time and effort were devoted to this problem before a satisfactory solution was found.

Overcoming Packing of the Charge

In order to effect the removal of the last trace of the solvent and in order to dry the pomace, it was necessary to pass live superheated steam through it. Considerable difficulty was experienced in pumping the solvent and driving off the last traces of moisture and solvent on account of the persistent packing of the charge. It was found necessary to change the practice of pumping the solvent in at the top and down through the pomace to the bottom by reversing it, pumping in at the bottom and forcing the solvent upward. The height of the solvent in the extractor was regulated by an adjustable arm in the extractor added by the Gillett Oil Co. It was found that pumping from the bottom to the top gave very good results and overcame the difficulty due to the formation of an impervious layer. However, packing of the charge was still troublesome. This manifested itself by difficulty in drying the pomace; even the aid of a vacuum did not solve the problem. After trying many methods, the following was finally adopted in January, 1919, and found to give satisfactory results:

Placed proportionately around the inside of the extractors and near the walls were nine upright 1-in. capped pipes perforated with ⅛-in. holes about every 8 to 10 in. The height of these pipes was regulated by the depth of the charge. After extracting the oil from the pomace, it was found that if steam was blown through it by means of these upright pipes, the pomace could be made dry enough not to decompose. This method was tried out in one extractor and found to give such excellent results that the remaining extractors were adapted to this method of drying. Under this arrangement the extractors could be worked to handle ten tons of material to be extracted per charge, extracting to about 1 per cent of remaining oil. From loading to loading about 20 hr. was required, but this time was often reduced to about 15 hr. Even at 20 hr. per extraction the extractors could handle the expeller cake from a 100-ton daily expeller run.

Operation of the Extractor

The castor pomace was charged in at the top of the extractor and all openings on the extractors tightly sealed. Solvent was then pumped through the mass a sufficient number of times to extract all the oil economically. The first and usually the second washings were pumped direct to the storage tank, which led to the purifiers (solvent stills). The third and fourth washings were used for the first and second washings on the next extractor in the same unit. Sometimes heat was used when the solvent was to be pumped through the extractor and sometimes not, depending upon conditions. After the solvent had been pumped off from the extractor, the heat was applied by a closed coil to distill off the solvent.

The last traces of solvent were driven off by means of live steam blown through the mass of pomace in the retort. During the "blowing off" with steam, a vacuum of about 10 in. was used. This vacuum assisted greatly in driving off the last traces of solvent vapor and moisture. These were pumped to the separating tank, which consisted of one large tank with a partition almost dividing the tank in two, the moisture and solvent entering one side of the tank. The water settled to the bottom and the solvent overflowed the partition to the other side. The vents from this tank and the vacuum pumps were sealed by a barrel of oil. This oil absorbed the last traces of solvent, later recovered in a third purifier.

Purification of No. 3 Oil

After reaching the storage tank (about 5 ft. in diameter and 20 ft. long), the solvent and oil were conducted by gravity to the purifiers, made by Ernest Scott, Fall River, Mass. In the purifiers most of the solvent was driven off by steam, leaving the No. 3 oil behind, while the condensed solvent was pumped to the separating tanks. The oil was then conducted to a tank, where it was treated with live steam to remove all traces of solvent and to clarify the oil. The exhaust from this tank was also conducted to the separators. The No. 3 oil was then pumped to the mixing tank in the refinery, where it was treated with fullers earth in the proportion of 250 lb. of fullers earth to 2,200 gal. of oil, merely for clarifying purposes. The oil was then passed through a filter press to the storage tank. The capacity for storing No. 3 oil was one tank of 33,000-gal. capacity.

Extraction Operation Reports

An idea of the time and procedure in operating the extractors can best be obtained by study of the accompanying retort reports, Tables I and II:

Pomace House

From the extractors the pomace was dumped directly onto a conveyor and sent to the pomace house, a peaked building about 100 x 50 ft. and 50 ft. high, divided into two parts. The pomace passed from the conveyor to a No. 8 Bauer Bros. grinding mill, and thence by an elevator to a conveyor traveling the length of the house just under the roof. From this it was dumped in any part of the house desired. Mechanical conveyors loaded the pomace directly into cars.

The power plant consisted of one 200-hp. water tube boiler operating at 150-lb. pressure, and two return tubular boilers of the Casey-Hedges make, Memphis, Tenn., 200 hp. operating at 150-lb. pressure, giving a total of 400 hp. Wood was used as fuel on account of the plentiful supply and the scarcity of coal, but the latter was later used. Superheated steam was used throughout the plant. In the expeller room there was a Hamilton Corliss engine, 250-hp. girder frame type. In the powerhouse furnishing the electric power was a 260-hp. condensing Ames Uniflow engine directly connected with a 180-kw. generator.

There were also two 7¾-in. barrel type well pumps made by the Keystone Drill Co., Beaver Falls, Pa. These pumps gave more than an ample supply of water for boiler and fire purposes from two wells on the premises. There were also two sets of fountain sprays, for cooling the extractor and condenser.

Laboratory

The mill was equipped with a chemical laboratory to control all factory operations. This consisted of examining all incoming beans and finished pomace for moisture and oil. Such tests as bleaching, oil in expeller meal, and other matters of routine character, were carried out from time to time. Determination of the acidity of the finished oil was always necessary, as this and color were the only specifications under the control of the manufacturing procedure.

Capacity and Yields

At a time that all the fifteen expellers were operating they crushed in 8 hr. 82,800 lb. of beans, yielding 40,260 lb. of oil (about 5,000 gal.) with its attendant moisture. Another test run was as follows: 41,400 lb. of beans produced 15,962 lb. of oil (38.05 per cent). From Nov. 8, 1918, the date the plant commenced operation, to Dec. 31, 1918, there was produced 257,456 lb. (32,182 gal.) of No. 1 oil. To produce this, 715,000 lb. or 15,540 bushels, of beans were crushed. This corresponds to 36 per cent of No. 1 oil, or 15.56 lb. of oil to a 46-lb. bushel. The production of No. 3 castor oil was 4,300 gal., with about 2,000 gal. still in process of manufacture.

Analytical Data

Table III gives the analyses of the oil produced at this plant.

TABLE III. ANALYSIS OF CASTOR OIL RECEIVED FROM THE GILLETT OIL CO.

G. A. Kirchmaier, Chemist, Toledo, Ohio

No. 3500-A.

	Specification Tests	No. I	4th Run II	Batch 6 III	Batch 7 IV	Batch 8 V
5	Specific gravity, 15 deg.	0.962	0.961	0.961	0.9612	0.9611
4	Color	Yellowish	Same	Same	Same	Same
6	Solubility	Soluble	Same	Same	Same	Same
7	Acidity, acid number	1.7	2.91	2.1	2.4	2.3
9	Iodine number	85.1%	80.8%	83.7%	85.4%	86.1%
10	Saponification number	179	180	180	178	182
12	Unsaponifiable number	0.3%	0.21%	0.28%	0.26%	0.3%
13	Rosin	Negative	Same	Same	Same	Same
14	Cottonseed oil	Negative	Same	Same	Same	Same
16	Viscosity (Engler)	2019	2020	2020	2018	2019
17	Flash point	526° F.	525° F.	525° F.	526° F.	527° F.
18	Cold test (Zero F.)	O. K.	O. K.	O. K.	O. K.	O. K.

All of the above samples comply with U. S. specification, the oil is good, a trifling yellowish cast or color, could be removed with bone black and clay to satisfy requirement in drug trade, but not necessary for mechanical use.

The beans crushed were almost entirely the first crop of those raised in this country from imported seed. The analyses extend over the whole period of operation from November, 1918, to June, 1919, inclusive.

BEANS	Per Cent	POMACE	Per Cent
Moisture	5.31	Moisture	13.04
Oil	45.15	Oil	2.40
Highest value	57.50	Lowest value	0.20
Lowest value	38.00	Highest	25.95

These values are not selected, but include all batches, notably those produced early in the operation before the extractors were made to perform satisfactorily. The average for the last few weeks of the operation was: Oil, 1.03 per cent; moisture, 10.13 per cent.

Oil No. 1		Oil No. 3	
Specific gravity	0.9620	Specific gravity	0.9614
Acidity, per cent	0.98	Acidity, per cent	4.80

A sample of hulls analyzed:

	Per Cent		Per Cent
Moisture	10.35	NH_3	1.27
Oil	1.88	K_2O	1.99

A sample of pomace analyzed:

	No. 1 Per Cent	No. 2 Per Cent
Moisture	15.05	11.28
NH_3	4.49	5.81
K_2O	0.89	0.99

Quality of Products

No. 1 oil: The No. 1 produced when operations first began had a higher color and higher acid (about 1.25 to 1.50 per cent) than the usual c.p. castor oil of commerce. The acidity of No. 1 oil later on ran about 1 per cent acid. The color of this oil was as light as most of the No. 1 oil produced by the regular trade, but was slightly muddy or dull or not quite so snappy in appearance as some No. 1 oil. The slightly dull appearance was not noticeable to the layman and could be noticed only when compared directly beside the very best No. 1 oil of the regular trade.

The production of No. 1 oil improved in quality steadily, and earlier poor batches were better as regards color and acidity than some No. 1 oil old process previously produced and now produced by the old established firms.

No. 3 oil: The No. 3 oil at first was very dark in

color, but improved very markedly until that later produced was equally as good as the regular No. 3 oil on the market.

Pomace: Due to the high moisture content of the pomace caused by the earlier poor operation of the extractors, the pomace produced at first heated and decomposed. With the later methods of operating the extractors, a low or normal moisture content was secured. The pomace also was uniform in fineness, which was a quality not possessed by some of the old-established brands.

General Statement

The Government castor oil mill was the first castor oil mill, expeller process, on a large scale ever erected. Some years ago castor oil was made by this method with success, but no large mills were ever erected using exclusively this process. Heretofore the old-type hydraulic process was used. Really the only difficulty experienced at the Government castor oil mill was in the operation of the extractors. These difficulties have been previously described. At the time of closing down, the plant was doing all and more than it was expected to do. It produced a castor oil which conformed to the specifications of the Air Service and further conformed to the U. S. Pharmacopœia castor oil. The production of the plant was earlier limited by the capacity of the extractors, but these were so improved that the mill met the original expectation, which was a capacity of 100 tons per day of 24 hr.

If the war had continued, the production of castor oil at this mill for airplane lubrication would not have been retarded. The capacity of the expellers could be pushed to 150 tons per day. Under stress of war times, no doubt, the extractors could have been put in satisfactory operation sooner. As it was, however, they were finally working successfully and producing a satisfactory pomace, extracting the pomace down to 1 per cent of oil, much better practice than obtained in some of the oldest and largest mills in this country.

Thus in about eight months the Government built and operated the largest castor oil mill in the world and produced high-grade oil from beans of local production, whereas the American castor bean crushing industry was built up on crushing beans mostly of East Indian variety. In the above short period this mill produced a grade of oil fully up to the specifications of the Air Service and ahead of expectations in a commercial sense. Objection has been made that the oil deposits a slight amount of foots on standing. Some of this oil does so react, but since ordinary commercially produced oil does likewise, it can hardly be charged with justice against the operation of the above plant. Another objection encountered was with respect to the excessive wear on the expellers. It was found, however, that they do not wear any more than with operating on peanuts. Excessive meal is discharged during long operating, but auxiliary equipment can handle this trouble. One of the best commentaries on a process is the attitude of the operators to it. In this case, they would unquestionably use expellers for crushing castor beans. With regard to the operation of the extractors, the staff made them applicable to extracting castor beans, one of the most difficult oil-seeds to handle due to the mushy, non-fibrous character of the kernel. Only the cessation of hostilities and partial failure of the home-grown bean crop prevented the mill from functioning fully up to its estimated capacity.

A Plea for the Scientific Study of Cellulose Chemistry

By Harold Hibbert

IN A previous communication on "The Future of Industrial Organic Chemistry"[1], it was pointed out by the writer that the study of aliphatic compounds has been subordinated both here and in Europe to that of the aromatic, and this in spite of the fact that the actual cash value of the latter is an insignificant sum in comparison with that of the former. Attention was directed to the value of the United States cotton crop for 1918, which according to the report of the Department of Commerce amounted to the huge sum of $1,616,207,000.

Importance of Cellulose Industry

If we consider the total amount involved in the production and utilization of cellulose in the manufacture of such products as textiles, paper pulp, vulcanized fiber, artificial silk, cellulose nitrate and acetate, viscose (artificial silk) and celluloid, the total amount involved is probably greater than in any other single industry, with the possible exception of steel and coal.

In view of the fact that by far the greater portion of the world's supply of cotton is grown in America and that all of the industries mentioned above are now established here on a firm footing, it is difficult to understand why the scientific study of the chemistry of this so fundamentally important raw material should have been almost entirely neglected. The results of such neglect are apparent in every field where the application of cellulose plays an important role, for all of these industries have been built up essentially on empirical data rather than based on deep-seated knowledge of the nature of the constitution of the cellulose molecule.

Few American Contributions to Chemistry of Cellulose

During a discussion on cellulose at a recent meeting of the New York Section of the American Chemical Society[2] it was pointed out by the writer that the scientific study of cellulose chemistry has been neglected to such an extent that it is not only necessary for the American student to study abroad (since few facilities are available in any American university or college), but that he has also to depend on foreign literature for the fundamental and scientific facts covering this field.

It may possibly be of interest to record the fact that a review of the contents of the *Journal* of the American Chemical Society for the period 1893-1918 shows that during this interval of twenty-five years only three papers were published under the heading of Cellulose or Cellulose derivatives. Of these three papers one represents a contribution from the Sheffield Scientific School, Yale University, in 1907 on the "Estimation of Cellulose in Wood," by Dean and Tower. The second is entitled "Notes on Cellulose Esters," by R. G. Woodbridge, and was published in 1909 as a contribution from the Massachusetts Institute of Technology, while the third is a paper on "New Solvents for Cellulose," by H. G. Deming, published in 1911 from the University of Wisconsin. It is of interest in this connection that the second research was carried out with funds provided by Dr. Arthur D. Little for the purpose of carrying out

[1] Chem. & Met. Eng., vol. 21, pp. 335-341 (1919). This article was reproduced in *Chemiker Zeitung*, vol. 43, pp. 573-576 (1919), under the title "Die Ueberschaetzung der aromatischen und Unterschaetzung der aliphatischen organischen Chemie."

[2] Chemists' Club, New York, Nov. 7, 1919.

"scientific" (as distinct from "technical") research. This total contribution of three short papers to the advancement of the science of cellulose chemistry from a nation claiming a chemical society with a membership of about 13,000 chemists and controlling the world's supply of the raw material is not, it must be admitted, one which the American Chemical Society as a body, or the chemical industry, can view with any great degree of complacence. The surprising feature is that the industries themselves should not have contributed anything, and this in spite of the enormous wealth accumulated by them. This point is even more accentuated by the fact that during the same period several thousand contributions have been made by the chemists of other nations. This is plainly seen if we analyze the authorship of important articles referred to, for example, in the well-known text book on Cellulose by Schwalbe. An investigation of the references quoted in the footnotes shows that the total number of such amounts to about 2,500, of which 23, or less than 1 per cent, refer to American authors

Publication of Scientific Data Urged

On the occasion of the sectional meeting referred to above an earnest appeal was made by the writer to the large industrial companies to take an interest in the subject and, by publishing their scientific (as distinct from their technical) results, to assist the universities, colleges and chemical students generally in obtaining a more accurate and comprehensive knowledge of the subject, since it is only through publication that the progress of the science can be secured.

The industry has hitherto adopted an altogether too parochial attitude on such matters, but with the new spirit now in evidence a much better outlook is in prospect. Thus tribute must be paid to the scientific contributions on tungsten and other metals as well as to remarkable theoretical papers from the laboratories of the General Electric Co.; to the fine spirit shown by the du Pont company in financing and publishing scientific data on nitroglycerine, and to the contributions by The Barrett Co. and other large concerns, while the admirable series of library synopses planned by the Arthur D. Little Co. represent a praiseworthy public-spirited contribution to chemical progress.

In view of what has already been said, it is not in the least surprising that the information necessary for the development of new cellulose industries such as that of artificial silk, etc., should have had to be procured abroad.

The researches of Abel, Cross and Bevan, Green, Knecht, Fenton, Vieille, Grandmougin, Vignon, Chardonnet, Girard, Nastjukoff, Georgievics, Saposhnikow, Witt, Baeyer, Schwalbe, Ost, Will, and many others are well known to chemists, both scientific and industrial, and only make the absence of American contributions the more conspicuous. While tribute is gladly paid to the valuable compilations of Worden on cellulose derivatives, there is still lacking a comprehensive *scientific* textbook in English on the subject, comparable for instance to the well known textbook of Schwalbe.

The subject of cellulose chemistry, on account of the colloidal nature of cellulose, is closely related to, and interwoven with, that of colloid chemistry, and the enthusiasm and interest awakened in this latter subject through the efforts of Bancroft and others might well be utilized for the purpose of increasing our scientific knowledge in this field.

If we consider such subjects as the question of the best type of cellulose suitable for the manufacture of photographic paper, writing paper, celluloid, nitrocellulose, etc., we find each industry subjecting the raw material to a special treatment founded on data which are in the last analysis entirely empirical and which must remain so until the research chemist is able to provide some more definite data regarding the chemical nature of the cellulose molecule. How can the active interest of the chemist in the subject be best awakened and stimulated? The answer would seem to be first of all by the publication of the scientific data already in possession of the industries, and secondly by the endowment of several university professorships for the encouragement of scientific research in this field, together with provision for a considerable number of research scholarships.

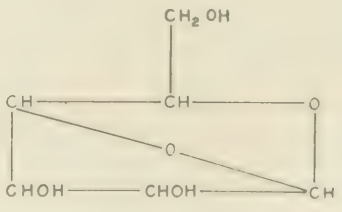
The country and the public generally are now both accustomed to the idea of special industries being concentrated in the hands of a limited number of companies, since it is only through the combined wealth associated with such organizations that sufficient funds are available to meet the large expense involved in carrying on more or less unproductive research for long periods of time. Granting this, they have at the same time the right to demand, in view of their benevolent attitude toward such trade combinations, that these latter shall repay such considerations by contributing their share to the progress of the science, progress which can be assisted in no better way, in the writer's opinion, than along the lines just indicated.

The time has long since passed when the country's knowledge of cellulose chemistry should be confined to the ranks of a few technical experts and it is to be hoped that the coming decennium will witness the publication in American journals of a vastly increased number of valuable scientific and technical communications on cellulose chemistry.

Constitution of the Cellulose Molecule

It must not be forgotten that the problem of the constitution of the cellulose molecule is one requiring the intimate co-operation of the botanist, the organic chemist and the physical chemist. Sooner or later America will presumably have its National Research Institute and the study of the chemistry of cellulose and wood products would seem to be one peculiarly adaptable to such an environment. In the meantime the universities, if liberally endowed and financed, can contribute much of value, as the forthcoming publication of the brilliant researches carried out recently at Yale by Prof. T. B. Johnson and his pupils on the constitution of silk will clearly demonstrate.

In connection with a forthcoming paper dealing with a new formula for cellulose proposed by the writer, namely,



it is hoped that opportunity may be found for a discussion of certain promising lines of scientific research in this field.

Electrochemical Industries in Sweden

By J. W. Beckman

A VERY extensive investigation on the utilization of water power for electrochemical purposes in Sweden has recently been published by Prof. Wilh. Palmaer, professor of chemistry at the Royal Technical University of Stockholm, and the growth of the industry, as indicated by him in this publication, is of such a kind that it should stimulate countries situated in a similar way to further efforts.

Sweden is a sparsely-settled territory which is about as long as the Pacific coast between the Mexican line and the Canadian line. Its total width is not over 300 miles, which naturally affects the transportation question very materially.

It has been customary all over the world to look to Sweden and Norway as pioneers in the electrochemical developments and this is primarily due to the fact that the people of Sweden have at an early date been impressed, through the means of the daily papers, of what hidden wealth was stored away in the flowing rivers of that country.

Prof. Palmaer's pamphlet covers the field completely up to 1918. When the Swedish production figures are compared with similar figures of the United States, they are pygmies, but in spite of that, Swedish electrochemical products are found all over the world.

Electrochemical Sodium and Potassium Salts Industries

The total power used in the manufacture of caustic soda and bleach products in Sweden up to 1918 was 2,140 kw., which was divided among four factories. The reason for the comparatively small production of these products is due to the fact that salt, essential as raw material in this industry, has to be imported from Germany or the southern countries of Europe. The cost of this material is therefore considerable and has held back the industry, though there is a large demand both for caustic and bleach. In all the paper mills bleach is needed badly, and large quantities of this material have been imported from as distant countries as the United States.

Potassium chlorate and perchlorate have been produced in considerable quantities and 750 kw. is consumed by this industry alone. The chlorate manufacture is one of the oldest electrochemical industries in Sweden and has an enviable position on this account.

Other Electrochemical Industries

The calcium carbide manufacture has been carried out with a total power consumption of 24,000 kw., with an increase during the war of about 25 per cent.

The fixation of atmospheric nitrogen has gone forward considerably, and the latest information indicated that 16,375 tons of cyanide was produced and 12,000 kw. was consumed in the synthetic manufacture of nitric acid.

The shortage of sulphuric acid in Sweden during the war and the demand for increased food-product yields stimulated the possibility of developing electrochemical phosphate processes for the production of a soluble phosphate suitable for fertilizing purposes. Prof. Palmaer has developed such a process, which has shown itself efficacious under special conditions.

At the present time there is being used 2,000 kw. for the manufacture of potash salt and potassium cyanide in electric furnaces. The process has proved itself successful, and should open the field for the synthetic manufacture of potassium cyanide in parts of the United States where potash silicates and cheap electric power are available.

There is being utilized at the present time 700 kw. in the manufacture of carborundum, and the manufacture of alundum has been under serious consideration. For the manufacture of artificial graphite 1,650 kw. is being utilized.

About 1,000 kw. is being utilized, in two different plants, in the manufacture of phosphorus. In addition to the industries mentioned above, a number of small plants taking close to 1,000 kw. are operating, producing hydrogen, oxygen, hydrogen peroxide and other products, which find a ready market in the country.

Electric Iron, Steel and Ferro-Alloys

The Swedish pig-iron industry is gradually being changed over to an electric pig-iron industry, and the impulses have been strong along these lines during the war years. The total power consumption for the manufacture of pig iron in electric furnaces up to 1918 was about 70,000 kw., an increase of three and a half times that in 1915.

Along with the electric smelting of pig iron the electric steel furnaces have grown and there are at present installed forty-two electric steel furnaces consuming 7,975 kw.

The ferro-alloys, such as ferromanganese, ferrochrome, ferrosilicon, silico-aluminum, manganese-silico-aluminum and manganese-copper, have grown parallel with the steel industries, and the total consumption for these industries amounts to approximately 45,000 kw.

Electrolytic Copper Refining

Other metallurgical processes have been contemplated, but the most interesting is the electrolytic refining of copper, a matter which is of great importance to Sweden, since the country's electrical industries are highly developed and the need for refined copper for these is very essential. Small amounts of copper are produced in the country, and these will be refined there. The war, of course, has indicated the danger of complete dependence on outside sources for refined copper.

Summary

The following table shows the growth of electrochemical industries in Sweden during the years 1904-1917:

Year	No. of Electrochemical Plants	No. of Kw. Consumed	Value of Products in Swedish Crowns*
1904	8	9,000	4,500,000
1908	10	13,500	7,500,000
1911	14	25,000	11,000,000
1913	22	60,000	20,000,000
1915	36	78,000	31,000,000
1917	75	126,000	55,000,000

* $1 = 3.75 crowns at normal exchange.

Photo-Sensitizing Dyes in Demand

Extensive commercial use is being made of the sensitizing dyes produced by the Bureau of Chemistry as a part of its war work. The recent successful development of color photography is resulting in a brisk demand for isocyanines, pinaverdol, pinacyanines, krytocyanines, and other sensitizing dyes. They were developed originally for aircraft photography.

Supply of Inorganic Nitrogen in the United States

The Inadequate Domestic Supply of Nitrogen in the United States Is Supplemented by Importations From Chile—Summary of Figures on Consumption and Supply Showing Deficiency Even if Government Plants Are Operated

By Major D. P. GAILLARD
Nitrate Division, Ordnance Department, U. S. A.

A PREVIOUS paper on the consumption of inorganic nitrogen in the United States outlined the conditions during the last twenty years and considered the factors that would probably affect our consumption of nitrogen in the future.* It is important to investigate the source of supply of nitrogen from which this demand can be met. The United States has been very largely dependent upon importation for its supply of nitrogen, as only a small part of the total nitrogen consumed has been produced here. This domestic production has come from the recovery of nitrogen contained in all bituminous coal in connection with coking for the manufacture of coal gas and byproduct coke. The principal source of imported nitrogen has been the nitrate fields of Chile. There have also been imports, comparatively small in amount, from Europe of byproduct nitrogen and from Canada of nitrogen fixed from the atmosphere. The supply of nitrogen, therefore, comes from imports and domestic production.

Nitrogen Recovered From Coal

Byproduct Coke Production

Byproduct coke ovens were first introduced in this country about 1893, but by 1902 the total coke production from this source was only 5 per cent of the total. There was a more or less constant growth to 1912, in which year about 25 per cent of the total coke was produced in byproduct ovens. The consequence of this very rapid increase was a tendency toward an oversupply of byproducts, and consequently the building of additional byproduct ovens was checked somewhat until stimulated by the war. Since 1914 the increase has been abnormal, owing to the demand for the byproducts in the manufacture of munitions. In 1917 and 1918, in order to secure an adequate supply of toluol, the basis of TNT, the Ordnance Department stimulated by special contracts the construction of many additional byproduct ovens. The last of the ovens so constructed will not be completed until about the middle of 1920. As the result of this increase, in 1918 about 46 per cent of the total coke was produced in byproduct ovens. In 1919 the demand for coke decreased very considerably, and while the production of byproduct coke fell off 4 per cent from the 1918 figures, the production of beehive coke fell off 44 per cent from figures for the previous year, as the consequence of which the proportion of byproduct coke produced in 1919 was 56 per cent.

The byproduct ovens now in existence, together with those contracted for during the war and now under construction and nearly completed, it is estimated can furnish a maximum coke production of 36,500,000 tons a year, or 64 per cent of the record high 1918 consumption; or 82 per cent of the 1919 consumption of coke, which although considerably lower than that in 1918, has previously been exceeded in only three years and equaled in one other year.

Beehive Coke Production

These figures without further study might confirm the popularly held idea that the beehive ovens in this country are being replaced by byproduct coke ovens, but this has not been the case. A study of the coke production statistics compiled by the U. S. Geological Survey shows that in the last fifteen years there has been no general decrease in the production of beehive coke. The average annual production of beehive coke during this 15-yr. period is approximately 29,900,000 tons. For the first five years of this period this production averaged 30,100,000 tons, for the next five years 30,400,000 tons, and for the next five years 29,300,000 tons; or, in other words, there has been a falling off in the last 5-yr. period over the first 5-yr. period of only 3 per cent. It is evident, then, that the byproduct coke ovens in the last fifteen years have been built to take care of the increase in the demands of the country for coke, but that, considering the country as a whole, there has been no substitution whatever as yet of byproduct ovens for beehive ovens.

Future Pig-Iron Production

To forecast intelligently the future demand for coke it is necessary, as has been stated before, to consider the probable growth in the pig-iron industry, a fundamental industry of the country and one reflecting so accurately the general business conditions that it is often used as a "barometer of industry." A study of the statistics of pig-iron production as reported by the U. S. Geological Survey shows a practically constant growth in the last twenty years, the annual increase averaging about 1¼ million gross tons per year. The industry has grown somewhat irregularly, periods of reduced production following every few years periods of record production; but the growth given above represents the average growth during this period. The production fell in 1914 because of the poor business conditions prevailing that year owing to the outbreak of the war. It recovered to approximately normal the next year, rose to a record high figure of 39,434,797 tons in 1916, declined very slightly in 1917 and again in 1918, being 38,230,440 tons in the latter year. With the cessation of war demands and the absorption of war stocks of iron, together with the hesitation of business while waiting for lower prices, as well as with the interruptions caused by steel and coal strikes, the production fell in 1919 to approximately 30,500,000 tons. If the normal growth of 1¼ million tons per year had continued to 1920, it is estimated the consumption last year would have been in the neighborhood of 36,000,000

*See Chem. & Met. Eng., vol. 22, No. 17, p. 783.

tons instead of 30,500,000 tons, as was actually the case.

During the war steel was to a very considerable extent cut off from non-essential industries, and a great amount of construction work was postponed. It is reasonable to assume that in the next few years the major part of these accumulated unfilled requirements must be met. Further, the growth in certain industries, such as the automobile and farm tractor industries, will require releatively increasing amounts of steel, and the substitution of steel for wood in bridges, buildings, and for various other uses will continue. Further, there is a possibility of some increase over our pre-war exports. On the other hand, it is unlikely that railroad requirements for steel—a very considerable part of the total requirements in past years—will be so great as previously. Furthermore, the production of pig iron in this country has doubled in the last fifteen years, increasing much faster than the population. In other words, the per capita consumption of steel and steel products has very materially increased in this period. It is evident that this increase cannot go on indefinitely, but opinions differ as to just how near the country is to the point of saturation.

In view of this it is believed that the most accurate estimate that can be made at this time is to assume that the production of pig iron in this country during the next few years will continue to increase at the average pre-war rate of 1¼ million tons per year. Under this assumption pig-iron production in 1924 would be in the neighborhood of 43,000,000 tons, which amount, it is interesting to note, is somewhat less than the present total pig-iron capacity of the country as recently estimated by one of the trade journals. Under this same assumption the production in 1930 would be 50,500,000 tons.

Future Byproduct Coke Production

The coke required to produce 43,000,000 tons of pig iron, together with the amount of coke used for other purposes, would be, based on past experience, approximately 63,000,000 net tons. The byproduct ovens now built and building can supply approximately 36,500,000 tons, or approximately 58 per cent of this—a greater proportion of byproduct coke than there has ever been in the past—leaving, if no new byproduct ovens are constructed, a total of 26,500,000 tons to be furnished by beehive ovens. It is pertinent to note that this is only 89 per cent of the average beehive production for the past fifteen years, and that the beehive production during these fifteen years has fallen below this figure in only three years.

It is entirely possible that sooner or later byproduct ovens will supply from two-thirds to three-quarters of the total coke production, but it is very unlikely that they will displace beehive ovens to any greater extent than this. The iron industry has always been a business of ups and downs, and consquently the coke requirements have fluctuated from year to year. A study of the statistics shows in the last fifteen years four cases in which the production of coke has fallen off very considerably from the previous year, the percentage of decrease ranging from 36 per cent to 15 per cent of the production of the previous year and averaging for these four years 25 per cent. A byproduct oven once built must continue in operation if possible, not only because it must carry much heavier fixed charges on capital invested than the cheaper beehive oven, but if shut down it must be partly reconstructed at considerable cost before placed in operation again. On the other hand, the simple beehive oven can be put into operation after an extensive period of idleness at comparatively small cost. Business considerations would therefore indicate that the maximum production to be expected from byproduct ovens would be that production necessary to supply the minimum requirements, the difference between the minimum requirements and the maximum requirements—that is, the non-continuous requirements—being taken care of by the cheaper and simpler beehive ovens. A study of the statistics of coke production from these two sources for the past few years shows very clearly how much less capable the byproduct production is of fluctuating with the variable demand. For instance, in 1908 the production of beehive coke fell off 38 per cent from the previous year's figure, while the production of byproduct coke decreased 22 per cent. In 1911 the production of beehive coke fell off 21 per cent, while the production of byproduct coke increased slightly. In 1914 the production of beehive coke fell off 33 per cent and byproduct only 12 per cent. In 1919 the beehive production fell off 44 per cent and the byproduct only 4 per cent.

Increase n Byproduct Ovens Improbable

It is very unlikely, however, that in the next five years there will be any considerable number of new byproduct ovens constructed. Not only is the cost of construction more than double the pre-war cost, but the production of byproducts from the coke ovens now built and building will be approximately three times that of the highest pre-war year. Under these conditions, with the extensive world-wide demand for capital, it is difficult to see how any considerable amount of money will be invested in the byproduct coke oven industry, abnormally stimulated during the war, in order to further increase, in a period of high costs, an already plentiful supply of most of the byproducts.

It is possible, however, there will be certain individual byproduct coke ovens constructed where local conditions may be peculiarly advantageous; but it is believed that an allowance for the year 1924 of a million and a half tons of coke from byproduct ovens other than those now built and building is a very liberal one.

We therefore have for 1924 a maximum possible production of 36,500,000 tons of coke from coke ovens now built and building, and an additional allowance of a million and a half tons of coke from ovens which may come into production during this period, making an estimated total byproduct coke production in 1924 of 38,000,000 tons, or 60 per cent of the total coke production. This would require the coking of approximately 53,500,000 tons of coal.

In 1930 to manufacture the estimated production of 50,500,000 tons of pig iron and to meet the other requirements there will be required approximately 73,500,000 tons of coke. It is estimated that byproduct ovens will supply approximately 50,000,000 tons, or 68 per cent of this, leaving 23,500,000 tons to be furnished by beehive ovens. These figures compare with 38,000,000 tons and 25,000,000 tons estimated from these two sources for 1924. In other words, it is assumed that not only will all the increase in coke requirements be furnished from byproduct ovens, but also that byproduct ovens will replace the beehive ovens operating in 1924 to the extent of 1,500,000 tons of coke.

The production of 50,000,000 tons of coke in beehive

ovens would require the coking of approximately 70,000,000 tons of coal.

Yield of Ammonia

Statistics collected by the U. S. Geological Survey prior to the war indicated for the byproduct coke ovens all over the country an average yield of 5 lb. of ammonia per ton of coal coked. During the war, owing to the use of inferior coals and the lower efficiencies during forced production, this yield decreased to slightly less that 4½ lb. It is believed, however, that pre-war conditions can be equaled again and therefore in these estimates an average recovery of 5 lb. of ammonia per ton of coal coked is assumed. It is believed that this figure is liberal, and while in certain cases the recovery may run as high as 6½ lb., in other cases it runs very materially less than 5 lb.

Total Ammonia From Byproduct Ovens

On the basis of 5 lb. of ammonia recovered per ton of coal, we would have an ammonia recovery for 1924 from the coking of 53,500,000 tons of coal in byproduct ovens, of 133,750 tons of ammonia, equivalent to 535,000 tons of ammonium sulphate, and in 1930 from the coking of 70,000,000 tons of coal, 175,000 tons of ammonia, equivalent to 700,000 tons of ammonium sulphate.

Ammonia Recovered in Manufacture of Coal Gas

In the manufacture of coal gas coal is coked in retorts differing somewhat from byproduct coke ovens, but methods of recovery are very much the same. Exact figures for the several past years in the production of ammonia from this source are not obtainable, but as only a relatively small proportion of the total ammonia recovered comes from gas works and this proportion is constantly growing less, a reasonable approximation will be sufficient for our purposes.

In 1915 the U. S. Geological Survey reported a total production from gas works of 12,980 tons of ammonia, and in 1917 of 11,440 tons. These are the only two recent years on which exact statistics are available, but estimates of production during the last eight years show an annual production varying from a minimum of somewhat over 10,000 tons to a maximum of 13,000 tons. The high year was 1915, since when the production has apparently decreased slightly. It is believed that an allowance for 1924 of 15,000 tons of ammonia and in 1930 of 18,750 tons of ammonia from gas works will be ample in view of the experience in the last few years. Further it is believed that the extremely small amount of ammonia from bone carbonizing works can be included in these figures without error.

Total Ammonia Recovered From Coal

We thus have for 1924 as the maximum amount of ammonia that can reasonably be expected to be recovered from coal, 133,750 tons from byproduct coke ovens, and 15,000 tons from coal gas and bone carbonizing works, or a total of 148,750 tons, equivalent to 595,000 tons of sulphate of ammonia, or 122,500 tons of nitrogen. In 1930 we would have 175,000 tons of ammonia from byproduct coke ovens, and 18,750 tons of ammonia from gas works, or a total of 193,750 tons of ammonia, equivalent to 775,000 tons of sulphate of ammonia, or 159,500 tons of nitrogen.

The Fixation of Atmospheric Nitrogen

Commercial Plants

In the past there has been almost no quantity fixation of atmospheric nitrogen within the limits of the United States. For a few years a small arc process plant operated in North Carolina and more recently another small arc process plant has been operating in the state of Washington. Some other experimental and development installations operated on a very small scale, but the aggregate supply from all these sources has been a negligible factor in the country's total supply of nitrogen.

Government Plants

During the war, U. S. Nitrate Plant No. 1, at Sheffield, Ala., using the General Chemical Co.'s modification of the Haber process, and U. S. Nitrate Plant No. 2, at Muscle Shoals, Ala., using the cyanamide process, were practically completed.

Experimental operation had started at Plant No. 1, but the process is not yet developed and considerable further study of the fundamentals of the process and modification of the equipment are necessary before regular production can be secured from this plant.

Plant No. 2 was tested and showed conclusively that it could produce fixed nitrogen at its rated capacity—approximately 45,000 tons per year—at reasonable cost. Altogether No. 2 plant produced about 600 tons of nitrogen in 1918 and about 700 tons of nitrogen in 1919. The production from No. 1 plant was negligible.

Future Production From Government Plants

If Congress authorizes the operation of the two plants for the production of nitrogenous materials to be used in the manufacture of fertilizer as recommended by the War Department, it is estimated that the production from this source will be approximately 45,000 tons of nitrogen in 1924, gradually increasing to 55,000 tons of nitrogen in 1930.

Future Production From Privately Owned Plants

Within the last few months the General Chemical Co. and the Semet-Solvay Co. have joined forces for the further development of the Haber process in this country. It is most unlikely that there will be any considerable tonnage production from this source by 1924, as it is doubtful if the process will be developed on a manufacturing basis much before that time. If this process is worked out, which is still much of a question, it will gradually enter as a production factor and in order to be liberal it is assumed that by 1930 about 25,000 tons of nitrogen may be secured from this source. To secure this production will necessitate the investment of not far from $20,000,000, and it is not believed that this industry will develop any faster than this.

Nitrogen From Imports

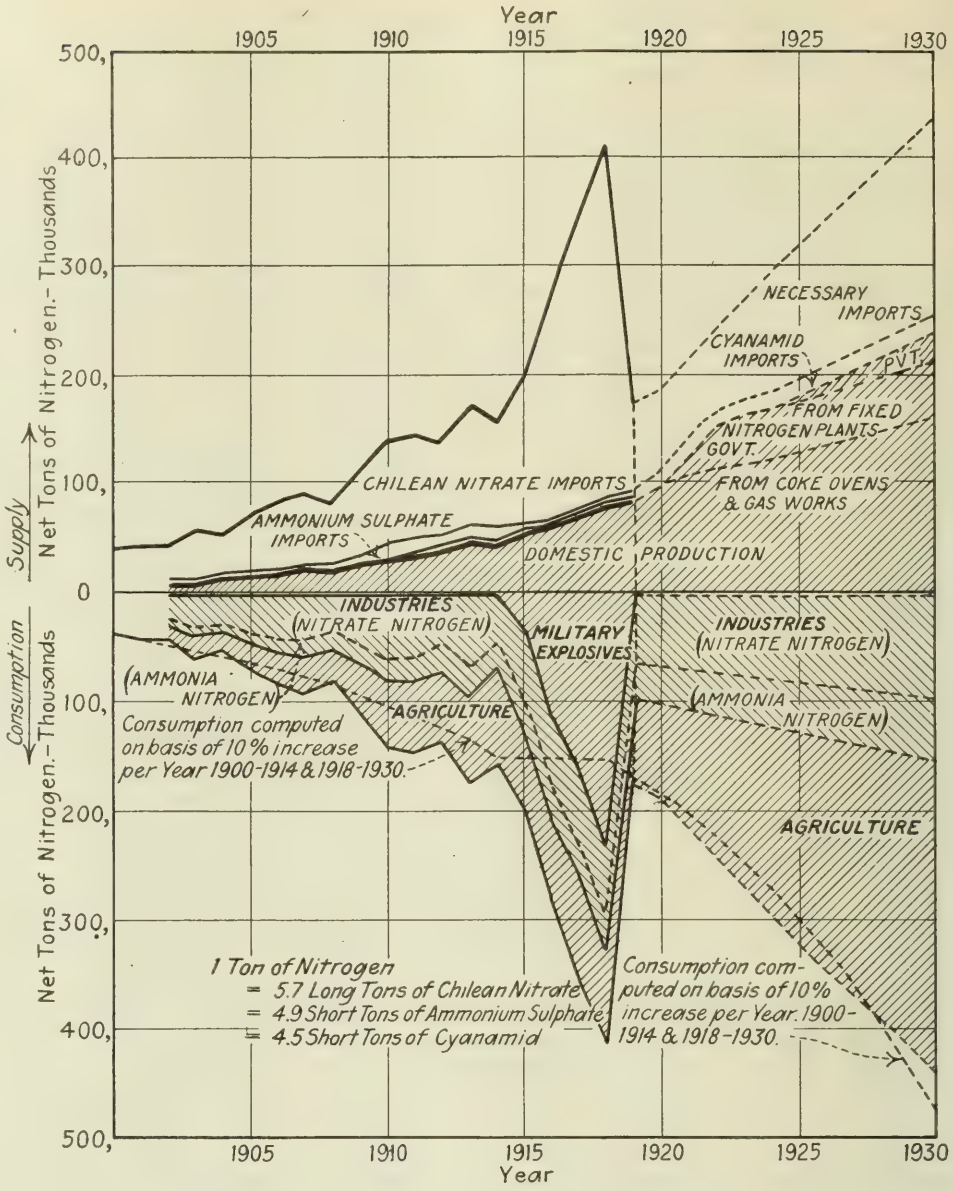
Past Imports

In the past twenty years more than three-quarters of the nitrogen consumed in this country has been imported, principally from Chile in the form of nitrate of soda, usually known as Chilean nitrate.

For a few years before the World War considerable amounts of sulphate of ammonia were imported, for the most part from England, furnishing at a maximum somewhat less than one-fifth of the total nitrogen im-

ported; but during the war England needed this nitrogen at home and imports from this source fell to almost nothing. The plant of the American Cyanamid Co. at Niagara Falls, Canada, for the fixation of atmospheric nitrogen entered into production in 1910 and imports of cyanamide from this plant have steadily increased since that date, but they furnished only a very small fraction of the total nitrogen imported. The main reliance of this country, however, in the past has been the importation of Chilean nitrate and the abnormal war demands were met almost entirely by expansion of this source of supply.

A study of the nitrogen situation indicates that the requirements of the country will in the future as in the past first absorb the domestic production. This will be the case as domestic nitrogen can always undersell any imported nitrogen. It is evident that this is true with the nitrogen from the byproduct coke ovens and gas works, where the cost of production, as is the case with any byproduct, is largely a matter of bookkeeping. This is also true in the case of the Government nitrate plants, which can fix and sell nitrogen at an operating expense less than any probable selling price of imported nitrogen in the next ten or twenty years. The nitrogen which it has been estimated will be produced in the future from privately owned fixed-nitrogen plants will certainly not materialize unless private capital is convinced that nitrogen from this source can undersell, if necessary, any imported nitrogen. In other words, under the conditions that will prevail in the future, when the consumption will be considerably greater than the domestic supply, the price will be controlled by the cost of the imported nitrogen necessary to supply the deficiency in the domestic production, and the imports will therefore just be sufficient to meet whatever deficiency there may be.



ACTUAL AND ESTIMATED SUPPLY AND CONSUMPTION OF NITROGEN IN THE U. S., 1900 TO 1930

Whether most of this imported nitrogen will be in the form of Chilean nitrate or whether some nitrogen may be obtained either from the European byproduct coke ovens or from European fixation plants is immaterial. It is believed, however, that most of it, over and above the relatively small amount contained in the cyanamide imported from Canada, will be furnished by Chilean nitrate, as has been the case in the past.

The imports of nitrogen, other than those of Canadian cyanamide, which it is estimated will furnish 15,000 tons of nitrogen, necessary to supply the estimated deficiency of domestic production in 1924 amount to 112,000 tons of nitrogen, equivalent to approximately 640,000 long tons of Chilean nitrate, and in 1930 to 183,500 tons of nitrogen, or slightly more than 1,000,000 long tons of Chilean nitrate.

Summary

The preceding consideration of the probable consumption in 1924 and 1930 of inorganic nitrogen for agricultural, industrial and military purposes, and the supply to be expected in these same two years from the coking of coal and the fixation of nitrogen within this country and the importation of sufficient nitrogen to meet the deficiency in domestic production, may be summarized as shown in the table.

In order that this forecast of future conditions may be readily compared with the actual conditions prevailing in the past, and in order that the trend of increase may be better studied, the accompanying chart has been prepared.

This chart shows the actual supply and consumption

of inorganic nitrogen for each year since 1900 and the estimated supply and consumption for each year to 1930.

It will be noted by a comparison of the bottom line on the chart showing total consumption with the dotted curve immediately above it that the total use of nitrogen in this country increased at a rate somewhat greater than 10 per cent each year from 1900 to 1914. The tremendous demand for nitrogen for military explosives during the World War materially checked this growth in the peace-time uses of nitrogen from 1914 to 1919. It will be noted, however, that the future consumption of nitrogen is estimated to continue at practically this same rate of growth, at least for the next ten years, and it is believed that the preceding discussion shows that this assumption is conservative.

SUMMARY OF ESTIMATED SUPPLY AND CONSUMPTION OF INORGANIC NITROGEN

Estimated Peace Time Consumption in	1924 Tons of Nitrogen	1930 Tons of Nitrogen
Agriculture	172,000	285,000
Industries	120,000	150,000
Military explosives, assumed	2,500	3,000
Total consumption	294,500	438,000
Estimated Domestic Supply from		
Coking of coal	122,500	159,500
Privately owned fixed nitrogen plants	.....	25,000
Total domestic supply	122,500	184,500
Deficiency in domestic supply if Government plants do not operate	172,000	253,500
Estimated Supply From		
Government fixed nitrogen plants	45,000	55,000
Deficiency in domestic supply if Government plants operate	127,000	198,500
Estimated Imports Necessary		
Canadian cyanamide	15,000	15,000
Chilean or European nitrates, if Government plants do not operate	157,000	238,500
If Government plants operated	112,000	183,500
Proportion of Total Consumption Furnished by Domestic Supply	Per Cent	Per Cent
If Government plants not operated	41.6	42.2
If Government plants operated	56.9	54.7

NOTE—Nitrogen exported from the United States is not included in the above, as amount of future exports is uncertain, and if included only makes the deficiency of domestic supply more marked.

It will also be noted on this chart how the war demand, considerably greater than the entire consumption in this country of inorganic nitrogen for all purposes in any year prior to the war, necessitated importing from Chile in 1918 almost three times as much nitrogen as had ever been imported before, and it shows graphically how greatly dependent this country was during the war on this importation.

The chart shows further how the expansion of nitrogen supply from coke ovens and gas works, even though abnormally stimulated by the war demand, will not furnish in the future half of the nitrogen used in this country, and unless this source of supply is supplemented as soon as possible by the operation of the Government fixed-nitrogen plants, and further supplemented by such development of the private fixed-nitrogen industry that there may be, this country will be even more dependent on imported nitrogen ten years from now than it is at present, and not only will the country be less well prepared from a military point of view but the American consumers, which include directly a very large proportion of the farmers of this country as well as many of the most fundamental chemical industries, and indirectly the greater part of the population, will find it harder than ever to get an adequate supply of nitrogen at a cost within reason.

Influence of Slag and Nitrogen on the Corrosion of Iron

AT THE Boston meeting of the American Electrochemical Society, April 16, 1920, L. T. Richardson presented a paper on "The Influence of Enclosed Slag on the Corrosion of Wrought Iron," in which he noted the controversy between makers of pure steel and genuine wrought iron as to the relative merits of the two materials for resisting corrosion. Referring to Hadfield's, Rosenbain's, and Braune's work on ancient irons, he comes to the conclusion that "those ancient iron objects which have shown such a remarkable resistance to corrosion are made of puddled iron, and it is therefore only natural to expect that iron manufacturers of today in their search for a corrosion-resisting material should attribute the rust-resisting qualities of these old irons to just those properties that characterize wrought iron itself. These distinguishing properties are two in number—a chemical one that the iron is quite pure, and a physical one that the iron has long layers or threads of slag or cinder scattered throughout its mass. Some even go so far as to say that each fiber is coated with an almost infinitesimal film of slag. It almost follows that because of these two different characteristics, the resistance of wrought iron to corrosion should be ascribed to two different causes by two classes of observers—one claiming that the resistance of wrought iron to corrosion is due mainly to its chemical purity; the other contending that it is due to its physical structure.

"The very structure of wrought iron offers a means of testing, to a certain extent, these two theories.

"It is easily seen that in one direction, namely, perpendicular to the slag layers, the metal is not contin-

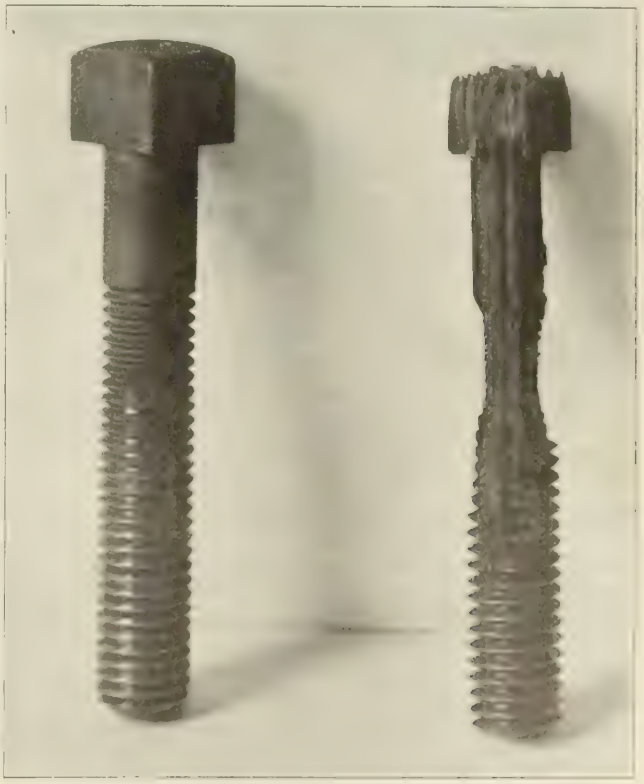


FIG. 1.

At left, open-hearth iron with no slag inclusions; at right, puddled iron with slag dissolved out.

uous and any oxidation of the metal as it penetrates inwardly from the surface must meet layers of slag. In the other direction, however, that is, in a direction parallel to the layers of slag, the metal is continuous and as it penetrates will not meet these layers of slag or cinder. Hence, if corrosion is retarded by slag inclusions, one would expect to find that transverse sections of wrought iron will rust more rapidly than longitudinal sections.

"In order to test out this line of reasoning, transverse and longitudinal sections about $\frac{1}{16}$ inch in thickness were taken from pieces of Swedish iron and wrought iron and subjected to rusting at different times. The pieces were thoroughly annealed and the surfaces made smooth with emery cloth. After weighing and measuring the thickness of each piece in several places, all were placed in a wooden rack, and exposed to the weather.

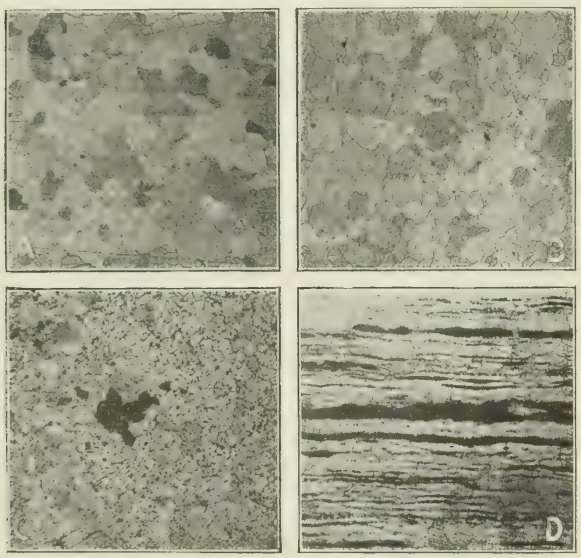

FIG. 2.

A—Transverse section, pure open-hearth iron. × 60.
B—Longitudinal section, pure open-hearth iron. × 60.
C—Transverse section, puddled iron. × 60.
D—Longitudinal section, puddled iron. × 60.

"The analysis of the different irons, the exposure data and the results are as follows:

	Sulphur	Phosphorus	Carbon	Manganese	Silicon	Copper
Steel	0.032	0.079	0.08	0.56	.....	None
Wrought iron (A)	0.044	0.132	0.015	0.095	0.193	None
Wrought iron (B)	0.020	0.100	0.020	0.038	0.180	None
Swedish iron	0.015	0.052	0.015	0.011	0.050	None
Wrought iron (C)	0.026	0.115	0.04	0.05	0.210	0.10

	Time Exposed	Transverse Section Loss in Weight	Transverse Section Depth Pits	Longitudinal Section Loss in Weight	Longitudinal Section Depth Pits
Steel	.....	.....	.....	.....	.....
Wrought iron (A)	6 mos.	0.1178	0.035	0.1101	0.033
Wrought iron (B)	6 mos.	0.0791	0.044	0.0789	0.041
Swedish iron	6 mos.	0.1068	0.026	0.1333	0.026
Wrought iron (C)	2 years	0.153	0.020	0.154	0.025

The loss in weight is in grams per square centimeter and was obtained by cleaning the rusted specimens with a solution of ammonium citrate. The depth of pits was obtained by grinding the surface of the cleaned specimens until the pits on the surface were removed.

"In view of the fact that the corrosion of transverse and longitudinal sections is the same as regards loss in weight and depth of pits, the conclusion has been reached that any superior resistance to corrosion that wrought iron may have is not due to slag inclusions but to some other causes, among which may be mentioned the purity of the iron."

The statement that ancient irons were of a nature and manufacture similar to puddled irons was contradicted by J. A. Aupperle, of the American Rolling Mill Co. He pointed out that prior to 1784, when Henry Cort invented the puddling process, all iron had been manufactured by the direct process, i.e., the ores had been smelted with the use of charcoal. After Henry Cort's invention of the puddling process, wrought iron was produced by this method, which gradually superseded the charcoal iron process. In the puddling process the iron ore is first reduced in a blast furnace, then cast in pigs which are remelted in the puddling furnace. Such iron, therefore, is produced by the indirect process, quite dissimilar to the earlier methods.

However, the speaker was in accord with Mr. Richardson's conclusion that purity in iron is essential to long life, quoting analyses of some rust-resisting irons.

"In our research work we have studied the gas content of iron and steel and the influence of gases upon the rate of corrosion. In the examples cited the nitrogen content will be found extremely low. In fact, I have never analyzed an ancient iron without finding low nitrogen. This is undoubtedly due to the method of manufacture. It is my opinion that the nitrogen content exerts a greater influence upon the rate of corrosion than any other element.

"In contrast with durable irons we have numerous examples of steel which failed in a very short time. All of those which failed in a short time were found to be high in nitrogen. We have had 26-gage bessemer sheets, which were exposed to the weather, fail within thirteen months; other sheets of the same gage lasted thirty-four months.

"In the following table will be found the analysis of a pipe and also a spike, which in addition to containing high nitrogen also contain a high percentage of carbon monoxide. I have also included the analysis of pure iron made in an open-hearth furnace for the purpose of showing that the nitrogen content in the above failures is ten times as high as the nitrogen content of pure iron. This comparison also shows that the carbon monoxide is several times higher in the pipe and spikes which failed than the pure iron.

	Failure of Pipe in Alkali Soil After 14 Mos.	Failure of Spike in Railroad Ties Arizona, After 9 Yrs.	Pure Iron Made in an Open-Hearth Furnace
Carbon	0.090	0.100	0.010
Manganese	0.357	0.405	0.025
Phosphorus	0.098	0.108	0.004
Sulphur	0.049	0.041	0.025
Silicon	trace	trace	trace
Copper	0.014	trace	0.040
Nitrogen	0.041	0.033	0.004
Oxygen	0.032	0.082	0.015
Carbon monoxide	0.052	0.058	0.015

"Based upon the data which we have accumulated, we find the gaseous impurities have a greater influence upon the rate of corrosion than the solid impurities.

"I have been able to dissolve the slag from a sample of puddled iron as shown in Fig. 1. Both the puddled iron and the iron made in an open-hearth furnace were submerged for half their length for 2 hr. in 25 per cent sulphuric acid. The pure iron bolt was attacked but slightly. The slag in the puddled iron bolt had dissolved to such an extent as to indicate the fibrous nature of the product. This test seems to confirm what Mr. Richardson has said about the slag offering no protection from a corrosion-resisting standpoint."

Longitudinal and transverse sections of both classes of materials are shown in Fig. 2.

Synthetic Acetic Acid and Acetone

Description of the Process and Method of Production of Acetic Acid, Acetates and Acetone From Calcium Carbide—Acetylene Generation and Catalytic Hydration—Oxidation of Acetaldehyde to Acetic Acid—Acetone

By J. T. ROONEY

THE great war was responsible for very many interesting industrial developments in which chemistry played a leading part. The progress of hostilities created demands for some materials greatly in excess of their previous rate of production or even any preconceived ideas of war-time necessity.

The extravagant use of artillery by the British on the western front, using cordite as a propellant, required a great quantity of acetone for the manufacture of this explosive, and it was soon discovered that the supply obtainable from wood distillation was entirely inadequate and new possible sources of manufacture were eagerly sought.

Necessity is said to be the mother of invention and to know no law, and so the urgent demands of war gave birth to many new ideas and fostered many new developments. The manufacture of acetone was undertaken from a variety of new sources, including calcium carbide, molasses, kelp, grain, etc., with varying degrees of success. Probably the most interesting, from a chemical point of view, is that including the synthesis of acetic acid from calcium carbide, water and air.

The various steps in this process had been the subject of much research and several patents before the war, but little had been done up to that time on its commercial development. Subsequent events, however, provided a stimulus which resulted in the synthetic production of great quantities of alcohol, acetic acid and acetone in America, France, Switzerland and Germany.

The Shawinigan Water & Power Co. of Montreal, Canada, which controls a large power development and calcium carbide plant at Shawinigan Falls, was approached by the British War Ministry on the possibility of producing acetone synthetically at Shawinigan Falls. The result was that a subsidiary company called the Canadian Electro-Products was incorporated and, after six months of research by the staff of the new organization, construction was begun and in the following eight months a $2,000,000 plant covering fifteen acres was completed and working to capacity. The plant buildings are of brick, steel and fireproof construction throughout, the floors being of concrete and metal lath and the stairways of iron.

GENERAL VIEW OF THE PLANT

Early in 1918, the Imperial Munitions Board, owing to the great need for acetic acid in the manufacture of cellulose acetate for aëroplane construction, instructed the company to discontinue the production of acetone and to confine its efforts to making acetic acid only.

Reactions of the Process

The synthesis of acetone takes place in four steps:

The production of acetylene from calcium carbide.

$$CaC_2 + 2H_2O = C_2H_2 + Ca(OH)_2$$

The hydration of acetylene to acetaldehyde.

$$C_2H_2 + H_2O = CH_3.CHO$$

The oxidation of acetaldehyde to acetic acid.

$$CH_3.CHO + O = CH_3COOH$$

The formation of acetone from acetic acid.

$$2CH_3COOH = (CH_3)_2CO + CO_2 + H_2O$$

Development of the Process

After the nature and extent of the reactions involved in the various steps of the process had been thoroughly investigated in the laboratory, a small building was allotted for an experimental plant, and in this development proceeded on a semi-commercial scale. It was at this stage that most of the difficulties were encountered and overcome. One of the first problems was the selection of a suitable material for a vessel which would withstand the action of weak sulphuric acid with metallic mercury, and it was found that an acid-resisting silicon-iron was the only satisfactory medium.

Another problem which had to be solved early in the game was the preparation of the yellow mercuric oxide, which acts as a catalyst in the conversion of acetylene to acetaldehyde. This material was required in considerable quantities, and the process of making it from nitric acid and metallic mercury with subsequent conversion of the nitrate to oxide by ignition would have proved a troublesome and costly process on a large scale and consequently new methods of preparation were sought. The process finally developed, and with which very excellent results were obtained, was the electrolytic oxidation, at the anode, of metallic mercury to the oxide, using caustic soda solution as an electrolyte.

Owing to the difficulty of obtaining air-liquefying apparatus for the separation of oxygen from the atmosphere, attention was directed to the utilization of air directly for the oxidation of acetaldehyde to acetic acid, and after many experiments with various metallic containers, numerous catalysts, etc., the task was successfully accomplished. It was found that the reaction could not be controlled in iron, copper, etc., owing to the catalytic action of these metals which was responsible for several explosions at this stage, and it was eventually decided that aluminum was the only metal which could be safely utilized in this capacity.

For the conversion of acetic acid to acetone, numerous experiments were made with oxides and carbonates of calcium, magnesium, barium, zinc, manganese, etc., to determine the most suitable catalyst for the reaction, and the best results were obtained by use of hydrated lime containing a little magnesia.

As in every chemical development, a very considerable amount of work was required to determine the best operating conditions for every step of the process.

Plant Equipment and Operation

The hydration of the acetylene to acetaldehyde is carried out in Duriron kettles, 4 ft. dia. x 12 ft. high, built in circular flanged sections clamped together. In operation, a kettle is filled with water to about three-quarters capacity and sulphuric acid added to make a 6 per cent solution, then mercuric oxide charged in at regular intervals while acetylene is introduced at the bottom of the kettle and allowed to percolate upward through the solution. The mercuric oxide is kept in suspension by the action of the entering gas and by mechanical stirrers. These stirrers, three in number, have paddle blades perpendicular to the shafts, the latter extending to the bottom of the kettle, where they fit into guide sockets. Each stirrer shaft is supported from a collar at the upper end which revolves on ball bearings and is connected with bevel gears to a 7½-hp. motor bolted to a framework on the top of the kettle. The relative weakness of acid-resisting silicon-iron made it impossible to construct these stirrers entirely of this material, and as no other metal was adaptable to the purpose, the difficulty was ingeniously surmounted by the use of a steel shaft over which were fitted sleeves of Duriron, cast in sections with paddles and held tightly together by means of a nut threaded on the shaft.

A rubber gasket between each two sleeve sections prevented leakage of acid to the inner shaft. The lower end of the steel shaft was threaded into an iron nut cast in a piece of Duriron, against which the lowest sleeve fitted tightly.

Acetylene gas is admitted into the bottom section of a kettle through a perforated Duriron pipe and rises through the solution, where it is partially converted into acetaldehyde, the unaltered portion passing out with the aldehyde vapor at the top of the kettle and through condensers and scrubbers into a gasometer, from which it is returned by a Nash hydroturbine to the kettles. Additional acetylene is admitted to the system under pressure at the same rate as the gas is being converted. One charge is operated 50 hr., after which it is dumped and the acid and catalyst renewed. A temperature as nearly 70 deg. C. as possible is maintained in the kettle and the aldehyde, which is boiled off and condensed, runs to brine-cooled containers for storage.

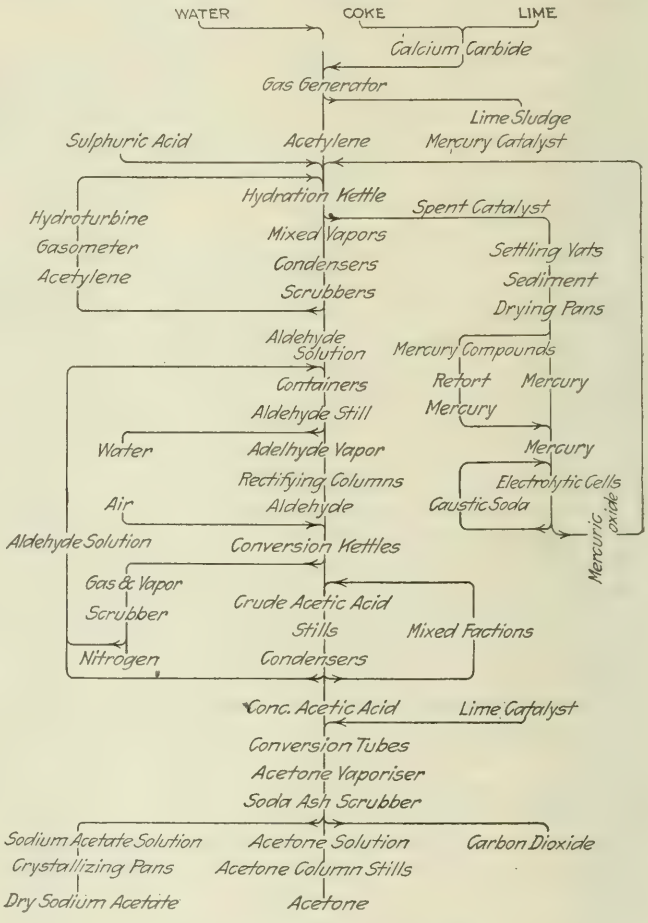
In December, 1918, a disastrous explosion, evidently due to a leakage of acetylene or aldehyde with accidental ignition, wiped out the building in which this part of the process was carried out. Several lives were lost and considerable damage was done.

Acetaldehyde Concentration

Crude aldehyde (from the previous step of the process), a 35 per cent solution in water, is pumped from storage to the still house, where it is concentrated to 99 to 100 per cent and stored again in cooled wrought-iron containers. The motor-driven crude aldehyde pumps are controlled automatically by a float and trip-switch in a small supply tank at the top of the still house. The equipment in this building consists of continuous stills and rectifying columns of cast iron with automatic steam control regulated by vapor tension in the columns. The outlet at the top of the columns is connected to condensers, which are in turn vented to the atmosphere. The addition of a little fine chalk to the crude aldehyde feed neutralized the acidity and added considerably to the life of the apparatus.

Oxidation of Acetaldehyde to Acetic Acid

Pure acetaldehyde, in charges of 1,000 gal., is pumped into heavy iron kettles lined with aluminum, in which the conversion to acetic acid takes place. This part of the process requires the most careful attention of any owing to the extreme sensitiveness of the reaction



FLOW SHEET OF PROCESS

involved and the absolute necessity of the most accurate control. Manganese acetate, ground to 200 mesh, was found to be the most satisfactory catalyst for this reaction.

Air is admitted to the bottom of the kettle under high pressure, helping to keep the catalyst in suspension, and the oxygen is rapidly absorbed. The operation is carried out at a temperature of 60 deg. C. and under a pressure of 65 lb. per sq.in. in the kettle, the pressure being regulated by the rate of admission of high-pressure air and contraction of the outlet of the kettle. The temperature is kept down by circulation of cold water in coils inside the kettle. The dome of each kettle is connected with a set of reflux condensers, which returns liquid aldehyde through a seal to the bottom of the kettle.

The outlet from the kettle is carefully restricted to the cracking of a valve during operation, and the gases which escape pass through a large scrubber, which collects in water any aldehyde that may be carried out with the escaping nitrogen. For safety in operation, each kettle is equipped with duplicate thermometers and pressure gages, which are watched constantly by the operator. There is put into one charge 1,000 gal. of aldehyde, and it requires about 12 hr. to reach an acidity of 95 per cent in terms of acetic acid. It is then considered finished and is dumped. So completely is the oxygen absorbed from the air in this operation that the scrubber gas content seldom exceeds 0.1 per cent. In spite of every precaution, fatal explosions and fires have occurred in this building.

Acetic Acid Refining

The crude acetic acid containing small amounts of aldehyde, manganese acetate, water, etc., is refined by fractional distillation in copper stills with aluminum fractionating columns, dephlegmators and condensers. The aldehyde fraction comes off first and goes to the aldehyde storage; mixed fractions are run with a subsequent charge. Water-white acetic acid, 99.8 per cent pure, is produced by this distillation.

Production of Acetone

In this step of the process, vaporized acetic acid is passed through a heated tube containing a catalyst which effects the decomposition of acetic acid with the formation of acetone, the products passing through a hot scrubber containing soda ash, which converts the unaltered acetic acid into sodium acetate and allows the acetone to pass through into condensers, from which it is obtained in a 20 per cent solution. When this operation was tried on a large scale it was found that the larger conversion tube, measuring 12 in. dia. x 13 ft. in length, did not function so well as the experimental one which had been made from a 4-in. wrought-iron pipe. In the larger installation, steel tubes were used covered with asbestos and mica and wound with 290 ft. of No. 12 nichrome ribbon. The winding was made in several parallel circuits for convenience in temperature control. These tubes were packed with pumice on which the catalyst, hydrated lime, was deposited, but owing to the poor conductivity of the pumice it was impossible to maintain the required temperature of 485 deg. C. A central heating core was then added, but even this did not have the required effect, and the pumice was finally replaced with iron balls coated with lime. Seventy-two such conversion tubes were installed, requiring 12 to 15 kw. each for heating, and these gave a daily production of ten tons of acetone of great purity with an operating efficiency of 85 per cent for the entire period of production. It was necessary, in this process, to renew the catalyst about every two weeks.

Preparation of Mercuric Oxide

The yellow mercuric oxide catalyst used for the conversion of acetylene to acetaldehyde is prepared by the electrolysis of a caustic soda solution in circular cast-iron cells, 6 ft. dia. x 15 in. deep, having the inside walls lined with cement.

A layer of metallic mercury on the bottom of the cell serves as anode. A large sheet-iron cathode, like a spider web in appearance, is suspended below the surface of the electrolyte.

A stirrer revolves between the electrodes to remove the oxide formed from the surface of the mercury and to keep it in suspension. At the end of a run the oxide is washed from the cell with a hose and settled in vats, from which it is used directly in the wet condition. The caustic soda is used repeatedly.

Recovery of Mercury

The recovery of the mercury was another problem involving many difficulties and for which quite an extensive equipment was required. When a charge containing the spent catalyst is dumped from an acetylene conversion kettle it is settled in conical wooden vats, after which the supernatant liquid is siphoned off and passed through a series of settling tanks to catch all the mercury possible. The sediment remaining in the conical vats, consisting of metallic mercury, mercury compounds, etc., is then neutralized with soda ash and charged into covered, steam-jacketed drying pans fitted with stirrers and operated under a full vacuum. When the contents of these pans have been dried, metallic mercury is run off and the remaining material then charged with reducing agents into retorts for distillation. These retorts are oil-fired and the pots were at first made of cast iron, but this material had a very short life and the expense of renewal was excessively high, but later nichrome alloy pots were tried out and gave more efficient service in spite of the greater initial cost.

The extensive handling of mercury in the various steps of the process was the cause of much sickness until proper precautions had been studied and enforced.

A Notable Achievement

This undertaking of the Shawinigan Water & Power Co. was a notable achievement, both from the point of view of the success attained and the remarkably short transitional period from the laboratory research stage to one of large-scale production. It is also a striking example of the major rôle played by chemistry in modern warfare and a proof that Canada did her "bit" in the laboratory as well as on the battlefield. The frequent necessity for use of the regulation army gas mask for protection against lachrimatory gases such as croton-aldehyde, etc., contact with the poisonous mercury catalyst and the ever-existent danger of explosion or fire presented a parallel for life in the trenches and a casualty list equally as deserving of an enduring place on the roll of honor.

When the United States Government entered the war and planned a huge aërial program, great quantities of acetic acid were required for manufacture of cellulose acetate varnish, and it was found expedient, by

CONVERSION TUBES AND EVAPORATION POTS

arrangement with the Shawinigan Water & Power Co., to duplicate, on the spot, the plant at Shawinigan Falls.

This new plant, called the American Electro-Products Co., was about completed and ready for operation when the armistice was signed. So well had the development of the process been carried out in the beginning that, even with the experience gained by a year's operation, only minor variations from the original design were found necessary in building the second plant. The combined plants have a capacity of more than fifty tons of glacial acetic acid per day.

Conclusion

The products of the various steps of the process form possible bases for the manufacture of an unlimited variety of valuable organic chemicals, and the apparatus, in excess of that required to supply a normal acetic acid demand, might readily be adapted to the manufacture of countless new products.

In cost of production, the synthetic process, when associated with the carbide industry, can at present about hold its own with the wood-distillation process and should ultimately entirely displace the latter.

Extensive research by a large staff is now being carried on in the well-equipped laboratories and experimental plant of the Canadian Electro-Products Co. and the company looks with every confidence to the future.

Canada's Foreign Trade for 1919

THE value of Canada's foreign trade in the year ended Dec. 31, 1919, exceeded that of the previous twelvemonth by $82,049,160. Imports in 1919 aggregated $941,007,700, or $30,858,560 more than in the preceding year; exports, $1,241,085,606, or $41,449,143 more; and re-exports, $53,834,766, or $9,741,457 more. With the exception of the record year of 1917, the values for 1919 exceeded those of any other year of the last decade, as Table I shows.

The balance of trade in favor of the Dominion in 1919 was $353,912,672. In trade with the United States, however, Canada had an adverse balance of $285,893,931. That adverse balance has been a potent factor in determining the rate of exchange between the two countries.

The extent to which the various countries of the world participated in Canada's foreign trade during the past three years can be seen from the totals presented in Table II.

Canada during the past year extended credits of $25,000,000 each to Belgium, Rumania, Greece, and France. Orders were placed under these credits as follows: Belgium, $1,734,295; Rumania, $22,373,467; Greece, $8,118,940; France, $5,519,047.

The development of the market for Canadian goods in the United States is emphasized by the figures for the year just closed. The returns show total exports from Canada to the United States for twelve months ended Dec. 31 last amounting to $454,686,294, compared with $433,182,140 in 1918, an increase of $21,504,154, and with $401,479,287 in 1917, an increase of $53,207,007. Imports from the United States for the year at $740,582,225 show an appreciable decline as compared with 1917, when they were $829,847,747, a decrease of $89,265,522, but, compared with 1918, there was only the small decline of $756,079.

This situation is in marked contrast to the trade done with the United Kingdom. For the year the exports to Great Britain and Ireland amounted to $528,035,514, compared with $568,820,873 in 1918, a decrease of $40,785,359, and, compared with $873,706,892 in 1917, a decrease of $345,671,378. Imports from the United Kingdom for the past year at $87,516,819 were higher than in 1918 by $14,637,710, but were lower than in 1917 by $3,619,909.

The large decline in exports to Great Britain is explained by the elimination of huge shipments on war account in both 1917 and 1918, though it is encouraging to note that the shipments of peace-time goods are now showing a substantial, if gradual, gain.

TABLE I. CANADA'S IMPORTS AND EXPORTS, 1910-1919

Calendar Years	Merchandise Imports			Merchandise Exports		
	Dutiable	Free	Total	Canadian Produce	Foreign Produce	Total
1910	$269,759,731	$165,441,076	$435,200,807	$279,859,593	$15,554,838	$295,414,431
1911	320,452,211	183,036,549	503,488,760	279,446,816	17,121,211	296,568,027
1912	418,021,349	218,668,576	636,689,925	341,980,882	20,984,698	362,965,580
1913	438,539,132	221,364,984	659,904,116	436,218,067	24,301,179	460,519,246
1914	302,516,964	179,431,624	481,948,588	379,295,854	49,019,658	428,315,512
1915	261,842,173	189,042,855	450,885,028	614,129,845	39,358,567	653,488,412
1916	422,173,311	345,203,358	767,376,669	1,091,706,463	20,738,599	1,112,445,002
1917	557,636,509	448,394,360	1,006,030,869	1,547,340,855	46,155,194	1,593,496,049

The Commercial Synthesis of Sillimanite*

A Description of a Cupola Process for Fusing Alumina and Silica to Form Sillimanite Crystals — Reactions Consist of Forming Carbides Under Reducing, and Combusting Them Under Oxidizing Conditions

By ANDREW MALINOVSZKY

VERY little work has been done on the conversion of the double oxides of alumina and silica or alumina and magnesia into stable crystal phases such as sillimanite and spinel. Many ceramists have tried to mix, without actually fusing, alumina and silica, molecule for molecule, to obtain sillimanite, or alumina with magnesia, to form spinel. Stoichiometrically these mixtures may be made to represent the analytical composition of sillimanite and spinel crystals perfectly, but physically such mixtures are far from having the stable properties of either. The products obtained in such a manner exhibit no more stability than their individual components.

No advantage whatsoever can be claimed for mere physical mixtures of alumina with silica, or alumina with magnesia. The real value of such a combination is obtained only if the components are interdissolved by fusion. Solidifying from solution, the molecules arrange themselves into their stable crystalline phases.

It should be clearly understood that when alumina and silica, or alumina or magnesia, are mixed and exposed, after they have been shaped into brick, to any temperatures lower than fusing, neither new molecular combinations nor crystalline compounds will be made. When such a heterogeneous mixture is made into refractories and placed in service in a furnace, where it is exposed to sudden thermal changes, to slag, to alkaline vapors, or to any other destructive agents existing in a commercial furnace, it will be quickly acted upon and soon destroyed.

Fluxed Sillimanite Not Desirable

The suggestion has been made by a few ceramists that old glass pots be used, pots in which the free silica has been dissolved by the alkalis of the glass, leaving behind a magmatic solution from which sillimanite crystals have formed after the pots were cooled. The addition of such sillimanite is of no more value to the newly built pots than that of common grog. It stands to reason that sillimanite crystals produced from such a magmatic solution in the intimate presence of fluxing solvents are not stable, and their presence can then be of no value. Sillimanite crystals formed under such conditions will be dissolved well below their fusion temperature of 215 deg. C. by the fluxing action of the intimately associated low melting point substances, if heated to a temperature where the adjacent material from which the sillimanite crystals separated out is in the liquid state. In other words, the sillimanite crystals formed as stated above will be attacked by the surrounding material whenever the temperature at which it becomes liquid is reached. It will then act as a solvent for the sillimanite crystals, and the whole mass will fuse at a temperature far below the fusing temperature of sillimanite.

Stable sillimanite or spinel crystals are obtained only when their components are liquefied at the fusing temperature of alumina and silica, or alumina and magnesia. The fusion should not be produced by any fluxing agent, but only under the action of heat at the required temperature of approximately 1,815 deg. C. or above. For illustration, take porcelain bodies containing sillimanite crystals, concerning which many theories have been advanced. Those investigators who came to the conclusion that sillimanite crystals are formed only from an acid solution of silica and alumina, and not from a viscous slag, have demonstrated the actual facts. Adding lime or magnesia does not develop the crystals; it only promotes the liquefaction of the magma. If the body or mix should be brought into a liquid state without the addition of these bases the crystals would have been better developed.

Factors Influencing the Development of Sillimanite Crystals

Many experiments along this line have demonstrated that the presence of a high percentage of lime actually retards the development of the sillimanite crystals. Most authors and investigators have laid great emphasis on the importance of feldspar as favoring the development of sillimanite crystals, for without feldspar no sillimanite crystals seem to be formed in a porcelain body. This statement holds good for porcelain bodies, glass pots and firebricks, as the feldspar dissolves the kaolin and also the flint. At the same time, with porcelain it is demonstrated that lime acts as a retarder in the formation of sillimanite crystals. For in the glass covering the porcelain bodies, sillimanite crystals are never found, but close under the glass more sillimanite than anywhere else in the same body is found to occur.

Sillimanite crystals much larger in size (length and diameter) can be produced without the presence of feldspar, mica, lime or any other fluxing material than when these materials are present. It should be borne in mind that if the components of sillimanite are heated up to their boiling temperature, as is the case in the process about to be described, it is evident that considerable molecular activity must be produced. In building up the sillimanite crystals, the molecules of alumina and silica must follow their turn in the force of the molecular attraction. Thus they become regularly arranged groups of molecules in harmonious vibrating or oscillating relation with one another, and so one molecule after the other comes into equilibrium with one another until the whole magma has been formed into a solid form of a crystalline structure.

The method by which artificial sillimanite crystals are produced consists of crushing aluminous minerals from

*An excerpt from the paper read by the author, entitled "Fused Artificial Sillimanite," before the American Ceramic Society, Philadelphia, Feb. 23, 1920.

1 in. in diameter down, and smelting in a cupola furnace together with a suitable reducing agent in a required amount. It is possible to regulate the volatilization of the silica by proportioning the amount of reducing agent, so that it shall be sufficient to reduce all or a fraction of the silica, leaving only a part of the silica unreduced, so to convert all the charge into sillimanite upon oxidation and fusion.

For instance, the crushed raw material is mixed with coke, the carbon being approximately in molecular proportion to the oxygen contents in the rock or minerals, as indicated in the following equations:

$$2Al_2O_3 + 4SiO_2 + 14C = Al_4C_3 + 4SiC + 7CO_2$$

which upon combustion will give the following with a heat of reaction that will fuse the products:

$$Al_4C_3 + 4SiC + 14O_2 = 2Al_2SiO_5 + 2SiO_2 + 7CO_2$$

The proportion of the mixture is varied, as an excess of carbon over the calculated amount of silica is necessary in order to complete the reductions, as the raw material may contain some iron, lime, etc. On the assumption that the above reactions take place, it is evident that everything present is reduced to carbide. After the carbides are formed, they dissociate, though less rapidly than in the pure state. It depends on the ratio of the combined carbon and the effect of silicon and aluminum upon the quantity and condition of carbon. When SiC gives up its Si, leaving behind C, the silicon ignites spontaneously on coming in contact with the air blast, forming first SiO then SiO_2.

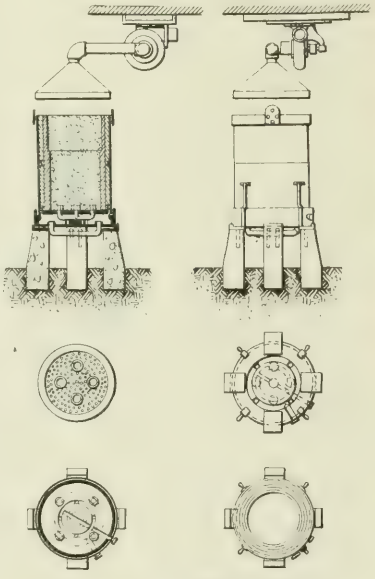

FIG. 1. FURNACE SECTIONS

The reactions between silicon and oxygen are very violent and much heat is produced by the combustion. If iron is present, it usually alloys with silicon and it is either volatilized or sinks to the bottom of the furnace.

Furnace Used for Fusion

Sections of the furnace are shown in Fig. 1. The outside of the furnace is of common iron such as an old boiler shell, or an old smokestack can be used. This is lined with good firebrick. The bricks are then protected with a layer of about 4 in. of the pulverized material to be fused. A tapering mold is placed inside the furnace and the raw material is rammed all around between the furnace and the mold to about 1 in. thick on the top. This will protect the firebrick and at the same time prevent the fused mass from adhering to the firebrick, so it can be discharged freely in a very short time. When the ramming is finished the mold is removed. The gratebars are covered with a layer 1 ft. deep of large lumps of coke. These lumps of coke are placed on the grate bars to protect them from the heat of the fusion zone. Coke is the best fuel for the process, as it does not crush or disintegrate and carries the weight of the charge better than coal. The coke, which has about 44 per cent of voids, proves advantageous in preheating the air.

A 3-ft. layer of fine coke is placed over the coarse layer, then a little kindling wood, on top of which about 16 in. of fines are spread and the fire lighted. The blower is started very slowly at first. After the coke is ignited, the crushed raw material mixed with the crushed coke is fed into the furnace and the speed of the blower is gradually increased to furnish about 18,000 to 28,000 cu.ft. of compressed air per hr. under from 3 to 6 lb. per sq.in. of pressure. In about 2 hr. the charge sinks down and the gases burn in flames above the surface. The blast of the compressed air is forced through the 64-in. fuel bed of coke, being

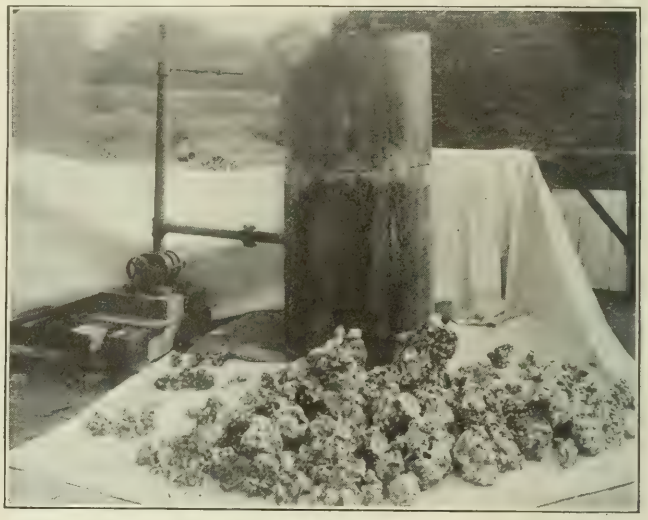

FIG. 2. CUPOLA AND BLOWER, REMOVED SILLIMANITE CHARGE

very well preheated, and so forced through the hot reacting zone under favorable conditions.

The silica is observed condensing on the furnace wall. This period is characterized by the yellow flame coming from the furnace, which later changes to violet and then white. It is very important in this process to have the heat come from the bottom of the furnace. Enough fuel should be bedded at the start to supply the whole process. The furnace must be maintained under such reducing conditions in the beginning as to gradually convert all the elements present to carbide. It should be understood that reduction takes place only at temperatures where solid carbon takes up oxygen from the material. After 3 or 4 hr. the whole charge is brought to a dazzling glowing white heat, the yellow and violet flames indicating the combustion of the Si to SiO and then to SiO_2.

The contents of alumina and silica boils violently, which is made evident by the roaring noise inside the furnace. The silica is volatilized in dense bluish white and later brownish fumes for about 2 hr. After 5 or 6 hr. the reactions are completed and the air is blown into the cupola through the cooling fused mass in order to produce cells resembling diatomaceous earth. The specific gravity of this fused mass varies from 2.62 to 2.86.

The furnace is provided with an exit pipe through which the fumes of silica, potash, sodium, etc., if present, together with the other gases, are withdrawn to a settling system, where they are separated.

From this process it is possible to effect a complete separation between the fused mass, alkalis and silica, if desired, which is a more economical process than the electric furnace. The hood of the furnace can be removed freely to both sides and also lowered or raised. The hood is suspended above the furnace, and suction is applied so as to collect all the fumes. By this means the cupola is aided by a blast at the bottom and suction at the top.

The fused mass can be removed in different ways, as the cupola is so designed as to accomodate varying conditions. The mass can be removed at the bottom with the cupola in place, or the cupola can be removed and leave the chilled fused mass standing in place on the grate bars, or the mass and cupola can be removed, and another cupola, all ready charged, set up on the place, and another operation can be started. With this system a continuous process is established.

Fused Sillimanite

After the fused sillimanite is removed from the furnace it is broken up in a jaw crusher and then reduced to the required fineness. Any metallic iron present is separated out by a specially designed magnetic device.

FIG. 3. SILLIMANITE PRODUCED FROM ST. LOUIS FIRE-CLAY. × 114.

The fused sillimanite obtained by this process is a very stable compound and highly refractory, free from uneven expansion and contraction strains at any temperature.

This process of making artificial sillimanite crystals has also developed some doubts as to whether the crystal development is due only to the influence of slow cooling, as has always been hitherto believed. In the science of petrology it is taught that the volcanic rocks which were cooled on or near the surface of the earth solidified so quickly that the rocks show very small crystals or none at all, often with open texture. Obsidian, which is a glassy lava sometimes called volcanic glass, resembling bottle glass, showing no crystal development, is a typically extreme case. It is composed of from 65 to 78 per cent of SiO_2, from 12 to 17 per cent of Al_2O_3, the remainder being different oxides of iron, calcium and others. The plutonic rocks, on the other hand, solidified deep below the surface, had time to cool slowly and develop a coarse crystalline structure with a very close texture.

The cooling rate theory is not checked with this process, where the mass is brought to the boiling point in from 5 to 6 hr. and cooled down in 1 hr. by a cold blast with 5-lb. pressure to a porous mass resembling pumice in its appearance, having a coarse crystalline structure with the largest sillimanite crystals ever produced. The accompanying illustration, Fig. 3, demonstrates the development of sillimanite crystals from fire clay. The square needle-like formation is very distinctly shown.

Production of Turpentine From Douglas Fir Pitch

Old growth yellow fir stands in certain timber districts of the Northwest contain a large number of what are known as "pitch trees." These trees are usually alive and free from noticeable decay, but frequently rough, burly and quite often twisted or bent well up the trunk, and contain, within a distance of several inches from the surface, pockets or seams filled with pitch. The pitch can be drained from the trees by boring into the seams with an auger, and the pitch collected in receptacle provided for this purpose.

The Northwestern Turpentine Co. has begun operations in a small way in collecting pitch from fir stands and in the production of turpentine and rosin. The pitch is collected from timber under lease, providing that all holes bored in trees shall be plugged after the pitch is removed and that all possible efforts be made to prevent fire hazard. The pitch is transported to Portland in barrels for treatment. The turpentine is recovered from the pitch by distilling with live steam. After the turpentine is removed a commercial grade of rosin is obtained from the residue. The pitch will contain about 25 per cent by volume of turpentine, and about 70 per cent by weight of rosin. In addition it is possible to obtain a small amount of "balsam."

Artificial-Silk Manufacture in Great Britain

The manufacture of artificial silk is being undertaken by the British Cellulose & Chemical Manufacturing Co. at its factory at Spondon, near Derby. Samples of silk thread produced at Spondon have been submitted to weavers, who state that it is of such texture and quality that when converted into articles of clothing they will have the appearance and finish of natural silk. When fully developed the factory at Spondon will employ a large number of workers and produce nine tons of artificial silk a day. Other products which the company is manufacturing, or intends to manufacture. according to the London press, include non-inflammable films, synthetic perfumes, and aspirin; of the last named, six tons per week is being turned out from the company's works.

Mexican Commercial and Industrial Exposition in 1921

The Ministry of Industry, Commerce and Labor has begun preparations for a commercial and industrial exposition to be held in Mexico City in September, 1921, in commemoration of the first centennary of Mexican independence. According to the data given to the press, the exposition will be entirely national in character, and will be confined to exhibits of Mexican raw materials and manufactured products. Invitations are to be extended to all foregin Governments and to chambers of commerce of the principal cities to send representatives to attend the exposition.

Legal Notes

By Wellington Gustin

A Lesson on Filling Orders

In an action by the Burley-Winter Pottery Co. against the Onken Bros. & West Co., the Supreme Court of Wyoming has affirmed the judgment against the pottery company. (183 Pac., 747.)

The pottery company manufactures pottery, crockery, glassware and similar products at Crooksville, Ohio. It charged that it sold and shipped the wholesale house in Wyoming a car of stoneware on a written order.

On the trial the defendant objected to the introduction of the order as evidence on the following grounds:

1. That it is not shown that the person signing the same had any authority to give the order.
2. That the alleged order is void for uncertainty.
3. That it fails to disclose the price of the goods.
4. That there is no sufficient description of the goods.
5. That the order, being for more than $50 is void under the statute of frauds.

Since this contract was one coming under the statute of frauds the order was not admitted and plaintiff was unable to prove its case.

The provisions of this statute of frauds, which should be known and committed by every business man, are:

Provisions of Statute of Frauds

"Any contract for the sale of goods, chattels or things in action for the price of $50 or more, shall be void, unless:

"First. A note or memorandum of such contract be made in writing and be subscribed by the party to be charged thereby; or

"Second. Unless the buyer shall accept and receive part of such goods, or the evidences, or some of them, of such things in action; or

"Third. Unless the buyer shall at the time pay some part of the purchase money."

A Sales Contract Must Be a Signed Memorandum of Sales

The order offered in evidence called for "One car stoneware as per orders shown for same at ¼c. per gal. less than prices sold at" and was signed "Onken Bros. & West Co., Successors to J. E. West Co., Inc., per E. W. Elder."

Plaintiff charged that the goods were sold by its salesman at an agreed price. But the Supreme Court said that in the order, as offered in evidence, the description of the subject-matter of the contract is too indefinite to fulfill the requirements of the statute. "One car stoneware may mean any kind or several kinds of stoneware, and the property could not be identified without other evidence. Nor does the additional statement, 'as per orders shown for same,' render the description of the property any more definite. The names of the parties giving the orders are not stated; but, if that had been done, the orders referred to were not offered in evidence. The order offered in evidence not being such a memorandum as is required by the statute, it was properly excluded. In addition to the insufficiency of the memorandum, there was no competent evidence of a delivery. The only evidence of a delivery was the testimony of the salesman who took the order that to the best of his knowledge the goods, the carload, was shipped according to the orders he had taken. But he admitted he had no personal knowledge of the shipment, was not present, and in fact knew nothing about the shipment."

Rickey vs. Moon Clay & Kaolin Co.

The Court of Errors and Appeals of New Jersey has affirmed the decree of the Court of Chancery in favor of Walter H. Rickey against the Moon Clay & Kaolin Co. and others. It appears that Rickey obtained an option agreement from defendant Moon in 1913 whereby Moon agreed to sell his clay lands in Hamilton township at any time within two years for $6,000 per acre for the best clay lands and $1,000 per acre for the balance. This option was extended and Rickey interested defendant Muschert and persuaded him to secure a loan of $3,000 upon promise to pay Muschert one-tenth part of the profits on the option agreement. Then Rickey got a commission agreement from Moon wherein the latter agreed to pay 10 per cent commission upon all sales of his land. Thereafter the complainant Rickey and Muschert and J. L. Conard entered into what was called the three-party agreement wherein it was stipulated that Muschert was to hold the Moon-Rickey agreements for the benefit of the three, subject to the lien of the loan mentioned. Rickey and Conard were to give their attention and efforts, Conard his professional skill as a lawyer, in advancing the enterprise, which was understood to be defending condemnation proceedings of the Pennsylvania Railroad. Out of the profits Muschert was first to retain $10,000, made up of the $3,000 advanced as a loan, $5,000 advanced to Conard and $2,000 to be later advanced. The agreement then provided that all of the profits should be divided among the three, share and share alike, after the deduction of the $10,000 above mentioned.

The condemnation proceedings failed of realization, and then Muschert, Conard and Moon formed the Moon Clay & Kaolin Co. and took over the clay lands for $206,000 of the capital stock of the company, under arrangement with Moon that he was to sell his holdings to Muschert and Conard for about $50,000. The clay company is now owned by Muschert and Conard, and is operating the clay pits. The complainant Rickey was not permitted to participate. He was practically frozen out, said the court. He then filed his bill to impress the trust of the three-party agreement and for an accounting.

Agreement Involved

The defendants Muschert and Conard answered setting up Rickey's 10 per cent commission agreement, and claimed that they were operating under it in connection with the three-party agreement. They said they were willing to assume Moon's obligation to pay the commission on a sales price of $206,000 to be divided equally between the complainant Rickey and Conard and Muschert, after deducting the $8,000 advances of Muschert. The agreement called for $10,000 to be deducted in favor of Muschert, but this included $2,000 which he was later to advance but did not. The three-party agreement shows clearly the final arrangement of the parties, said the court, and this was that all over the $8,000 was to be divided share and share alike. One-third was, therefore, adjudged to Rickey.

Synopsis of Recent Chemical & Metallurgical Literature

Large Mixer in New French Steel Plant.—*Engineering* (London) has presented considerable information regarding the new modern steel plant of the Société Normande de Métallurgie, Caen, France, in its issues, vol. 107, p. 136, vol. 109, pp. 180 and 292. The accompanying figure is an interior view of the craneway covering the casting pits for open-hearth furnaces, arranged in the left background. Nearer is the pouring side of a 700-ton mixer, for use as a reservoir for the bessemer converters. The mixer itself is 4.83 m. diameter, 8.23 m. long inside brick lining (15 ft. 10 in. x 27 ft.), fired by blast-furnace gas and hot blast from a regenerative checkerwork. Besides main pouring spout there

MIXER IN A MODERN STEEL PLANT

is an auxiliary charging mouth on the same side, while opposite is the main charging mouth and a slag spout. all of which are closely fitted with covers. The block containing gas and air ports is on wheels so it can be moved away from the opening into the mixer, but sufficient clearance at the flue connection is left so that this device is not necessary. The view also shows the traveling mast cranes used almost exclusively about the plant for such purposes as stripping, soaking pit service, billet and charge box handling. The extensive use of reinforced concrete in the building construction may also be clearly seen.

Smelting and Refining of Cobalt Silver Ore.—At the Deloro Reduction Co.'s smelter, silver cobalt ore is smelted in a blast furnace (run with 6-8 oz. blast pressure on account of the large proportion of fines), the charge being calculated to furnish speiss and a neutral slag. The speiss contains Co, 22-25; Ni, 16-18; As, 25; Fe, 18; S, 7; Cu, 1 per cent, and 1,000-2,000 oz. Ag per ton; it is first liquated to recover part of the silver, then ground, roasted, chloridized, washed with water, and treated with cyanide. The silver is precipitated from the solution with aluminum dust, the cyanide being almost quantitatively regenerated. The liquated and the precipitated metal are melted in an oil-fired furnace which is tilted backward into blowing position; the metal after 3 hr. blowing is 992-995 fine, and is refined by another melting. The desilverized speiss is sulphatized and leached; the liquor is first freed from copper and iron, cobalt precipitated with hypochlorite solution, and nickel, after removal of the cobalt, with milk of lime. The hydroxides are filter-pressed, washed, and dried ready for sale, or mixed with charcoal and reduced; the crude metals are separated magnetically from excess of carbon, re-melted in electric furnaces, and granulated by pouring into water. The dust and fume from the various furnaces, collected in a baghouse, are heated in a coke-fired reverberatory, and the pure arsenic trioxide condensed in chambers. The clinker from this operation goes back to the blast furnace for the recovery of silver.—S. B. WRIGHT, *J. Soc. Chem. Ind.*, vol. 38, p. 77A.

Canadian Mineral Production for 1919.—A digest of the 1919 statistics of the Canadian Department of Mines is given in the *Canadian Mining Journal.* The year has been one of transition from a war to a peace basis and the difficulties of making the necessary adjustments have been aggravated by social unrest and by strikes, these resulting in a decrease in the production of metals, coal and minerals during the year. On the other hand, structural materials, asbestos, gypsum and salt showed increases.

The value of products classified as structural materials and clay products was $25,755,000; as non-metallics, $74,919,000; as metallics, $72,402,000 — a total of $173,076,000, a decrease of $38,226,000, or 18 per cent, from that of 1918. The greatest decrease was in the production of nickel and copper; the decrease in value of the products classified as metallics amounted to 37 per cent.

In the amount of the individual metals produced, copper showed a decrease of 37 per cent; gold, with a total production of 767,167 oz., an increase of 10 per cent; lead, with a total production of 43,895,888 lb., a decrease of 15 per cent.

The production of nickel for 1919 was 44,452,953 lb., compared with over 92,000,000 lb. in 1918; of this, 5,063 tons was refined in Canada, compared with 1,204 tons in 1918. The new refinery of the British-American Nickel Co. at Deschenes, Que., which will soon be in full operation, will have a capacity of 7,000 tons of nickel and 3,500 tons of copper per year. There will also be a precious metal refinery, and platinum, palladium, iridium, gold and silver will be produced.

About 25 oz. of platinum and 62 oz. of palladium were produced during the year. Silver production was 15,675,134 oz., compared with 21,383,979 in 1918. The Ontario production was 76.1 per cent of the total. The zinc produced was 15,869 tons, a slight decrease.

The output of iron ore was, from the Canadian point of view, most disappointing, being the lowest recorded for nineteen years and amounting to but 195,970 tons. Of the iron ore charged to blast furnaces but 4.4 per cent, or 78,000 tons, was of domestic origin. Of the imported ore, 519,722 tons came from Wabana, N. F., and 1,154,473 from the United States.

Of asbestos, 153,069 tons of crude and milled fiber was produced, valued at $10,723,032, compared with 143,456 tons in 1918, valued at $8,870,707.

Canada produces less than half its total coal consumption. For 1919 the total used was 28,768,099 tons; of this, 13,586,300 tons was produced locally. The production of byproduct coke shows an increase during the year; sixty Koppers ovens were completed

at Sydney, twenty-five Willputte ovens at Sault Ste. Marie, and thirty Lomax ovens at Anyox, B. C. Imports of coke decreased from 1,165,590 tons in 1918 to 383,374 tons in 1919.

During the year there was a decided increase in production of all structural materials such as cement, clay products, lime, sand-lime brick and building stones.

Of salt, 148,302 tons was produced, which is an increase of about 10 per cent over 1918. The discovery of potash mineral associated with the salt deposit at Malagash is attracting considerable interest. The Brunner-Mond (Canada) Co. completed and placed in operation a plant at Amherstburg, Ont., for the manufacture of soda ash from brine.

The crude oil production was 240,970 bbl. (35 Imp. gal.—42 U. S. gal.), of which 90 per cent came from the oil fields of southern Ontario. Canada imported about 13,000,000 bbl. of petroleum oils, crude and refined, during 1919, an increase of 857,000 bbl. over the previous year.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Reserve Dry Cell.—The cell consists of two parts—a zinc container which serves as the negative electrode when the cell is in use, and a bobbin or cartridge containing the positive carbon electrode and the usual mixture of carbon, electrolyte and manganese dioxide. This bobbin is provided with a thin paper wrapper and is dipped in a celluloid solution so that a waterproof coating is formed which prevents evaporation of the electrolyte. The upper part of the cartridge is sealed with pitch held in place by a band of zinc having a projecting peripheral bead which is designed to engage with a similar bead on the zinc container and thus lock the parts. The interior of the zinc container is coated thinly with flour paste. When it is desired to use the cell, the bobbin is taken out, the celluloid coating and paper wrapper removed and the bobbin replaced after having added sufficient water to the zinc container to thoroughly moisten the coating of flour, which now serves as a filler between the zinc and the mix. (1,329,946; HARRY D. BATCHELOR of Lakewood, Ohio, assignor to National Carbon Co.; Feb. 3, 1920.)

Stabilizing Lead Azide Detonators.—When mixed with blasting gelatine, lead azide may be handled safely and yet it retains its powerful detonating properties. From 1 to 20 per cent of blasting gelatine may be used, according to consistency desired. (1,329,525; WALTER G. HUDSON of Wilmington, Del., assignor to E. I. du Pont de Nemours & Co.; Feb. 3, 1920.)

Sodium Compound of Salvarsan.—The use of salvarsan is attended with certain disadvantages. The compound is sold as the dihydrochloride, and this acid must be exactly neutralized just prior to injection. The neutral solution cannot be kept, since oxidation proceeds rapidly, with the formation of a violent poison. Neo-salvarsan may be used directly, but is less effective. UMETARO SUZUKI of Tokio, Japan, prepares the sodium compound of salvarsan in the following manner: 5 g. of diamino-dihydroxy-arsenobenzene-dihydrochloride, $(C_6H_3NH_2OHAs)_2.2HCl$, is dissolved in alcohol and treated with sodium ethylate or methylate until a few drops give a clear solution in water. The whole liquid is poured into ether and 5 to 6 g. of yellow-brown precipitate is obtained. The operations should be carried out in a non-oxidizing atmosphere. The compound is soluble in water and physiological salt solution and contains from 22 to 23 per cent arsenic. It does not require neutralization and there is no tendency toward the formation of poisonous compounds through oxidation. (1,330,288; Feb. 10, 1920.)

Production of Cyanides.—Of the many compounds present in the reaction product of the Bucher process, only sodium cyanide is soluble in liquid ammonia. The extracted residue may be returned to the process. Indeed, the catalyst seems to improve. Prior to and during the leaching process, air must be excluded, as cyanate will be formed. This is also soluble in liquid ammonia. (1,329,652; JOHN C. CLANCY of Freeport, N. Y., assignor to the Nitrogen Corporation; Feb. 3, 1920.)

Rust-Preventing Solution.—Oxidation of iron and steel structures such as bridges and freight cars can be arrested by spraying with a solution composed of 70 parts of 50 per cent phosphoric acid, 20 parts of glucose or glycerine with sufficient water to make 100 parts, all by weight. After 24 hr. the surface is washed with strong soapy water, dried and oiled or painted. (1,329,573; WILLIAM H. ALLEN of Detroit, Mich.; Feb. 3, 1920.)

Stable Nitrostarch.—The carbohydrate material is subjected to a preliminary treatment whereby it is swelled or puffed in a manner resembling the puffed cereals now on the market. The porous condition permits nitration to proceed quickly and uniformly. Mixed acid containing 30 per cent HNO_3, 64 per cent H_2SO_4 and 6 per cent H_2O is used at a temperature of 40 deg. F. The carbohydrate material is kept beneath the surface of the acid by means of a perforated plate. The nitrated product is separated by removing the perforated plate and pouring water gently on the surface of the acid. The product floats on the water and is removed, washed and boiled in two successive baths of very weak acid. The product is now stabilized by boiling in a solution of a sodium soap. Further washing is followed by centrifuging and drying at 100 deg. F. (1,329,353; GEORGE R. ANCHORS of Landing, N. J.; Feb. 3, 1920.)

Manganese Dioxide Depolarizer.—Under certain conditions, the reaction between a manganous salt and sodium hypochlorite may be made to yield a deep black dioxide having good conducting properties. The hypochlorite solution is preferably added to a boiling slightly acid solution of $MnSO_4.4H_2O$ of such a concentration that the boiling point is about 103 deg. C. (1,330,738; CARLETON ELLIS and ALFRED A. WELLS of Montclair, N. J., assignors by mesne assignments to National Carbon Co.; Feb. 10, 1920.)

Recovering Sulphonic Acids From Mineral Oil Sludge.—Sludge produced in sulphonating mineral oil is dissolved in water (100 parts sludge to 150-200 parts H_2O) and allowed to stand for 8 to 12 hr. Heat is generated, SO_2 is evolved and the free oil rises to

the surface and is decanted. The solution is neutralized with lime and the precipitated calcium sulphate filtered off. The clear wine-colored solution contains the calcium sulphonate, which may be salted out by adding sufficient calcium chloride. The product is water-soluble and may be used for saponifying purposes or for the production of detergents suited for use in salt water. (1,330,624; ROBERT E. DIVINE of Cincinnati, Ohio, assignor to the Twitchell Process Co.; Feb. 10, 1920.)

Destructive Distillation of Wood.—In order to prevent "cracking" of the oils and gums formed during the destructive distillation of wood, DAVID L. HANSON of Wilmington, N. C., introduces a current of superheated steam and air into the retort and hastens the removal of the vapors by the use of a suction fan. (1,330,632; assigned to the Pine Nene Products Co.; Feb. 10, 1920.)

Plates for Electrolytic Lightning Arresters.—This invention relates to a method for the preliminary treatment of plates which are to be used in electrolytic lightning arresters, with a view to increasing the breakdown voltage. The process, as described by JOHN COULSON of Wilkinsburg, Pa., may be applied to aluminum, tantalum, platinum or magnesium, but is ordinarily used with the first of these. Aluminum plates are dipped in 1 per cent HF, then in 5 to 10 per cent HCl, and finally in 5 to 10 per cent HNO_3. The acid treatment accomplishes much more than a mere surface cleansing or etching, and appears to penetrate to a considerable distance beneath the surface of the plates. In fact, in the case of thin plates, the acid appears to entirely permeate them, and to completely remove the traces of impurities which are present. This is evident since the acid treatment entirely prevents the formation of blisters which appear when untreated plates are subjected to heat, and which result from the presence of impurities in the interior of the plates. The electrical characteristics of plates pickled in the foregoing manner are found to be materially altered, their admittance being greatly increased as well as their ability to resist high voltages. After the formation of the asymmetric conducting film the plates are preferably heat-treated at 500 to 600 deg. C. for 2 to 3 hr. This increases the breakdown voltage about 25 per cent. (1,330,581; assigned to Westinghouse Electric & Manufacturing Co.; Feb. 10, 1920.)

Manufacture of Bleaching Powder.—Chlorine and lime are passed counter-currently through a rotating horizontal cylinder provided with lugs on the interior so that the mass is mixed and prevented from sticking to the walls. The exterior of the cylinder is cooled by a stream of water in order to overcome the heat of reaction. (1,330,495; ALFRED RUDGE of Gateshead, England; Feb. 10, 1920.)

Anhydrous Metallic Chlorides.—The anhydrous chlorides of aluminum, magnesium and the cerium groups of rare earth metals may be prepared by passing a mixture of chlorine and producer gas (substantially free from hydrogen) over the heated oxide, hydroxide or oxalate of the metal in question. (1,331,257; WILLIAM HEAP of Stockport and EDGAR NEWBERG of Manchester, England; Feb. 17, 1920.)

Recovering Nitrogen Oxides.—Two methods for the recovery of nitrogen oxides from mixtures with air are described by PHILIPPE A. GUYE of Geneva, Switzerland. The gases may be cooled below —20 deg. C. and absorbed in a solvent such as CCl_4 containing C_2Cl_6 or CBr_4. Or, the oxidation of the nitric oxide may be so regulated that a mixture of N_2O_3 and NO_2 is obtained. Upon cooling the oxides below —80 deg. C., a liquid is obtained which is essentially a solution of nitrogen peroxide in nitrous anhydride. If the oxidation is carried to such an extent that only NO_2 is present, this solidifies upon cooling and tends to clog the condensing coils. (1,331,104 and 1,331,105; Feb. 17, 1920.)

Lead Plating.—With the aid of a certain flux, lead plating of iron or steel sheets or other articles may be accomplished in a manner similar to galvanizing. The flux used by ROBERT J. SHOEMAKER of Milwaukee, Wis., consists of 80 per cent zinc chloride, 15 per cent sodium chloride and 5 per cent tin chloride. By means of a frame, a considerable amount of the flux is maintained on the surface of the molten metal at the point at which the work enters. A thin layer of flux covers the rest of the bath. An alloy of 85 per cent lead, 10 per cent antimony and 5 per cent tin is recommended for the production of an adherent uniform coating, free from pinholes. (1,330,399; Feb. 10, 1920.)

Ammonium Nitrate.—The mixture of nitrogen oxides produced by the catalytic oxidation of ammonia is, as a rule, absorbed in water in the presence of oxygen to form a solution of nitric acid. For the production of ammonium nitrate, this acid solution is neutralized with ammonia, giving a dilute solution of NH_4NO_3 which must be concentrated and crystallized. Losses occur in the absorption tower, during neutralization and during evaporation. JAMES R. PARTINGTON, GEORGE J. JONES and THOMAS K. BROWNSON of London, England, have developed a direct neutralization process yielding dry ammonium nitrate. The nitrous gases are cooled to remove the excess of water formed during the catalytic oxidation:

$$4NH_3 + 5O_2 = 4NO + 6H_2O$$

and are then mixed with sufficient air or oxygen to convert the nitric oxide to nitrogen dioxide:

$$2NO + O_2 = 2NO_2$$

This gas is now mixed with ammonia, air and water vapor in the proportions indicated by the equation:

$$4NH_3 + 2H_2O + 4NO_2 + O_2 = 4NH_4NO_3$$

By careful regulation, the ammonium nitrate is obtained as a fine, dry powder which is collected by passing through chambers containing baffle plates. It is evident that nitrous gases from other sources such as the denitration of spent acid may also be used in this process. (1,330,136; Feb. 10, 1920.)

Chromium Sulphate.—The chromium sulphate used in the leather industry is usually prepared from chromate or bichromate by reducing, precipitating the hydroxide, filtering, washing and dissolving the hydroxide in sulphuric acid. FRANK M. MOONEY of Montreal, Que., claims that the following method gives a product which is free from reducing agents which have a harmful effect upon the gelatine in the hide.

$$Na_2Cr_2O_7 + H_2SO_4 = Na_2SO_4 + 2CrO_3 + H_2O \quad (1)$$

$$2CrO_3 + Na_2S_2O_3 = Na_2SO_4 + Cr_2O_3 + SO_2 \quad (2)$$

$$Cr_2O_3 + 3H_2SO_4 = Cr_2(SO_4)_3 + 3H_2O \quad (3)$$

Reaction (2) is not complete unless the solution is boiled to expel the sulphur dioxide. The precipitate of chromic oxide is washed thoroughly and then boiled with sulphuric acid to form the sulphate. (1,330,131; Feb. 10, 1920.)

Industrial Excursions of the A. C. S. St. Louis Meeting

THE entertainment committee of the St. Louis Section of the American Chemical Society more than amply provided an opportunity to get better acquainted with St. Louis for those who had come to the fifty-ninth meeting of the society. Automobile tours made it possible for the visitors to see the parks, Art Museum, Washington University and the Missouri Botanical Garden, as well as several of the chemical plants, of which we give some descriptive notes as follows:

The Laclede-Christy Clay Products Plant

On Thursday afternoon, April 15, a large party visited the plant of the Laclede-Christy Co., located in the southwestern section of St. Louis. This plant is devoted almost entirely to the production of refractories in all shapes and sizes. There are two shaft mines and one open pit mine located adjacent to the plant proper. The plant is equipped with forty periodic kilns for the burning. The total consumption in clay at this plant is 600 tons per day for refractory purposes and 100 tons for production of tile. Both wet and dry process brick is produced. Clay is crammed directly from the mine to the dry pans and thence into the dry presses and subsequently to the waste heat-drying oven. The period of drying occupies about seventy-two hours and the burning about forty-eight hours. Both cones and pyrometer control are used in regulating the kilns. The wires for pyrometer control are all run into a central dispatching station, where multiple switches permit the operator to read the temperature on each kiln.

A thoroughly equipped ceramic laboratory was installed about twenty years ago and continues in operation under the charge of experienced ceramists. Clays are analyzed and classified. Their texture and other physical characteristics are noted. Furnace gases and slags are analyzed as carefully as the clays have been and their action on the burned clays is recorded. As a result the clay mixtures have been standardized and the uniformity of finished products is thus made certain. Many special refractories are made to meet special furnace conditions.

The wet process is also used for making firebrick and sewer tile. Here the proper mixture of clay is moistened with water and passed through an extrusion press of the vertical type with the clay discharged from the side of the cylinder. It does away with the ordinary laminations so common in the pug mill.

There is also being produced in this plant a Laclede-Christy chain grate stoker for firing boilers. The present capacity on these stokers is one per day but will shortly be increased to two or three per day. The plant is a model of cleanliness and efficient operation.

The National Lead Works

The same members who visited the Laclede-Christy Clay Products Co. were next taken to the National Lead Works, located near the former plant.

The material arrives at this plant in the form of pig lead, which is roasted in furnaces for the production of both red lead and litharge, a large bulk of which is sold to the Electric Storage Battery Co., of Philadelphia, for use in manufacturing battery plates. Located in the same building over the lead furnaces is a complete milling plant which brings the oxides to the proper consistency for both the battery and paint trade. By far the largest amount of lead, however, is used in the manufacture of white lead.

In this process the pigs are put through a stamping machine,which stamps out thin perforated circular plates of metallic lead. These, in turn, are placed in refractory pots, in the bottom of which is a quantity of 2½ per cent solution of acetic acid. The pots are porous so that the acid will percolate through the sides of the vessel in about five and one-half hours. A layer of pots is first set on the floor in a concrete bin covered with several inches of tanbark; other layers are built up until eleven tiers in all have been constructed. The whole is covered with tanbark and a pair of flues is introduced at the top for carrying off the gas. The building in which this is carried on is about 600 ft. long and 200 ft. wide, and an enormous quantity of material is fermenting continuously. This requires a large outlay of capital, as the acetic acid and lead are permitted to ferment with the tanbark over a period of 100 days.

When the fermentation process is completed, the pots are emptied into large conveyor boxes, which are carried to mills operating on the principle of the old-time millstone. The subsequent separation by screen-

EAST ST. LOUIS WORKS, MONSANTO CHEMICAL COMPANY

ILLINOIS GLASS CO., ALTON, ILL.

ing removes the white lead from the unconverted metallic lead and the former is thoroughly milled and ground in oil. The entire milling process is the most important feature of the white lead manufacture. Is is finally loaded in cans and sold under the name of Dutch white lead.

Monsanto Chemical Co.

The East St. Louis plant of the Monsanto Chemical Co. afforded more than a few hours diversion from the strenuous division meetings. The old chamber acid plant was inspected first. A testimonial for steel frame work construction could easily be obtained from a study of the operation of these chambers.

The muriatic acid retorts and tile piping and scrubbers were observed next. Perhaps the only feature found worthy of note here was the method of lining tank cars for shipments of hydrochloric acid. Ordinary saturated tar roofing felt and pitch were being used in alternate plies in somewhat the same fashion as in the construction of a specification roof.

The platinum contact oleum works next excited the curiosity of the visitors. The segment ring type of catalyzers were used with no preheating counter-current arrangements.

Some surprise arose to find a new quarter of a million dollar chamber plant almost ready for operation. The latest improvements, such as rotary sulphur burners, nitric acid weirs, etc., were included in its equipment.

Before leaving the plant, the new installation of Allen-Moore caustic soda-chlorine cells was examined. The general impression obtained from the trip was that continued expansion of the East St. Louis plant is scheduled to follow just as has been the case of its organic sister on the west side of the Mississippi.

The Standard Oil Refinery at Wood River

About 300 took advantage of the excursion to the Wood River plant of the Standard Oil Co. Friday, and subsequently to the plant of the Illinois Glass Co., at Alton, Ill.

A thorough inspection was made of all of the apparatus at the Wood River plant, which is capable of handling about 15,000 bbl. of crude oil per day. This plant produces ready for the market all the lighter distillates, petroleum, coke, paraffine wax ready for candle manufacturers, fuel oil and road oils. The company is building a new plant for the additional production of lubricating oils, as well as a large refrigerating system for use in the paraffine plant.

Very close chemical control is maintained throughout all steps of the processes and in conjunction a research laboratory is operated. One of the striking features of the plant is the fact that a large number of the stills are fired by coal. It is found cheaper to buy Illinois coal at approximately a price of $2 a ton rather than burn up the oils and distillates obtainable from the processes. The plant is equipped throughout with every precaution against fire and explosion, and the stills are so arranged that in case any of the material catches fire the combusion will be confined to a small area.

Crude oil is pumped in by pipe line from the Texas and Oklahoma fields, as well as a considerable quantity arriving by tank car. The systems of storage and tanks and stills cover about 1,500 acres of ground.

Illinois Glass Co.

On the arrival of the excursion at Alton the members were entertained at lunch by the Illinois Glass Co. and later taken over for a thorough inspection of the plant. This plant covers seventy-five acres of ground and is equipped with ten 300-ton-capacity continuous glass tanks equipped with thirty bottle-blowing machines producing 1,500,000 bottles daily, ranging in capacity from $\frac{1}{8}$ oz. to 12 gal. Three hundred and fifty tons of coal are gasified in producers and oil is consumed to an extent of 20,000 gal. daily. The daily consumption of other raw materials, including sand, lime and soda ash, is 300 tons. A complete box factory with a capacity of 10,000 boxes daily and a corrugated paper products mill with a daily production of twenty-five tons operates in conjunction with the plant.

The machinery is entirely automatic from the time the bottle-blowing machine picks up the glass batch from the revolving glass pot until the finished product is delivered to the packing room. Each automatic bottle-blowing machine consists of a base carried upon wheels supporting a central column, having six or more arms that revolve about this central axis. To each arm is attached a "blank" and blow-mold, and these are the principal features of its mechanism. As the machine revolves and each blank mold passes successively over the tank of molten glass, a valve opens and the glass is drawn into the blank mold by a vacuum process.

Each blank mold holds exactly the quantity of glass needed for making a bottle of given size, and thus the weight of every bottle is accurately measured and uniformity is secured.

After the glass is gathered into the blank mold the machine makes a quarter revolution, during which time the neck is formed. Then the blank mold opens and falls away, exposing the glass, the blow mold then rises and closes around the hot metal, air pressure is applied, and as the machine completes its revolution the glass is forced against the wall of the molds, giving the exact shape of the bottle to be produced.

In using compressed air the pressure is held steady and uniform so that the glass is evenly distributed throughout the bottle. It is this even distribution that

largely gives strength and uniform capacity to bottles made by the automatic process. The finished bottle is delivered automatically into a suitable receptacle, from which it is carried to the annealing oven, where it is tempered before being packed and shipped.

These annealing ovens are from 70 to 80 ft. in length, with floors composed of metal strips so arranged that they are drawn along slowly by large gear wheels driven by electric motor. It requires six to ten hours for a bottle to travel through the annealing oven, and the temperature at the front end, or machine end, where the bottle is first placed, is about 1,100 deg. F. The annealing oven is divided into air chambers, each cooler than the previous one, so that a bottle traveling through has its temperature gradually reduced until it reaches the rear end, where the temperature is practically the same as the outer air.

Missouri glass sands are mined by the company and shipped by rail to Alton. Even to those who have visited many manufacturing plants, the workings of the Illinois Glass Co. appeal as a marvelous mechanical achievement.

Scientific Apparatus Makers Meet

THE second annual convention of the Association of Scientific Apparatus Makers of the United States of America was held in Washington, April 22 and 23, under the chairmanship of C. S. Stoelting.

Apparatus Standardization Criticized

A special committee reported on a resolution with respect to the calibration and certification of apparatus by the National Bureau of Standards. It was emphasized that this work was of great concern, as at the present time much difficulty in getting prompt reports on apparatus tests is causing difficulties in deliveries of calibrated equipment. On request, W. D. Collins of the Bureau of Chemistry, chairman of the American Chemical Society's committee on standardized chemicals and standardized apparatus, discussed the work of his committee. He pointed out that the American Chemical Society has seriously considered establishing its own laboratory to do this calibration work, and suggested the possiblity that the Association of Apparatus Makers and the American Chemical Society might well co-operate to this end.

The very general importance of an official Government certification of calibrated apparatus was emphasized as one of the important reasons why an independent laboratory should not be established. Various means for co-operation with the Bureau of Standards were discussed, including the possibility of stationing men representing the association at the Bureau in order to expedite the work by actual assistance in it. There was evident a general desire on the part of the membership in attendance to have the testing work separated from the research work of the Bureau, in order that the testing work would not suffer through the desire of individuals or the Bureau to concentrate on research. Some such alternative placing the work upon a clean-cut business basis was favored rather than the effort to establish an independent laboratory.

Apparatus Standards Committee Report

J. M. Roberts reported for the committee on apparatus standards. Major N. E. Reasoner of the Medical Corps, U. S. Army, discussed the variety of apparatus which the Army had been compelled to procure during the war period. However, he pointed out that many points in apparatus form were of no consequence to the user except for interchangeability and therefore the user is interested primarily in standards of performance rather than the manufacturing standards under discussion. Dr. W. D. Collins also reported on the work of the American Chemical Society committee on guaranteed reagents and standardized apparatus. He pointed out that no manufacturers were represented on his committee partly because of the thought that other manufacturers might fear to give full information to the committee if a representative of their competitors were on the committee proper. However, it was pointed out that this committee of the Chemical Society would be very glad to co-operate with the committee of apparatus manufacturers.

The basis of determining the number of sizes and styles of apparatus by means of sales records was discussed at length. It was pointed out that this is a good guide in certain ways, but that so long as a multitude of sizes or styles is listed a great many of them will be ordered, although a much smaller number of varities would probably suit everyone just as well. In this connection several apparatus company representatives pointed out that in the future it was their plan to carry in stock all equipment listed in their catalogues and therefore that the number of items listed was to be very greatly reduced in the future.

In the course of this discussion several glassware manufacturers who are not dealers and therefore do not sell to users were represented. The problems which these makers of glassware meet in changing molded ware were particularly emphasized and it was urged that the problems of these persons be carefully taken into account before the Chemical Society or the apparatus makers' association committees reach final conclusions. Interchange of blue-prints or furnishing of blue-prints of each form of apparatus to the committees was suggested as the best way to undertake the work, especially that of the American Chemical Society committee.

The report of the apparatus standardization committee covering certain specifications for beakers, balances, and other apparatus was adopted by the association with the understanding it was not binding upon the membership, but with the recommendation that all members changing their catalogues during the coming year be guided by its recommendations.

Pyrometer Section

The session of the pyrometer section of the Association dealt principally with the matter of pyrometer materials. Considerable progress was reported, but no definite recommendations were reached at these sessions.

College of City of New York to Give Engineering Degrees

The Board of Trustees of the College of the City of New York has authorized the granting of degrees of Chemical, Civil, Electrical, and Mechanical Engineer on the satisfactory completion of a curriculum requiring five years. The announcement of the details of the curricula will shortly be issued. This is one of the steps taken by the College of the City of New York in the direction of closer co-operation between industry and colleges and universities.

Current Events
in the Chemical and Metallurgical Industries

Engineering Conference

The governing boards of four founder engineering societies met in Chicago April 19 and 20 under the auspices of the Western Society of Engineers. These four societies are the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers.

On Monday evening there was a joint engineering society dinner at the La Salle Hotel. At this dinner A. Stuart Baldwin, past president of the Western Society of Engineers, was toastmaster. Speakers were Arthur C. Davis, president of the American Society of Civil Engineers; Arthur Fletcher, representing the American Institute of Mining and Metallurgical Engineers; Fred J. Miller, president of the American Society of Mechanical Engineers, and Calvert Townley, president of the Electrical Engineers.

The purpose of this meeting was to form plans for better co-operation between the national societies in giving service to the public and securing proper publicity for the professions in general. The Western Society of Engineers presented plans as to how this may be brought about in Chicago, and they are now being considered by the various societies.

The Chicago Chemists' Club

The first get-together meeting of the Chicago Chemists' Club was held as an informal dinner in the quarters at the City Club building on the evening of April 21 with about sixty members in attendance. W. Lee Lewis of Northwestern University delivered a talk on gas warfare redolent with the fumes of butyl mercaptan and other interesting odors. He called attention to the early history of conflict by the use of poisons, commencing with the snake, skunk, et cetera, in animal life and continuing through the savage races to the more recent inauguration into modern warfare by the Germans. Statistics were presented to the effect that only 2 per cent of the casualties die in gas attacks while 24 per cent are lost under shell fire. Gas warfare is most humane and at the same time most effective. This in spite of the propaganda put forth in the United States and England when the Germans first employed chlorine against the Canadians. The talk was concluded by a plea for the maintenance of our activities in the development of new gases and a protest against the retirement of General Sibert to an inactive position in the Army.

Chicago Section, American Ceramic Society

The Chicago Section of the American Ceramic Society met with the Illinois Clay Manufacturers' Association at the Hotel LaSalle, Chicago, on April 20 and 21. The chief event of the occasion was an informal dinner on Tuesday evening with H. T. Bellamy, chairman of the Chicago Section, presiding. H. P. Matzen, of the Carrier Engineering Corporation, presented a paper on "Humidity Drying." I. E. Hardy made a plea for more scientific methods in the enamel brick industry, and informal addresses were given by other members of the two associations.

During the meetings on Tuesday afternoon the forced draft system of burning was informally discussed, and Prof. E. W. Washburn, of Illinois University, delivered an address on "Some of the Factors Involved in the Drying of Clay Wares." "The Tunnel Kiln" was presented by Conrad Dressler and Prof. Carl B. Harrop; C. W. Parmelee of University of Illinois offered a paper on "The Composition of a Paving Brick as Related to Its Rattler Test." The sentiment of the various members during all the discussion called for a greater application of science to the problems of the brick industry, and many members spoke in high appreciation of the work being done by the various universities along these lines.

American Foundrymen's Association to Have New Department

At the annual meeting of the American Foundrymen's Association to be held in Columbus, Ohio, Oct. 4 to 8, a new department will be added to the program to be known as the non-ferrous casting section. At the meetings of this section, papers and discussions of interest to the practical brass and aluminum foundrymen will be presented.

It is understood that the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers will hold a meeting in Columbus during the same week and it is proposed to have a joint session of the non-ferrous section of the American Foundrymen's Association and the Institute of Metals Division of the A.I.M.E.

The other sections that will be represented on the program of the American Foundrymen's Association are the gray iron section, the steel foundry section, the malleable iron section, and the industrial relations section, and in conjunction with these meetings will be held the usual exhibit of foundry and machine shop tools, equipment and supplies.

Meeting of Northern Ohio Section American Ceramic Society

The Northern Ohio Section of the American Ceramic Society met recently in Detroit under the direction of Dr. A. F. Gorton, chairman, and Charles H. Stone, Jr., secretary. Twenty-seven members in all attended this meeting.

The various plants in the vicinity of Detroit were visited, including the Jeffery-DeWitt Co., manufacturer of porcelains for the Champion Spark Plug Co., of Toledo, the Detroit Star Grinding Wheel Co., the Ford Motor Co., and the Pewabic Pottery Co. Luncheon was served at the Detroit Athletic Club and in the evening an informal dinner was enjoyed.

Data From Washburn's Testimony

In the course of his recent testimony before the Senate Committee on Agriculture, Frank S. Washburn presented some interesting data on the consumption of nitrate and ammonia nitrogen and on the estimated future production of ammonium sulphate. These figures are given in Tables I, II and III.

TABLE I. DEMAND FOR NITRATE NITROGEN IN UNITED STATES, 1914[1]

	Per Cent
Sodium nitrate used by fertilizer manufacturers	28
Sodium nitrate used by farmers (bought unmixed)	17
Nitric oxide used in manufacture of sulphuric acid	7
Nitric oxide used in fortifying mixed acid	17
Mixed acid for nitration	12
Oxidizing agent in glass manufacture	6
Oxidizing agent in explosives (as $NaNO_3$)	8
C. p. chemicals for miscellaneous chemical uses	5
	100

[1]Total demand equivalent to 540,000 tons $NaNO_3$.

TABLE II. CONSUMPTION OF AMMONIA COMPOUNDS IN UNITED STATES, 1914[1]

	Per Cent
Ammonium sulphate used in mixed fertilizer	55
Anhydrous ammonia for refrigeration	12
Aqua ammonia for refrigeration, soda ash, explosives, etc.	33
	100

[1]Total demand equivalent to 270,000 tons $(NH_4)_2SO_4$.

TABLE III. AMMONIUM SULPHATE PRODUCTION

	Capacity of byproduct ovens		Surplus over anticipated demands	
	Nitrogen Tons	Ammonium Sulphate Tons	Nitrogen Tons	Ammonium Sulphate Tons
1918	95,000	455,000	20,000	100,000
1919	90,000	450,000	10,000	50,000
1920	111,000	555,000	25,000	125,000
1925	142,000*a*	710,000		
1930	170,000*a*	850,000		
	204,000*b*	1,020,000		
	239,000*c*	1,195,000		

a.—Assuming normal increase in pig iron production and that coke required will come from new byproduct ovens.
b.—Assuming one-half of existing beehive ovens to be replaced by byproduct ovens.
c.—Assuming all existing beehive ovens to be replaced by byproduct ovens.

With regard to the cost of water power at Muscle Shoals, Mr. Washburn said:

"They are proposing now to spend $25,000,000 for a 100,000-hp. plant. That is $250 per hp. Let us assume you could use all of it throughout the year and have no losses from idle time. Five per cent on the cost of your power, nothing else, is $12.50 a horsepower year. Yet these gentlemen in making their estimates have referred to $1.69 for power in one case and in another case about three times that amount. It is true that they did not intend to cover the interest when they mentioned those amounts, but to talk about a cost of $1.69 per horsepower year is so misleading that the mind gets to operating on the basis of $1.69 and forgets that the interest alone that this Government has to pay out, in this period of the highest taxation it has ever known, will be $12.50 a year per hp. My estimate of the cost of producing hydroelectric power at Muscle Shoals is as follows:

Administration and labor		$100,000
Maintenance and supply		60,000
Depreciation, obsolescence, insurance and extraordinary repairs:		
Power house, dam and lock		408,900
Equipment		251,500
Contingencies		60,000
Interest, 5 per cent		1,250,000
Steam plant standby:		
Maintenance	$25,000	
Supplies	15,000	
Heat and light	7,500	
		47,500
Entire total		$2,177,900
Cost per kw.-year		$29.00
Cost per hp.-year		21.77
Cost per kw.-hr.		.0033

"The cost is not only prohibitive but here is the crime in that thing:

"About 90 per cent of the cost of that water power is interest and other percentage items that depend upon cost.

"The Government's position is not only to build the Muscle Shoals hydro-electric plant at a time when taxes are the highest and put $25,000,000 into that item alone, but they propose to do it when labor and materials are the highest this country ever has known. That is not the worst of it. They already have a power plant and they will produce the power and produce it at Government expense at no greater cost than their waterpower after they get it."

"Ten Commandments" for Trade

The Canadian Reconstruction Association, which has long been actively associated with the "Made in Canada" campaign, has formulated the following "Ten Commandments for Canadian Trade":

1. *Buy Canadian products.* In doing so you develop the home market, encourage factory expansion, provide employment for new populations, and create bigger and better markets for all kinds of farm produce. New factories, expansion of old factories, greater production, more workers, and better agricultural market mean national progress.

2. *Import only necessities,* and then only if similar Canadian articles or substitutes are not available. With Canadian money at a discount of 10 to 15 per cent, exchange with the United States is costing Canadian consumers between $75,000,000 and $100,000,000 a year.

3. *Produce to the limit in field and factory.* Increased production means new wealth and is essential to the success of any effort to reduce imports and promote export trade.

4. *Co-operate, conserve, specialize, standardize.* These are the means to maximum production of high-quality goods at minimum cost.

5. *Develop export markets.* Foreign business gives stability to trade. It reduces unit costs, benefits domestic consumer, affords employment to factories and workers in times of depression, and corrects adverse exchange by improving the trade balance.

6. *Utilize Canadian services.* Ship by Canadian carriers through Canadian ports. Patronize Canadian railways, Canadian steamships, and Canadian banks. Place insurance in Canadian companies. Employ Canadian architects, engineers, scientists, and other experts. Spend vacations in Canada.

7. *Manufacture raw materials to final stages in Canada.* Hundreds of millions of dollars are lost annually to the Dominion, and especially to Canadian wage earners, by the exportation of raw materials and semi-manufactured products.

8. *Use science for the determination and development of natural resources.* Industrial research will reveal new wealth, improve industrial processes, and help to relieve our economic dependence upon outside sources for fuel, iron, and other essentials.

9. *Make quality the hall mark of Canadian products.* In return for public support of the home market Canadian manufacturers should provide products that compare favorably with imported goods and Canadian workers should recognize good workmanship and maximum production as their standards.

10. *Be fair to capital.* Canadian money should be encouraged to invest at home and foreign capital attracted to promote Canadian industrial expansion.

Langmuir's New Conceptions

Dr. Irving Langmuir in his address before the National Academy of Sciences at Washington, Tuesday evening, April 27, presented an entirely new theory on the structure of matter. Explaining that his conclusions led to a new conception of energy, force, time, space, magnetism and all the general properties of matter, Dr. Langmuir asserted that "space and time have a structure analogous to that of matter."

Heretofore, the speaker said, the usual conception of the relative order of the components of matter has been atoms, electrons, molecules and particles. His observations add a new division, smaller even than the atom, which he has named the "quantel."

It consists of two parts, he said, positive and negative, present everywhere in space, moving in all directions with the velocity of light and capable of passing through matter. They constitute what has heretofore been known as the "ether of space" and cause all of the phenomena of light, electricity, mass and energy.

"The structure of everything that is" can be built up out of his conception of the quantel, Dr. Langmuir said. The theory explains all of the mysterious relationships heretofore known to exist between spectral lines, he asserted, predicting that it would lead to the discovery of many new relationships.

Chandler Medal Presented to Willis Rodney Whitney

On Tuesday evening, April 27, Dr. Willis R. Whitney gave an address entitled "The Littlest Things of Chemistry" to an attentive and eager audience, all of whom had braved an unusually cold April shower and many of whom drew "standing room only" tickets, that they might see the first presentation of the Chandler Medal since the entrance of the United States into the World War. Could Dr. Whitney have guessed that his associate, Dr. Langmuir, was going to launch quantels down in Washington one hour before his own address, he would probably have not used either the superlative, comparative or picturesque and just called his address: "Some Real Dope on Electrons." The interpretation of the theory that has been built up around this conception of matter affords more than a fascinating pastime. Dr. Whitney justified his belief in the electron theory of matter by showing that he actually makes use of it in his research. The argon rectifier and many other electrical devices are based on phenomena that can only be understood on the electron basis. No attempt will be made to give the details of the address, as it does not lend itself well to abstraction and will be published in full in the June issue of the *Journal of Industrial and Engineering Chemistry*.

Address

After stating that he had never heard so many ideas on chemistry expressed in a single hour, Dr. Chandler presented the medal with the following remarks:

"It is my privilege to present to Dr. Willis Rodney Whitney the Chandler Medal. I appear as the representative of the more than 500 of my old pupils and other friends who in 1910 established this foundation in honor of their old professor. One of these founders graduated as early as 1847, and several others during the succeeding years prior to 1864, when I began with Profs. Egleston and Vinton to teach in the newly founded School of Mines.

"I was deeply gratified when I learned from Prof. McKee that the distinguished Dr. Whitney had consented to deliver the annual lecture. The name is dear to me, and suggests a possible blood relationship between us. My mother was a Miss Whitney of Boston.

Academic Record

"Dr. Whitney was born at Jamestown, N. Y., on Aug. 22, 1868. He graduated at the Massachusetts Institute of Technology in 1890, receiving the degree of S.B. In 1896 he received the degree of Ph.D. at Leipzig. He has been most successful as a teacher of chemistry, having filled the following positions at the Institute of Technology:

1890-1892—Assistant instructor in sanitary chemistry.
1892-1894—Instructor in sanitary chemistry.
1898-1901—Instructor in theoretical chemistry and proximate analysis.
1901-1904—Assistant professor in theoretical chemistry.
1904-1908—Non-resident associate professor of theoretical chemistry.
1908—Non-resident professor of chemical research.

Research Experience

"Since 1900 Dr. Whitney has been the director of the research laboratory of the General Electric Co. at Schenectady, and recently during the war has been a member of the Naval Consulting Board and director of research work at Washington. Words and time fail me to give you any adequate idea of the number, variety and importance of the researches which have been successfully conducted by him and his willing assistants and associates during the past twenty years. Some idea of the magnitude of his activities can be realized from the fact that he has developed the research laboratory at Schenectady from its inception till now he has the direction of more than 150 persons working with him.

"It would require a series of lectures to lay before you an adequate account of the various important results which have been developed under Dr. Whitney's direction. The first radical improvement in the carbon incandescent filament since Edison first produced it was due to Dr. Whitney's personal work. The 'Gem' lamp which he developed with its 'metallized' filament, embodying a new form of carbon, gave 25 per cent more light with the same wattage than the standard carbon filament lamp. Still greater improvements resulted in his laboratory when the drawn wire of tungten gave us the 'tungsten lamp,' then the gas-filled half-watt lamp. Then in arc lighting the laboratory developed the magnetic electrodes, and produced the most successful arc lamp of today.

"Did time warrant, I would gladly tell you about numerous other wonderful discoveries and inventions in the practise of the industrial arts which Dr. Whitney suggested and inspired in his twenty years of research work, and also remind you of the numerous scientific papers he has published in the journals.

The Presentation

"Now, Dr. Whitney, permit me to present to you, as representative of the president and trustees of Columbia University and the more than 500 alumni and friends who established this foundation in 1910, the Chandler Medal, in recognition of your wonderful and successful labors in the application of physics and chemistry to the industries of this country."

New International Chamber of Commerce

The new International Chamber of Commerce, projected at the International Trade Conference at Atlantic City last October, will be formally organized, it is announced by the Chamber of Commerce of the United States, at Paris during the week of June 21. Invitations have been sent out by the American group of the International Organization Committee to business and industrial associations, asking them to name delegates to participate in the organization meeting. About one hundred delegates from the United States are expected to attend.

The International Organization Committee, which was provided for at the International Trade Conference, is to meet at Paris in advance of the general organization meeting, which will be held in June, to prepare and report a plan of permanent organization, the basis of which was drafted and approved at the International Trade Conference. Plans will be presented by the organization committee for a strong and active international chamber. Steps will be taken for the creation of a permanent international headquarters; officers will be elected, and the work of the chamber will actually be started.

The International Chamber succeeds the old International Congress of Chambers of Commerce, which ceased to function with the outbreak of the World War in 1914.

Aims of the Organization

The specific aims of the organization as outlined by the committee on organization are:

To create a permanent international headquarters to centralize all data concerning economic subjects and social conditions, the facts relating to the respective needs, present production, and future possibilities of each country; to act as an instrument of co-ordination which will suggest trade regulations and legislative measures to facilitate and encourage the development of economic commerce; to inform public opinion, through the publication of facts, with regard to business conditions, and through the dissemination of views of technical experts and business men; to put at the disposal of all official organizations the reports and conclusions prepared by these experts and business men.

Constitution of the Chamber

The committee on permanent organization of the International Trade Conference agreed tentatively that the constitution of the new chamber should provide, among other things, for: A board of directors composed of two members selected by each nation; an international headquarters, with one representative of each nation attached to it, assisted by technical experts, all to be under direction of a general secretary; a corresponding bureau in each country; membership to consist of chambers of commerce, commercial organizations, banking and similar associations, firms, corporations and individuals holding associate but not voting membership; meetings of the membership every two years; a system of referenda to be issued during the interval between the biennial meetings of the members.

Other Objects of the Association

Other objects of the association are: To make import and export trade easier; to remove international friction, much of which begins with commercial differences; to safeguard international trade against waste and fraud; to increase the total production of the world, and make the product available to the people of the world; to standardize international documents, practices, and laws affecting commercial intercourse; to increase mutual profitableness of international transactions; to cultivate personal acquaintanceship among business men and bankers of the different nations of the world, and in this manner lessen international prejudices and misunderstandings.

At the first meeting in June only the five countries participating in the International Trade Conference—the United States, Belgium, Great Britain, France, and Italy—will be represented. Later, business organizations in the other principal countries of the world will be taken into membership.

The Short Course in Ceramics at Illinois University

The two weeks' course in clay working recently closed at the State University, Champaign, Ill., was attended by thirty-five students, ranging from the younger men of the industry to prominent executives of the corporations. Work had been carefully planned by the faculty so that an extremely large mass of detail was presented in the short time allowed. In addition to Dr. E. W. Washburn's immediate staff, other members of the university organization who are specialists in lines relating to the clay business assisted with the instruction. E. W. Tillotson, of the Mellon Institute at Pittsburgh, conducted a course in glass manufacture. A. V. Bleininger, U. S. Bureau of Standards, Washington, D. C., lectured on refractories and burning operations.

This effort on the part of an enthusiastic educational organization makes for definite progress in bringing even the most humble clay worker to a realization of the opportunity for increased profits through the adaptation of scientific methods in manufacture of clay wares. The methods of procedure as outlined for use in studying the work in any particular case were so simple that the non-scientific producer would find them easily adaptable.

Aside from the many data carried away by the students there was an added inspiration to higher things for the ceramic art instilled by the earnest lecturers of the course. One student had attended the school for three successive times simply for the enthusiastic impulse he received for the work of the months following.

The faculty gave a smoker at the Beta Theta Pi house for the students of the short course, with invitations to the upper classmen of the regular ceramic engineering courses. Speeches of warm appreciation for the work done by the faculty were made by those in attendance.

Electrochemical Colloquium

The Electrochemical Colloquium for research men in New York and vicinity is being held at 7.45 p.m. on the second and fourth Mondays of each month, in Room 301, Mines Building, Columbia University. A theoretical paper and an industrial paper are reviewed and discussed each time. The Colloquium is a democratic effort by men of varying grades of distinction to keep abreast of the important electrochemical researches of the present day, both in the United States and abroad. All who are interested are invited to participate.

The Vocational School of the C. W. S.

Throughout the U. S. Army training schools for recruits have been organized in fulfillment of the slogan "Enlist and learn!" The Edgewood Arsenal has become headquarters for the Chemical Warfare Service, and here are gathered the recruits, of whom about 1,250 have enlisted since the beginning of the year. These are raw recruits and they have the option to enter the vocational school or not, and the choice of subjects offered for study. This extra training consists in three hours' daily school work five days a week for eleven months a year. Dr. Allen Rogers of Pratt Institute, Brooklyn, is the educational director with rank of "consulting expert" in connection with the War Plans Division operating under a special appropriation by Congress. Other teachers are in the Civil Service. The courses already established are, 1, Electricity; 2, Automobile Mechanics; 3, Machine Shop Practice; 4, Printing; 5, Commercial Course; 6, Grade Work (for illiterates and those who have not completed a grammar school course), and 7, Chemistry.

The vocational training schools have proved a veritable life-saver for the Army, in that the young men of from twenty to twenty-five years of age who enlist are generally a fine lot of fellows. They are ambitious and want to prepare themselves for a good career. Present enlistments in the C. W. S. are for only one year, but it is hoped that this will soon be changed to a three years' term, and thus give the authorities a chance to provide strong courses.

The old barracks are now used for classrooms, and mess halls have been fitted over for shops. One wing is used for automobile mechanics, another for electricity, still another for machine shops, and another for the chemical laboratory. Teachers live in the old Fourth Battalion Headquarters.

About 600 of the 1,250 recruits are taking vocational courses at the present time.

The Courses Provided

The courses in detail are:

Electrical Department. Recruits are taught wiring, etc., together with enough of the principles of electricity to make them journeyman electricians.

Automobile Mechanics. The first rush was for this course because it was thought to be a chauffeur school, and that it would provide opportunities for joy rides. Later on the less thoughtful applicants dropped out. The men are taught assembling and repair work, with driving as a later accomplishment. The shops are but partly equipped with six or eight cars at present, but about thirty cars in all are expected.

Machine Shop Practice. This includes bench work, lathe and general tool work to fit them to be machinists.

Printing. A regular apprentice course.

Commercial Course. Includes accounting, stenography, typewriting and general business.

Grade Work. This provides for illiterates who are learning to read and write. It teaches English to the few foreigners (mostly Italians) who do not speak the language, and it provides a course in citizenship.

Chemistry. This trains men to work as laboratory assistants and to engage in chemical factory work.

The Chemical Warfare Service needs men not only trained to throw bombs, but also those who can repair and drive trucks, electricians for the electrical equipment, men competent as mechanics for machine shop work, men to help in the laboratories, clerks in the offices and printers for the confidential circulars which in practice are frequently distributed. Later on carpentry and plumbing will be added.

There are now over 100 vocational schools in the Army, counting this of the C. W. S. as one. During the coming summer it is planned to organize a month's camp for teachers only, for conference and for the purpose of improving the system of the educational work.

Personal

Major Earl J. Atkinson has been assigned to the command of Edgewood Arsenal. Major Atkinson organized and commanded the first gas regiment in France. He has been serving as engineer instructor at Camp Benning.

M. W. Bray and J. A. Staidl have recently joined the staff of the Forest Products Laboratory. Their work will consist in a study of analytical methods for wood and wood pulp.

Dr. F. G. Cottrell, chief metallurgist of the U. S. Bureau of Mines, will be the recipient of the Willard Gibbs Medal for this year at the May meeting of the Chicago Section of the American Chemical Society, May 21, 1920.

Spencer A. Colville, formerly with the New Amsterdam Gas Co., has been appointed as associate gas engineer of the Bureau of Standards. The Bureau of Standards and the American Gas Association have completed arrangements and secured the aproval of the American Engineering Standards Committee, to be joint sponsors in preparation of the proposed national gas safety code which was partially developed by the Bureau of Standards several years ago, but laid aside because of war work of the bureau. He will assist in these investigations, under the direction of Dr. E. B. Rosa, chief physicist of the bureau, and W. M. Berry, in charge of the Gas Engineering Section.

Prof. C. H. Desch, who has been appointed to the chair of metallurgy in the University of Sheffield (England), was presented by the instructors and students of the evening classes of the Royal Technical College, Glasgow, with a suit case, to mark his departure from the college.

Assistant Professor J. W. E. Glattfeld returned to the University of Chicago on April 1. For three months he has been making researches at the Desert Laboratory of the Carnegie Institution, Tucson, Ariz.

E. J. Mehren, editor of *Engineering News-Record*, has sailed for Europe to study conditions in England, France and Germany and will be abroad until the latter part of August.

H. F. J. Porter will give an illustrated lecture at the Engineers' Club, New York City, May 5. His topics will be "Cornelius Henry Delamater, the Business Man" and "Captain John Ericsson, the Engineer."

Carleton W. Reade, formerly chief chemist for the Delta Chemical Co., Wells, Mich., is now chemist for the Marinette & Menominee Paper Co., Marinette, Wis.

William Kent Shepard, assistant professor of mechanical engineering, Mason Laboratory, Yale University, will take a position about the middle of June with The Barrett Co. at Edgewater, N. J., as head of the division of engineering research.

C. G. Stupp is now assistant chief chemist of the research department of The Barrett Co. at Edgewater, N. J.

The officers of the Association of Scientific Apparatus Makers elected for the coming year were as follows: President, M. E. Leeds; vice-president, H. N. Ott; secretary-treasurer, J. M. Roberts; members of the board of directors, C. M. Stoelting, Mr. Evans, Walter Eimer and L. G. Wilson.

Obituary

GEORGE W. KETTER, who was in charge of electrical installations for the Electric Furnace Construction Co., Philadelphia, died at Claremont, N. H., on April 22, after a short attack of pneumonia.

ELI HILLES LARKIN died at St. Louis, April 16, 1920, in his eighty-first year. Mr. Larkin received his early education in the schools of St. Louis and completed his professional education as a chemist in Germany. With the late Henry V. Scheffer, he founded the co-partnership of Larkin & Scheffer, manufacturing chemists, which later became the Larkin & Scheffer Chemical Co., a corporation, and continued in business in St. Louis until 1911. The firm of Larkin & Scheffer originated the commercial manufacture of liquid anhydrous ammonia in 1879. Mr. Larkin designed the first anhydrous ammonia shipping cylinder, which, improved and perfected, has made possible the operation of isolated ammonia type ice-making and refrigerating plants throughout the world. In 1890 the ammonia business of the Larkin & Scheffer Chemical Co. was acquired by the National Ammonia Co., and until his death Mr. Larkin was a director of that company and technical superintendent of its St. Louis factory. Mr. Larkin was a bachelor, a studious devotee of the science of chemistry and a successful developer of methods for the commercial manufacture of many chemical products. His conspicuous characteristics were a quiet modesty and generous practical charity and philanthropy. His practice was to discover worthy objects of charity and deserving philanthropy and promptly and directly to relieve the one and aid the other. His numerous benefactions were as a rule anonymously bestowed. In his will he bequeathed about $200,000 to various religious and charitable institutions, and in addition he provided liberally for the David Ranken, Jr., School of Mechanical Trades. The "Larkin Foundation," established in the Ranken School of Mechanical Trades, provides for instruction in power plant operation, refrigerating, heating, for lecture courses in technical subjects, and for financial assistance to desirable students.

OLIVER SHEPPARD PICHER, president of the Eagle-Picher Lead Co., died after a short illness of pneumonia, at his home in Winnetka, Ill., on Monday, April 26. Few, even of his business associates, knew of his illness, and his death came to all as a terrific shock. He was a man of unusual vigor, great ability and an exceptionally winning personality, and had built up an organization characterized by a spirit of marked unity of purpose and personal loyalty on the part of each individual, so that every man in the company feels his death as a personal loss. He was an accountant, a metallurgist, a mining engineer, a chemist, a manufacturer and a financier. He was born at Springfield, Mo., but spent his boyhood and youth in California. He was a graduate of Leland Stanford University and Columbia Law School. After finishing his law course he spent three years in the office of the Hon. Elihu Root of New York. Later he went to Joplin, Mo., where his father, Judge O. H. Picher, was president of the Picher Lead Co., with the intention of practicing law there, but soon became interested in manufacturing and abandoned the law for business. In 1906 he became secretary of the Picher Lead Co., a position which he held for three years, until he was elected president to succeed his father, who had retired and gone to live in California. In 1916 the Eagle White Lead Co. and the Picher Lead Co. were merged into the Eagle-Picher Lead Co., and Mr. Picher became president of the consolidated companies, a position which he filled with great brilliancy and success until his death. In 1904 he married Emily Stanton, and had four children, two sons and two daughters, all living. He was director and chairman of the finance committee of the American Zinc Institute. He was a member of the Society of Colonial Wars, Sons of the Revolution, and Columbia Chapter of Alpha Delta Phi.

Current Market Reports

The Non-Ferrous Metal Market

New York, May 3, 1920.—The copper market is strengthening and better business is expected next week. The lead and zinc markets are dull, and prices have declined slightly since last week. Tin is holding its own, 61¼c. being quoted up to April-May, 61c. up to June-July. The freight congestion keeps the market quiet.

	Cents per Lb.
Copper, electrolytic	18.50
Aluminum, 98 to 99 per cent.	32@33
Antimony, wholesale lots	10.00@10.50

The Iron and Steel Market

Pittsburgh, Pa., April 30, 1920.

Transportation conditions, as affected by the rail strike, may have improved materially, but the iron and steel industry itself feels little improvement. On the whole the industry is as much hampered as it has been at any time since the strike started about three weeks ago. While there is some increase in the movement of material, that is largely if not wholly offset by the exhaustion of stocks, particularly of coke at blast furnaces, and by the accumulation of finished products at steel mills.

The Southern and Eastern Districts are scarcely affected, but the iron and steel industry of the Central West has its main arteries of communication, both between parts of the industry and with customers, almost completely clogged. The movement of Connellsville coke has been about one-half the normal, and the movement that occurs is chiefly in solid trainloads, which can be got through only to certain points, chiefly to the lower Monongahela valley, while a few trainloads have gone to the Mahoning and Shenango valleys. There is fairly complete communication with Buffalo. As to the byproduct coke plants, those at Cleveland are doing poorly, while the Lorain plant is running almost full, the Youngstown plants are practically idle and the Benwood, W. Va., plant is operating.

Considering the iron and steel industry as a whole, production of pig iron and finished steel is in the neighborhood of 80 per cent of normal, while shipments of finished steel are hardly much more than 60 per cent of normal.

The iron and steel markets are extremely apathetic. There is a large collection of discouraging factors—discouraging alike to buyers and sellers. Money conditions are, of course, altogether unsatisfactory, with loans for commercial purposes difficult to obtain and with investors generally unwilling to engage in new projects. The outlook as to the willingness of labor to function has been growing poorer again. Strikes are threatened in various cities of machinists, molders and members of other crafts, and even the iron and steel industry itself is again the seat of considerable unrest.

Steel prices in general remain as formerly, the policy of nearly all the independents being to hold to their various prices, which represent premiums for delivery, it being the delivery that varies rather than the price.

Occasional exceptions to this general principle are now noticed, in that in a few special cases in the past week large independent mills have sold merchant bars and structural shapes at the Steel Corporation or Industrial Board prices, 2.35c. for bars and 2.45c. for shapes. The same mills, however, continue to quote their former prices on ordinary business, 2.90c. to 3c. on bars and 3c. to 3.10c. on shapes.

Pig Iron

It is not clearly established whether the production or the consumption of merchant pig iron is curtailed the more by the rail strike, but if the curtailment in production was the greater early in the strike it is likely that with the strike's prolongation the curtailment in consumption will prove the greater. This trend arises from the fact that coke is being got through in solid trainloads to merchant furnaces in some instances, while the distribution of pig iron is very difficult and foundries are running out of stocks, either of pig iron or of coke. Pig iron stocks in consumers' hands are not large, as deliveries of late have been chiefly of iron bought after the pig iron advance was well under way. There is no weakness apparent in pig iron prices, however, but rather the reverse. A technical advance over the market of a few weeks ago is recorded, in that the only quotable market now is the prompt market, there being no interest whatever in second half, while until recently the second half market was the chief part of the market. At that time the valley market stood at $42 for bessemer, $41.50 for basic and $42 for foundry, but now, on the basis of recent sales for early deliveries the quotable market is: bessemer, $42.50; basic, $43; foundry, $43, f.o.b. valley furnaces, freight to Pittsburgh being $1.40.

Chemical and Allied Industrial Markets

New York, April 30, 1920.

The transportation situation is the direct cause of the present depression in these markets. Prices are exceptionally high, but there is very little business being transacted, on account of there being no available material. Originally the car shortage was the stumbling block and the present nominally lifted freight embargo has practically exhausted spot supplies. Producers are unable to obtain the crude material and have been forced to curtail their production to such an extent that it will be some time before they will be in a position to consider new contracts. Shipment by truck has been attempted in some cases, but for long hauls has failed, as the cost is prohibitive. Quotations as received are invariably prices at the works with no mention of shipment made.

General Chemicals

Acetic anhydride came up from 60@65c. per lb. of last week to 65@75c., with slightly better than the usual business manifested, while *acetic acid*, due to extreme shortage, is listed at $3.50@$4.50 per cwt. for 28 per cent, $6.50@$8 for 56 per cent, and $15.50@$17.50 for 99½ per cent glacial, with the latter figure in all cases the most common. Quotations on *aluminum sulphate*, commercial, are nominal, as there is practically no material to be had. Small sales are reported at 2@3c. per lb., and as high as 3@4c. is being asked for *iron-free* grade. Under the pressure of increasing demand and dwindling supplies, *chloroform* came up from 29@32c. per lb. of last week to 32@38c., this situation also applying to *iodine*, resublimed, previously listed at $4.10@$4.30, but now quoted 35@40c. higher. Producers are unable to meet the demand on *magnesium sulphate*, and a considerable shortage of spot material has placed this item in practically a nominal position, current quotations ranging from $3.50@$4.25 per cwt. for U.S.P. and $3.25@$3.60 on commercial.

The extreme shortage of *bleaching powder* and both grades of *soda ash* has held these materials firm at previous levels; inquiry both foreign and domestic continues very heavy, but little actual business has been reported. *Sulphuric acid* remained firm, with very little material coming into the market. It is reported that even with better transportation facilities manufacturers would not be able to cope with the present heavy demand; 60 deg., tank cars, is quoted at $14@$18, 66 deg. at $22@$35 per ton, depending upon the quantity. No change has occurred in *barium* products; chloride remains nominally quoted at $150@$175 per ton, while nitrate holds firm at 10@12c. per lb.

Coal-Tar Products

Buyers of coal-tar products are not inquiring as heavily as before, probably realizing the crisis this market is facing. Plants are being forced to shut down owing to the lack of raw supplies and the inability to ship whatever material is being turned out. Trucking has been resorted to rather extensively but at a very heavy cost and it is the opinion of many that if conditions do not become easier very soon many of the plants will have to shut down completely.

Naphthalene is the latest to join "the nominally-to-be-had-items-at-this-price," 15c. per lb. being asked for both flake and balls, but they can be obtained at this price only in small quantity with no guaranty regarding shipment. One large producer of this item cleaned up his supply the early part of last week, the old contract price of 8@9½c. per lb. prevailing, and is now out of the market. *H* acid is listed as high as $2.25 per lb. in very small quantities, while *paranitraniline* came up to $1.65 per lb. under pressure of extremely short supplies. *Cresol*, U.S.P., also in the same position, is quoted at 18@19c. per lb., against 16@18c. of the previous report. *Aniline oil* held firm at the former level of 34@45c. per lb., with considerable difficulty in locating supplies; the *salts* are better at 46@50c. than the previous report of 42@48c. per lb. Short supply brought about by recent heavy demand has sent all grades of *cresylic acid* up, 97-99 per cent, straw color, in drums, being $1.10@$1.20, against 95c.@$1.10 of last week; 95-97 per cent, dark, in drums, is $1@$1.05, against last week's price of 85c.@$1, while 50 per cent, first, is listed at 65@75c. per gal., which is 5c. better than previously reported.

Naval Stores

There has been no business heard of in the naval stores market during the week. Shortage in the primary market, coupled with a complete tie-up of coastwise shipping, has effectually paralyzed the New York market. An attempt was made to send material by rail to relieve this stringent condition, but hardly had the cars started rolling when the railroad strike was called, cutting New York completely off from the primary market. The complete output is being diverted to the export trade and some material is being sent inland by rail wherever conditions will permit. Rather than quote prices which have no meaning and which do not represent actual sales, figures have been placed in the table that have been obtained from producers and which it is generally understood will hold upon the arrival of material from the South.

Vegetable Oils

There was very little change in the general conditions of the vegetable oil market during the week, prices being

well maintained except in *linseed*, which fell off slightly in futures, $1.72 per gal. being asked for May-June delivery and $1.62 for July-December. The freight embargo has affected the former rise in *cottonseed*, which is now back at the former levels of 16@17c. per lb. for summer yellow and 21@23c. per lb. for winter yellow, with very little activity exhibited on the part of the buyers.

Miscellaneous Materials

Fluorspar — We are advised that 700 tons of gravel fluorspar has been sold for $25 per net ton, f.o.b. mines, southern Illinois, with no analysis guaranty, contracts reading "Fairview Washed Gravel Fluorspar." Also, 1,250 tons were sold at the same price and same shipping point with an average guaranty of 85 per cent calcium fluoride and not over 6 per cent silica, while a small tonnage was sold at the same point, packed in barrels, with no analysis guaranty, at $37.50 per ton. Producers in this territory are not desirous of accepting contracts for acid grades of fluorspar and have refused to make any quotations on these grades. During the past few weeks the demand has become more active, but a good many of the fluorspar companies are pretty well sold. It is asserted that they are holding a certain portion of their tonnage for an expected increase in price.

Quotations on *graphite* remained unchanged during the week. Mexican amorphous graphite is being sold at $55@$60 per short ton; Korean, 3¾c. per lb.; Madagascar, 9c.; Ceylon, 4¾@16c., according to quality.

Feldspar is still in a nominal position; material is piling up at the mill with no transportation facilities available. The price holds firm at $13.50@$18 per ton.

Chicago, Ill., April 28, 1920.

In any report of existing market conditions, full recognition must be given the abnormal state of affairs due to the transportation troubles of the past few weeks. The chemical industry, in common with most others, was affected in two ways, viz.: Inability of manufacturers to ship completed products and the additional time consumed in securing delivery on shipments in transit have materially increased the money burden which the producer has to carry; the great reduction in the volume of receipts in Chicago has produced almost famine conditions in many lines, and prices, when quoted, are either nominal or greatly inflated.

Today's reports are to the effect that the strike is a failure and that the railroads are operating at a high percentage of normal. Even if this is true, it will take a good while to untangle the physical tie-up of cars and longer to get dealers' stocks and users' reserve stocks back on a normal basis. Frequently exhausted stocks mean sky-high prices. Now, however, consumers apparently recognize the futility of attempting to do the impossible, and actual demand is about as light as supply. As a result, prices are stationary. This maintains the market on a sane basis for the resumption of trading when traffic begins to move. What few fluctuations have been noted are in an upward direction.

Heavy Chemicals

The alkali products continue to lead in demand and, while current quotations are nominal, there is no doubt that this line is getting stiffer every day. With makers all booked to capacity for months ahead and with local stocks exhausted, further advances seem probable. It being distinctly a sellers' market, quotations are above those of two weeks ago. *Caustic soda* is going on contract for future delivery at 6½@7c. in cars f.o.b. works. Producers report output hardly sufficient to cover contracts, so spots will be scarce and high for some time. *Soda ash* is nominally quoted at from 3¾@4½c., average being about $3.85 per cwt. Some few small local transactions were recorded at about 4¼c. per lb. Production of *bleaching powder* seems less than market requirements, drums are hard to get and transportation tied up. Current quotation for carloads at factory is 4@4½c. per lb. The same applies to *sal soda*, on which quotations are heard ranging from $1.35 per cwt., f.o.b. factory, to $1.60 per cwt. out of depleted stocks.

The market on various grades of *alcohol* goes through the motions of making quotations. There being practically no goods, they mean but little. *Ethyl* grade is quoted at $4.85@$5.50 per gal. for delivery "when possible," and current actual transactions range all the way from $6 to $8. The quotation on *methyl* remains unchanged at $3 per gal. for 190 proof. The same is true of *denatured* at $1 per gal. There is no definite market for *formaldehyde*, each sale being the subject of negotiation. Only small lots are changing hands, transactions being in the neighborhood of 65c. per lb.

Previously noted interest in *glycerine* continued, 26c. per lb. being current on c.p. grade. *Aqua ammonia*, held firm by producers at 8¼c. per lb., has been run up in spot transactions to above 10c. in some cases. This high price does not seem justifiable. *Sal ammoniac*, unchanged at 16c. per lb. for white granulated, remains in heavy demand. Old contracts for *chlorine* are now being covered by withdrawals. New contracts are offered at 8⅛@8⅜c. per lb., while spots stand at about 8½c. Former firmness in *sodium nitrite* remains, today's price being 26c. per lb.

Acid stocks are practically exhausted. The long-continued weakness of these prices seems to have been corrected by the present shortage, and while no advances of moment are noted, it is believed that when conditions return to normal, existing quotations will be firmly maintained. Transactions in spots are so small as to be negligible, hence no prices are quoted at this time.

Coal-Tar Products

With shortages in crudes, intermediates and derivatives all more acute than ever before, and with all current transactions being influenced by conditions altogether abnormal, it seems useless to attempt to name prices on coal-tar products which are, at best, purely nominal. It is sufficient to say that, with makers of crudes sold up far in advance, the market bids fair to hold firm. The same is true of intermediates, with the added fact that holders of supplies are offering them, and in some cases closing sales, on excessive prices.

Vegetable Oils

The impossibility of securing goods is only equaled by the lack of buying interest, in vegetable oils, a combination which leaves a market almost wholly devoid of interest. With an uncertain future ahead on *linseed oil*, $2.05 per gal. is being quoted in barrels, f.o.b. Chicago, and $1.82½ in cars in bulk. These prices are practically the same as those of four weeks ago. Current quotation on *cottonseed oil* is, for crude, 17c. per gal., prime summer yellow, 18c. per gal., sellers' tanks. *Cocoanut oil* in sellers' tanks, f.o.b. coast, is quoted at 17¼c. for Manila grade, and *corn oil* in tanks for local delivery at 16c. In general, these quotations are nominal, there being but few actual transactions.

Flotation Oils—Naval Stores

Although Savannah price is down to $1.91 per gal. on *turpentine*, the local market has failed to follow, the price being maintained at $2.57 per gal. in barrels, $2.40 in cars. This is justified by the fact that Chicago stocks are completely exhausted and it has not yet been possible to secure local delivery on any of the recent shipments from the South. Jobbers are forced to trace their cars and, upon locating them in Hammond, Gary, East Chicago or wherever they may be resting, send motor trucks to bring the goods on into the city. Thus an enormous addition is put on the cost. It is a condition that may be relieved any day, at which time the price will drop materially. Consumers, aware of the facts, are buying only such supply as is their absolute immediate requirement. There being no supply of flotation oils, hence no trading, nominal quotations show no change from a fortnight ago. The same is true of rosin in the various grades.

Fertilizers

The very great curtailment of operations in the stock yards occasioned by the railroad troubles served to cut off both production and demand. Such quotations as are available are of no value as transactions are practically nil.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	–	$0.65 – $0.75

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 — $1.10
Alpha naphthol, refined	lb.	1.40 — 1.60
Alpha naphthylamine	lb.	.40 — .50
Aniline oil, drums extra	lb.	.34 — .45
Aniline salts	lb.	.46 — .50
Anthracene, 80% in drums (100 lb.)	lb.	.90 — 1.00
Benzaldehyde (f.f.c.)	lb.	2.00 — 2.10
Benzidine, base	lb.	1.25 — 1.35
Benzidine, sulphate	lb.	1.20 — 1.25
Benzoic acid, U. S. P.	lb.	.90 — 1.10
Benzoate of soda, U.S.P.	lb.	.80 — 1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 — .36
Benzol, 90%, in drums (100 lb.)	gal.	.25 — .31
Benzyl chloride, 95-97%, refined	lb.	.35 — .40
Benzyl chloride, tech.	lb.	.25 — .35
Beta naphthol benzoate	lb.	.50 — .65
Beta naphthol, sublimed	lb.	.70 — .90
Beta naphthol, tech.	lb.	.45 — .55
Beta naphthylamine, sublimed	lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 — .19
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.10 — 1.20
Cresylic acid, 95-97%, dark, in drums	gal.	1.00 — 1.05
Cresylic acid, 50%, first quality, drums	gal.	.65 — .75
Dichlorbenzol	lb.	.08 — .10
Diethylaniline	lb.	1.40 — 1.50
Dimethylaniline (nominal)	lb.	—
Dinitrobenzol	lb.	.30 — .37
Dinitroclorbenzol	lb.	.25 — .30
Dinitronaphthaline	lb.	.45 — .55
Dinitrophenol	lb.	.34 — .36
Dinitrotoluol	lb.	.40 — .45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 — .40
Diphenylamine (nominal)	lb.	.55 — .65
H-acid (non inal)	lb.	2.25 — 2.50
Metaphenylenediamine	lb.	1.15 — 1.80
Monochlorbenzol	lb.	.12 — .15
Monoethylaniline	lb.	.70 — 1.85
Naphthaline crushed, in bbls. (250 lb.)	lb.	.15 —
Naphthaline, flake	lb.	.15 —
Naphthaline, balls	lb.	.15 —
Naphthionic acid, crude	lb.	.70 — .85
Nitrobenzol	lb.	.14 — .19
Nitro-naphthaline	lb.	.40 — .50
Nitro-toluol	lb.	.20 — .30
Ortho-amidophenol	lb.	3.75 — 4.25
Ortho-dichlor benzol	lb.	.15 — .20
Orthonitrophenol	lb.	.80 — 1.25
Ortho-nitro-toluol	lb.	.25 — .40
Ortho-toluidine	lb.	.25 — .45
Para-amidophenol, base	lb.	2.50 — 3.50
Para-amidophenol, HCl	lb.	2.50 — 3.25
Para-dichlor-benzol	lb.	.08 — .12
Paranitraniline	lb.	1.65 —
Para-nitro-toluol	lb.	1.55 — 1.60
Paraphenylenediamine	lb.	2.60 — 3.00
Paratoluidine	lb.	2.00 — 2.50
Phthalic anhydride	lb.	.65 — .75
Phenol, U. S. P., drums (about 240 lb.)	lb.	.12 — .25
Pyridin	gal.	.90 — 2.50
Resorcin, technical	lb.	4.25 — 4.50
Resorcin, pure	lb.	5.25 — 6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.50 — .52
Salicylic acid, U. S. P.	lb.	.55 — .60
Salol	lb.	.90 — 1.00

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.25	—	$0.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.25	—	.30
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.38	—	$0.39
Beeswax, refined, light	lb.	.40	—	.41
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1. (nominal)	lb.	.80	—	.88
Carnauba, No. 2, regular (nominal)	lb.	.60	—	.70
Carnauba, No. 3, North Country (nominal) . . †	lb.	.45	—	.46
Japan	lb.	.21	—	.22
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.....	—	.09½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.09¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	—	.11¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.....	—	.13½
Paraffine waxes, refined, 133-135 m.p.	lb.	.14	—	.15
Paraffine waxes, refined, 135-137 m.p.	lb.	.16	—	.16½
Stearic acid, single pressed	lb.	.26	—	.27
Stearic acid, double pressed	lb.	.32	—	.29
Stearic acid, triple pressed	lb.	.32	—	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.38
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref	gal.	.52

*Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl	280 lb.	$16.95	—	$18.75
Rosin E-I	280 lb.	18.75	—	19.00
Rosin K-N	280 lb.	19.00	—	21.00
Rosin W. G.-W. W	280 lb.	20.50	—	21.50
Wood rosin, bbl	280 lb.	15.50	—	18.50
Spirits of turpentine	gal.	.....	—	2.50
Wood turpentine, steam dist	gal.	2.35	—	2.40
Wood turpentine, dest. dist	gal.	.....	—	2.00
Pine tar pitch, bbl	200 lb.	8.40	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	15.00
Retort tar, bbl	500 lb.	15.00	—	15.50
Rosin oil, first run	gal.	.92	—	.95
Rosin oil, second run	gal.	.94	—	.97
Rosin oil, third run	gal.	1.00	—	1.05
Rosin oil, fourth run	gal.	1.10	—	1.15

* (See New York market letter)

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.40½	—	$0.42
Upriver coarse	lb.	.30½	—	.32
Upriver caucho ball	lb.	.32½	—	.33
Plantation—First latex crepe	lb.	.44	—	.45
Ribbed smoked sheets	lb.	.44½	—	....
Brown crepe, thin, clean	lb.	.42	—	....
Amber crepe No. 1	lb.	.40½	—	.41½

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.18½	—	$0.20
Castor oil, AA, in bbls	lb.	.20	—	.23
China wood oil, in bbls	lb.	.24	—	.24½
Cocoanut oil, Ceylon grade, in bbls	lb.	.18½	—	.19½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.20	—	.21
Corn oil, crude, in bbls	lb.	.17¾	—	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.16	—	.17
Cottonseed oil, summer yellow	lb.	.18½	—	.19
Cottonseed oil, winter yellow	lb.	.21	—	.23
Linseed oil, raw, car lots	gal.	1.84	—	...
Linseed oil, raw, tank cars	gal.	1.79	—	...
Linseed oil, boiled, car lots	gal.	1.87	—	...
Olive oil, commercial	gal.	2.75	—	3.00
Palm, Lagos	lb.	.15½	—	.16½
Palm, bright red	lb.	.14½	—	.17½
Palm, Niger	lb.	.14	—	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22	—	.23
Peanut oil, refined, in bbls	lb.	.25	—	.26
Rapeseed oil, refined in bbls	gal.	1.62	—	1.64
Rapeseed oil, blown, in bbls	gal.	1.68	—	1.70
Soya bean oil (Manchurian), in bbls N. Y.	lb.	.17	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.14	—	.14½

WH. FISH

f.o.b. [illegible] pressed Menhaden	gal.	$1.17	—	$1.18
[illegible] bleached Menhaden	gal.	1.20	—	1.22
bleached Menhaden	gal.	1.23	—	1.24
[illegible]haden	gal.	1.34	—	1.36

York market letter)

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$38.00	—	$40.00
Barytes, off color	ton	20.00	—	25.00
Blanc fixe, dry	lb.	.04½	—	.05½

*Nominal

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	$75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	45-50 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	40-45 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	50-55 at Mt. Union, Penn.

Ferro-Alloys

All Prices f.o.b. works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20	—	.21
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21	—	.22
Ferro-manganese, 70-80% Mn	gross ton	200.00	—	250.00
Spiegeleisen, 16-20% Mn	gross ton	60.00	—	65.00
Ferro-molybdenum, per lb. of Mo	lb.	2.25	—	2.75
Ferro-silicon, 50%	gross ton	80.00	—	90.00
Ferro-silicon, 75%	gross ton	150.00	—	200.00
Ferro-silicon, 10-15%	gross ton	60.00	—	65.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	.90	—	1.10
Ferro-uranium, 35-50%, of U	lb.	7.00	—	.....
Ferro-vanadium, 30-40% per lb. of contained V	lb.	6.50	—	7.75

Ores and Semi-finished Products

All Prices f. o. b. Mines

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70	—	$0.85
Chrome ore, 48% and over	unit	1.00	—	1.25
Coke, foundry, f.o.b. ovens	net ton	12.00	—	14.00
Coke, furnace, f.o.b. ovens	net ton	11.00	—	12.00
Petroleum coke, refinery, Atlantic seaboard	net ton	.....	—	14.00
Fluor spar, gravel, f.o.b. mines	net ton	25.00	—	30.00
Manganese ore, 45% Mn and over	unit	.75	—	.85
Manganese ore, chemical (MnO_2)	gross ton	80.00	—	90.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	7.00	—	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50	—	7.50
Uranium oxide, 96%	lb.	2.75	—	3.00
Vanadium pentoxide, 99%	lb.	12.00	—	14.00
Pyrites, foreign, lump	unit	.17	—	.....
Pyrites, foreign, fine	unit	.17	—	.....
Pyrites, domestic, fine	unit	.16	—	.17½
Ilmenite, 52% TiO_2	lb.	.02	—	.....
Rutile, 95% TiO_2	lb.	.11	—	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75	—	3.00
Zircon, washed, iron free	lb.	.10	—	.....
Monazite, per unit of ThO_2	unit	42.00	—	.....

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

SALINAS—The Bd. Educ. plans to build a 2-story high school here. A chemical laboratory will be installed in same. Wyckoff & White, archts.

Connecticut

MIDDLETOWN — Henry Bacon, 101 Park Ave., New York City, archt. and engr., will receive bids until May 23 for the construction of a 2-story chemical laboratory for the Wesleyan University, 374 High St. Estimated cost, $500,000. Noted March 10.

District of Columbia

WASHINGTON—The Bureau of Yards & Docks, Navy Dept., plans to build an aëronautical engine-testing laboratory.

Illinois

CHICAGO—The Columbia Colortype Co. is building a 6-story, 123 x 177-ft. building on the northeast corner of Calumet Ave. and 21st St. Estimated cost, $600,000. R. C. Wieboldt, 1534 West Van Buren St., contractor.

KEWANEE—The Kewanee Boiler Co. has awarded the contract for the construction of plant extensions including new 80 x 1,750-ft. buildings, to the Lackawanna Bridge Co.

Iowa

CUSHING—The city has awarded the contract for the construction of a sewage disposal plant to Ward & Weighton, 516-17 Davidson Bldg., Sioux City, at $10,995.

DANA—The Bd. Educ. will receive bids until May 17 for the construction of a 2-story, 56 x 86-ft. consolidated school building. A chemical laboratory for general work will be installed in same. Estimated cost, $100,000. Guy Meredith, secy. W. E. Hulse & Co., 210 Masonic Temple, Des Moines, archts.

DES MOINES—The Dempster Mfg. & Supply Co., 201 East Court Ave., has awarded the contract for the construction of a 1-story, 120 x 180-ft. foundry and machine shop on East Court Ave., to A. H. Neumann & Co., 519 Hubbell Bldg. Estimated cost, $100,000.

GILMAN—The School Bd. is having preliminary plans prepared for the construction of a 2-story consolidated school. A chemical laboratory will be installed in same. Estimated cost, $100,000. R. J. Paul, pres. Keffer & Jones, 204 Masonic Temple, Des Moines, archts.

GOWRIE—The Bd. Educ. is having preliminary plans prepared for the construction of a 3-story, 65 x 100-ft. school building. A general chemical laboratory will be installed in same. Estimated cost. $125,000. Clarence Strand, secy. Keffer & Jones, 204 Masonic Temple, Des Moines, archts.

MEDIAPOLIS—The Bd. Educ. is having preliminary plans prepared for the construction of a 3-story consolidated school. A chemical laboratory will be installed in same. Estimated cost, $160,000. J. E. Berry, secy. Keffer & Jones, 204 Masonic Temple, Des Moines, archts.

MORNING SUN—The Bd. Educ. will receive bids until May 8 for the construction of a 2-story, 56 x 130-ft. school building. A general chemical laboratory will be installed in same. Estimated cost, $200,000. O. F. Beller, secy. W. E. Hulse & Co., 210 Masonic Temple, Des Moines, archts.

PACKWOOD—N. E. Olliver, secy. of the Bd. Educ., will receive bids until May 7 for the construction of a 2-story, 58 x 99-ft. school building. A general chemical laboratory will be installed in same. Estimated cost, $125,000. W. E. Hulse & Co., 210 Masonic Temple, Des Moines, archts.

YARMOUTH—The Bd. Educ. is having preliminary plans prepared for the construction of a 3-story consolidated school. A chemical laboratory will be installed in same. Estimated cost, $100,000. C. C. Featherby, secy. Keffer & Jones, 204 Masonic Temple, Des Moines, archts.

Kansas

OSAWATOMIE—The Missouri Pacific Ry. plans to build a modern water treating plant, here. Estimated cost, $61,700.

Kentucky

LOUISVILLE—The Stoll Oil Refining Co., 733 River Road, will build a 1-story, 44 x 60-ft. filter house and is in the market for filter house machinery, etc. Work will be done by day labor.

Maryland

BALTIMORE—C. M. Anderson, arch., 324 North Charles St., will soon award the contract for the construction of a 3-story, 61 x 76-ft., addition to tinware enameling and stamping plant for the Natl. Enameling & Stamping Co., Race and Ostend Sts. Estimated cost, $100,000.

CURTIS BAY (Baltimore P.O.)—The Union Acid Wks. have awarded the contract for the construction of a 2-story, 200 x 500-ft. acid plant on Aspin and Railroad Aves., to the Whiting-Turner Constr. Co., Stewart Bldg., Baltimore. Estimated cost, $200,000. Noted Jan. 14.

HAGERSTOWN—The Washington Co. School Comrs., Courthouse, are having plans prepared for the construction of a high school. A chemical laboratory will be installed in same. Estimated cost $150,000. R. E. Staley, 247 South Prospect St., supt. A. J. Klinkhart, 54 West Washington St., archt.

Massachusetts

CAMBRIDGE—The Lever Bros. Co., Portland St., has awarded the contract for the construction of a 6-story, 90 x 190-ft. factory for the manufacture of soaps, to the Stone & Webster Eng. Corps., 147 Milk St., Boston. Estimated cost, $350,000.

CHELSEA—Leon E. Gingras, 156 Marginal St., has awarded the contract for the complete remodeling of tannery building on Marginal St., to Tuck & Gilman, 34 School St., Boston. Estimated cost, $65,000.

HOLYOKE—The Hampden Glazed Paper & Card Co., Riverside, has awarded the contract for the construction of a 2-story manufacturing plant, to the Casper Ranger Constr. Co., 2 Bond St. Noted May 4.

NATICK—The New England Pressed Steel Co. has awarded the contract for the construction of a 1-story, 55 x 85 ft. factory addition, to A. Jensen Co., Sawin St. Estimated cost, $25,000. Noted March 31.

WEST SPRINGFIELD (Springfield P. O.)—McClintock & Craig, engrs., 33 Lyman St., Springfield, will soon award the contract for the construction of a 1-story, 90 x 200-ft. factory for the manufacture of electrical specialties, for the Wico Electric Co., 44 Avon Place. Estimated cost, $75,000. Phelps Brown, pres.

Michigan

MARYSVILLE—The village is having plans prepared for the construction of a semi-permanent water supply system consisting of pumping station, filtration plant, etc. Estimated cost, $200,000. Robert Gordon, engr.

Minnesota

FOREST LAKE—The Bd. Educ. plans to install a chemical laboratory in the new high school here. Foss & Foss, St. Cloud, archts.

JAMESVILLE—The village will receive bids until May 7 for the construction of a sewage disposal plant consisting of an Imhoff tank, etc. R. R. Brown, village recdr.

OLIVIA—The Bd. Educ. is having plans for the construction of a 2-story high school here. A chemical laboratory will be installed in same. Estimated cost, $185,000. W. L. Alban, Endicott Bldg., St. Paul, archt. Terry Schulte Eng. Co., Endicott Bldg., St. Paul, engr. Bonds have been voted for the project.

SACRED HEART — The Independent School Dist. 40 rejected all bids for the construction of a 2-story high school here. A chemical laboratory will be installed in same. W. L. Alban, 347 Endicott Bldg., St. Paul, archt. Terry Schulte Eng. Co., 484 Endicott Bldg., St. Paul, Engr.

Missouri

ST. LOUIS—W. R. Coney & Co., New York City, have purchased the plant of the Mutual Brewery Co. on the northeast corner of Boyle and Duncan Aves., here, and plan to convert same for bleaching and coloring materials.

ST. LOUIS—The Crunden Martin Mfg. Co., 21st and Gratiot Sts., plans to build a 6-story factory building on the southeast corner of 2nd and Cedar Sts. The building will be used to house a manufacturing plant for galvanized enamel ware. Estimated cost, $500,000.

ST. LOUIS—The General Electric Co., Pierce Bldg., is building a plant for the manufacture of electric light bulbs on the corner of Union and Brown Aves. Estimated cost, $300,000.

Nevada

FALLON—The Humboldt Potash Co. plans to construct a large chemical plant, here. The plant will operate on potash from the extensive deposits in the Dixie Valley. The New York Syndicate has secured control of 36,000 acres in the Dixie Valley and plans to build first unit of plant on same.

New Jersey

NEWARK—The Amer. Brake Shoe Co., 30 Church St., New York City, has awarded the contract for the construction of a 1-story foundry on Ave. L between Mary and Paris Sts., to James Stewart, 30 Church St., New York City. Foundry equipment will be installed in same. Estimated cost, $400,000.

New York

BUFFALO—The Amer. Brass Co., Grand and Meadow Sts., Waterbury, Conn., will build a 165 x 650-ft. rolling mill at 446 Military Rd. Estimated cost, $600,000. Work will be done by day labor.

BUFFALO—The Dept. of Pub. Wks. received bids for the delivery of 80,000 lb. of liquid chlorine from the Mathieson Alkali Wks., Inc., 25 West 43rd St., New York City, $5,920; Electric Bleaching Gas Co., 18 East 41st St., New York City, $5,920; Hooker Electrochemical Co., 25 Pine St., New York City, $5,968. Noted April 14.

BUFFALO—The Donner Union Coke Corp., Abbey and Bell Sts., has filed plans to construct a 1-story, 8 x 28 x 31-ft. steel laboratory and a 1-story, 15 x 17 x 26-ft. first aid building. Estimated cost, $10,000.

BUFFALO—The General Drop Forge Co. has awarded the contract for the construction of a 1-story, 60 x 100-ft. forge shop and a 1-story, 100 x 100-ft. heat treating plant, to J. C. Cowper Co., Fidelity Bldg. Estimated cost, $200,000.

GREYCOURT—The Comr. of Correction, Municipal Bldg., will receive bids until May 7 for the furnishing of all labor and material for the construction of a sewage disposal plant for the New York City Women's Farm Colony, here.

JAMAICA—The A. L. Read Co., Jamaica Ave. and 121st St., Richmond Hill, has awarded the contract for the construction of a 2-story, 70 x 125-ft. leather factory, to Barney Ahlers, 110 West 40th St., New York City Estimated cost, $75,000.

LONG ISLAND CITY—The Elcaya Co., 148 Madison Ave., New York City, plans to build a 4-story laboratory on First St. between Reeve and Freeman Aves., here.

LONG ISLAND CITY—S. L. Reily, archt. and engr., 112 West Adams St., Chicago, Ill., will soon award the contract for the construction of a 4-story factory for the manufacture of oil products, for the P. Van Iderstine Construction Co., Greenpoint Ave.

SYRACUSE—The M. L. Oberdorfer Brass Co., 804 East Water St., has awarded the contract for the construction of a brass factory at Messina Springs, to the A. & T. Constr. & Eng. Co., 115 South Salina St. Estimated cost, $500,000. Noted Feb. 25.

North Carolina

CHERRYVILLE—The Cherryville Foundry Wks. has plans prepared for the construction of a foundry for the manufacture of gray iron castings. C. C. Dellinger, prop.

North Dakota

McVILLE—The Council has awarded the contract for furnishing a concrete septic tank, etc., to Gedney & Murphy, Fargo, at $25,877. Noted April 21.

Ohio

CANTON—The Superior Sheet Steel Co. plans to build a 1-story 120 x 500-ft. steel building on Louisville Rd. Estimated cost, $200,000.

CLEVELAND — The city will soon award the contract for the construction of a filtration plant, etc., at Baldwin. Estimated cost, $200,000. A. V. Ruggles, City Hall, engr. Noted March 23.

WARREN—The Warren Iron & Steel Co. is having plans prepared for the construction of a 1-story, 120 x 300-ft. rolling mill. Estimated cost, $150,000. Watson Eng. Co., Hippodrome Bldg., Cleveland, archt. and engr.

Oklahoma

HENRYETTA — C. A. Strecker, Oklahoma City, plans to remodel plant recently purchased here and equip it with the Duwell process for refining gasoline, naphtha and kerosene.

PRYOR—The city voted $35,000 bonds to improve waterworks, including purification plant, etc. V. V. Long & Co., Colcord Bldg., Oklahoma City, engr.

TULSA—The Oklahoma Steel Castings Co. has purchased a 9½-acre site west of Pearl St. and south and east of the Santa Fe R.R. Company's main line and plans to construct a plant on same. The company will manufacture steel castings of either acid or basic steel for the oil industry, etc. Estimated cost, $100,000. Clarence B. Douglas, mgr.

Pennsylvania

JEANETTE—The Amer. Window Glass Co., Farm Bank Bldg., Pittsburgh, is having plans prepared for the construction of a 1-story, 42 x 182-ft. building.

PITTSBURGH—The McKenna Brass & Mfg. Co., 1st and Ross Sts., plans to build a 4-story, 53 x 80-ft. addition to present plant. Estimated cost, $175,000. James T. Steen & Sons, Fulton Bldg., archts.

ROCHESTER—The H. C. Fry Glass Co. has awarded the contract for the construction of a 1-story, 80 x 200-ft. glass factory to the Austin Co., Union Arcade, Pittsburgh. Estimated cost, $110 000.

Rhode Island

PAWTUCKET—The Fales & Jenks Machine Co., 320 Dexter St., has awarded the contract for the construction of a 3-story, 45 x 80-ft. manufacturing building addition on Pine St., to Willmarth Mackillop, Inc., Freeman St. Estimated cost, $50,000.

South Carolina

GREENWOOD—The Bd. Educ. plans to build a 3-story college for women. A chemical laboratory will be installed in same. Estimated cost, $100,000 T. W. Cothran, contg. engr.

Texas

BASTROP—The city will soon receive bids for the construction of a 2-story, 58 x 60-ft. high school. A chemical laboratory will be installed in same. Estimated cost, $30,000. H. F. Kuehne, 824 Littlefield Bldg., Austin, archt.

DALLAS—The Eastland Oil & Refining Co., Security Natl. Bank Bldg., is having plans prepared for the construction of a lubricating unit to oil refinery, including equipment for refining oil and preparing lubricating oil as one of the products. Estimated cost, $350,000. H. P. Williford, 3501 Harvard Ave., engr.

DALLAS—The School Bd. is having plans prepared for the construction of a 3-story high school on Haskell and McKinney Sts. Chemical laboratory equipment will be installed in same. Estimated cost, $250,000. W. B. Ittner, Bd. Educ. Bldg., St. Louis, Mo., archt.

MEMPHIS—The Memphis Cotton Oil Co. will soon receive bids for rebuilding main building which was recently destroyed by fire and installing new machinery in same. Estimated cost, $200,000

MERCEDES—The Independent School Dist. is having plans prepared for the construction of a 1-story, 157 x 217-ft. high school here. A chemical laboratory will be installed in same. Estimated cost, $75,000. H. F. Kuehne, 824 Littlefield Bldg., Austin, archt.

NECESSITY (Caddo P.O.)—The Alamo Refining Co., Eastland, plans to purchase a 5-acre site and build a plant on same. The plant will be built on a unit basis. J. R. Evans, mgr. G. B. Dartoise, chief engr.

West Virginia

CLARKSBURG—The Bd. Educ. will soon award the contract for the construction of a junior high school. A chemical laboratory will be installed in same. J. N. Hess, Empire Bank Bldg., secy.

Wisconsin

KENOSHA—Allen Sons Co., North Main St., is having plans prepared for the construction of a sewage disposal plant. Estimated cost, $50,000. Vaughn & Meyer, Security Bldg., Milwaukee, engrs.

SHEBOYGAN FALLS—C. S. Weisse Tanning Co. will build a 3-story, 84 x 248-ft. tannery on Buffalo St. Estimated cost, $150,000. Work will be done by day labor. Noted April 21.

ST. CROIX FALLS—The Bd. Educ. engaged W. L. Alban, archt., 347 Endicott Bldg., St. Paul, to prepare plans for the construction of a 2-story, 53 x 90-ft. high school, here. A chemical laboratory will be installed in same. Estimated cost, $75,000. F. R. Nash, principal.

Ontario

ELMIRA—The city plans to construct a sewerage system. Septic tanks will probably be installed in same. Estimated cost, $30,000. H. Johnston, Kitchener, engr.

TORONTO—The Barrett Co., 17 Battery Pl., New York City, has awarded the contract for the construction of a roofing factory, to James Stewart, 30 Church St., New York City. Estimated cost, $400,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its sixth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept, 7 to 10 inclusive.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold regular meetings on May 7 and June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY OF REFRIGERATING ENGINEERS will meet in St. Louis May 27 to 29.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18, inclusive.

THE AMERICAN ZINC INSTITUTE will hold its spring meeting May 10 and 11 at the Congress Hotel, Chicago, Ill.

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK announces the following lectures for the spring semester of 1920 to be delivered in the Doremus Lecture Theater: "Chemical Naval Warfare," Friday, May 7, at 4 p.m., Prof. James Kendall, professor of chemistry at Columbia University; "Fighting Fire—Firefoam," Friday, May 14, at 4 p.m., F. A. Epps. chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA plans to hold its annual convention in the Auditorium Theater, Chicago, Ill., May 19, 20 and 21.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect. The autumn meeting of the Iron and Steel Institute (British) will be held at Cardiff, by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE MINE INSPECTORS' INSTITUTE OF AMERICA will hold a meeting at Cleveland, Ohio, July 13, 14 and 15.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 and 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE NEW JERSEY CHEMICAL SOCIETY plans the following: Monday evening, May 10, regular meeting; Saturday afternoon and evening, June 5, at Rutgers College, New Brunswick, N. J., regular meeting and ladies' day.

THE SOCIÉTÉ CHIMIE INDUSTRIELLE will hold a meeting at the Chemists' Club, May 14.

THE SOCIETY OF COTTON PRODUCTS ANALYSTS will hold its eleventh annual conventoin at the Grunewald Hotel, New Orleans, La., May 10 and 11.

THE SOCIETY OF CHEMICAL INDUSTRY, American Section, will hold a meeting, May 21, at the Chemists' Club.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

THE TAYLOR SOCIETY, the national organization for the promotion of scientific management in industry, will hold a meeting May 6, 7 and 8 at Rochester, N. Y., under the auspices of the Industrial Management Council and the Manufacturers' Council of the Rochester Chamber of Commerce.

Industrial Notes

HOLZ & Co., metallurgical engineers and dealers in testing equipment, announce the organization of a filtration department. The new department, under the management of Frank H. Lowenfels, is prepared to supply or prepare specifications for all types of laboratory and plant filtration equipment. In connection with this service, a complete line of Franklin filter paper will be placed on the market.

THE B. F. GOODRICH RUBBER CO. has equipped the grain elevator of the Pennsylvania R.R. at Canton, near Baltimore, with approximately 8½ miles of conveyor belting. This represents the largest single order of belting ever shipped, and it required seven box cars to transport it from Akron to Baltimore. The belting totaled 44,254 ft. and weighed 131 tons. The capacity of one of the 48-in. horizontal carrier belts is 350,000 bushels of grain in a 10-hr. day.

THE MATHIESON ALKALI WORKS, INC., announces that it is handling direct the sales of all its products, and that the executive and general sales offices have been moved from Providence, R. I., to 25 West 43d St., New York City.

THE ST. LOUIS DRUG AND CHEMICAL CLUB has been formed in St. Louis, Mo., with 100 charter members.

The One And T'other

TWO members of the editorial staff were in conference. We shall refer to them as One and T'other. "I don't know whether my reading has been ill-chosen or not," said One, "but somehow I find little in current journals except complaint and grumbling about persons and parties in opposition. The only agreement I find is that everything is going to the devil, and, to prove it, it seems as if any old argument would do. If I look into the *New Republic* it almost appears as if the cats and dogs were upon us because we do not invite the cats and dogs to have their way and rule us, whereas from the *Review* I gather that the great threat of our dissolution is the healing balm of the *New Republic.* That the Hearst papers should stir up hatred and anger is to be expected, for this is their meat and drink; but publications that have heretofore been edited with conscience are charging either President WILSON or Senator LODGE with guilt for all the evils that may come upon us. Have we become a nation of common scolds? Have we no more constructive minds? Were our thinking men killed in the war?

"All this leads me to believe that it is high time for us to take a hitch in our belts; to put an end to unceasing complaint and to think up things that are worth while. The way to get out of misery is to plan to get out of it, and it looks to me as if most present efforts were addressed to inviting it to come in and overwhelm us. That would prove the contentions and fulfill the prophecies of nearly everybody. This thing is unwholesome and it doesn't help a little bit. Don't you think it would be timely to sound the slogan to call for more ideas and less poison gas? The blamed thing is getting on my nerves! I feel that people should turn over a new leaf and attend to business. Then we may find that things are not so threatening after all, provided always intelligent persons will use their heads rather than their wrath.

"The subject isn't exactly within our province, but I think the idea should be put over. What do you think about it?"

T'other editor spoke of the complimentary dinner given at the Waldorf to HENRY P. DAVISON on the preceding Saturday night. One had not been there, while T'other had, and the latter said that he too had had the material for an editorial in the back of his head, that during Mr. DAVISON'S speech it had assumed form, and, although the roads were different, it might be that the conclusions drawn were similar.

It appears that there were between 700 and 800 persons present at the dinner, and the preliminary laudatory addresses about the chairman of the War Council of the Red Cross were of a sort to make him very proud. But when the guest of the evening, who had won his way to fame and fortune by sheer ability, was called on to reply, after making acknowledgment of the words of praise, he stated that he would not apologize for the time he might take or for what he was about to reveal.

And there followed a picture of middle Europe, from the Baltic down through Poland, Czechoslovakia, Austria, Rumania, Serbia, Albania and Armenia that was drawn from facts. Famine stalks throughout the continent. Disease, especially typhus, is a plague. So is tuberculosis. There are no medicines. There is no sanitation. Over most of the territory there are hardly any doctors and such as there are lack all facilities. One doctor to from 50,000 to 100,000 persons with neither medicines nor transportation facilities couldn't do very much, and this is the situation over a great part of the area. The land is neglected and the people are flocking to the cities. Government changes in name every few weeks, but only in name. It does not exist in fact. Money has no value, so they cannot buy. In Vienna an ordinary automobile sold for sixteen times the former yearly salary of the Prime Minister. A mania for dancing has arisen in that great city where there is not one meal a day for the population, and wherever there is music the hungry people gather and dance until they fall exhausted. "That is not joy," said the speaker; "it is madness." When Russia changed her coat and fought for the Germans instead of against them she took 300,000 Allied soldiers and put them in a camp. There are 150,000 of these left alive and they will not last much longer.

These are just a few points of the speech that T'other editor recalled. Then he quoted some more.

"What do Europeans think of America now?" asked the speaker. "They say," he replied, "that we came over and helped magnificently; not because they called us, but for a great principle. When the Armistice was signed the President himself went over to make sure that principles of liberty should be included in the terms of peace. They say they believed that the great power and influence and ability of the American people were with them to secure a righteous peace, to read its terms into the treaty, and to help in the organization of reconstruction, which is one of the most difficult of human undertakings, especially among war-worn, crippled and distracted peoples. Then, they say, we have turned our backs on them. But now," he continued, "we have to do with the situation and not with what they say." And he declared it as his conviction after serious deliberation that the situation had got beyond the control of private initiative. It is so horrid, so ghastly, so immense, that only governments can stem the tide. England has been sorely stricken.

but she is coming through. She can take care of herself. France needs materials, and the country has been wretchedly mangled, but she has grand courage and she will take care of herself. The same may be said of Italy. The United States, on the other hand, is the only nation that has in abundance what that broad strip of hell needs. If the matter is taken in hand by our own Government, without the blight of politics at either end, and provision made for an army of mercy with doctors and food and sanitary engineers and the capacity to maintain order among people crazed by want and grief and misery, then England will follow to the limit of her ability, Japan will come along, and so will Holland and the Scandinavian countries and through a mighty effort the human conflagration may be extinguished. But if we do not do this thing; if we declare that it is none of our business and let them rot, the greater danger is not remote, but very near and very pressing, that all human effort will be unable to put down the triumph of madness over civilization.

"There," said T'other editor, "is the thing we need: the big vision, the big view. All of a sudden it seems as if the American people had dwindled, become little and mean and shabby in character. The big things we did before and during the war are all over with, and now we squabble. But even if this has become an epidemic degeneration of the mind, and men who once stood with clear vision, looking ahead, are now screaming in the halls of Congress like fighting cats and we have learned to despise them, it is no excuse for us if we imitate them. The world is in a parlous state and there's trouble in the air. The public intelligence is not high; not as high as it usually is. The popularity of some political candidates shows this. So the only safe attitude for thoughtful men is to take the long view, to look far ahead and to play the game fair. There never was a time when the responsibilities of every thinking man were so great and pressing as they are today."

And the editors agreed that at this point was the meeting of the roads. The more we mind our obligations the less we need fear for our rights. The Golden Rule still holds!

Senator Moses Answers a Question

MANY years ago there used to stand on Broadway near Wall street an old peddler who sold gum-drops; a grinning old remnant that appeared to enjoy his day at the market without doing anything, for we never saw him make a sale. He merely offered his wares—and smiled. Some wag had hung about his neck a sign which he maintained through the years as his contribution to the cheer of life until—and this, too, was long ago—he disappeared with other sweepings. The sign read "Terrible Excitement! Ferocious Slaughter of Prices! Giant Gum Drops Formerly 2c. Each Now 3 for 5c."

We are reminded of the episode by one of similar subtlety lately recorded in the transactions of the United States Senate. The Honorable GEORGE H. MOSES of Concord represents the sovereign State of New Hampshire and within that Commonwealth large quantities of dyes are used. Just as one star differeth from another star in glory, so one textile manufacturer differeth from another in opinion. We have no census of opinion of the New Hampshire mill authorities in regard to the pending legislation to maintain the coal-tar dye and allied industries as American institutions, but probably some favor the Senate bill and some hope for its defeat with a view to getting cheaper dyes from Germany pretty soon. We are also without specific information as to the relations of Senator MOSES with various textile manufacturers of his State, nor do we know what co-ordination of opinion as to public affairs may obtain between them. But Senator MOSES is against the dye bill; tooth and nail opposed to it. And Senator KENYON of Iowa, who back in 1914 claimed to be more "broad-minded" than the rest of us in considering the invasion of Belgium and German war methods, agrees with Senator MOSES about dyes.

Now, all persons familiar with chemical industry know that for the present this bill is necessary to maintain these establishments. Just because manufacturers usually have objected and probably will object to the lowering of duties on or the encouragement of importations of what they make, we need not be blind to present facts. The Senate bill is necessary to maintain the industry here no matter who makes money or loses it. And with it is coupled the development and maintenance of chemical preparedness for war. The American Chemical Society at its St. Louis meeting unanimously indorsed it, and neither dye producers nor any other type of manufacturer controls the American Chemical Society. To defeat the bill would be a great blow to national preparedness. Every chemist knows that.

But Senator MOSES opposes it. At the same time he is acting as advance agent for the candidacy of General WOOD for the Presidency. He went to Wilmington, Del., where he proclaimed the good General's many desirable qualities, while in Washington he had been engaged in opposition to the dye bill. Then CHARLES K. WESTON, of E. I. du Pont de Nemours & Co., wrote to Senator MOSES that he had listened with interest to his address and especially to his exposition of the General's favorable attitude toward national preparedness. Mr. WESTON also said he was outlining a publicity campaign in regard to the proposed dye legislation and he asked Senator MOSES to set him straight on the apparent contradiction of his attitude toward General WOOD'S candidacy on the one hand and toward the dye bill on the other. He signed himself frankly as of the publicity bureau of the du Pont company. It is a large manufacturer of high-class dyes and is intensely interested in the industry.

The question was perfectly fair and straight. We do not understand how Senator MOSES can be at once for preparedness and against the industrial development of organic chemistry to which the dye industry is the key. To anyone familiar with the situation this is a hard nut to crack. We should like very much to have it explained. We mean intelligently rather than oratorically explained. But on Friday last Senator KENYON of Iowa arose in all his dignity and cautioned his brother Senators against the sinister influences at work, not against the bill but for it. "I have in my hand," he exclaimed, "a letter addressed to a certain Senator who is opposing this bill and is also one of the managers of the candidacy of a certain gentleman for President of the United States . . . which is . . . a threat to the Senator in relation to that candidacy if he does not cease his opposition to the bill."

This brought the thinkers in from the cloak room and Senator KENYON proceeded to say that "This letter is used with the full knowledge and consent of the Sena-

tor, who *resents* it. And I am sure I ought to say that . . . General WOOD also resents the letter."

The crux of the whole matter is the resentment of Senator MOSES at a simple, honest question. We can hardly agree with Senator KENYON that he "ought to" say General WOOD resents it unless he really does; and even then it would be impolitic to advertise the fact. As a matter of fact, General WOOD was quoted Sunday as saying that he knew nothing of the letter until reading it in the newspapers. If the Senator could answer the question we suppose he would. Being unable to square himself with the facts as to preparedness, he "resents" it—and Senator KENYON makes the noise.

The Senate of the United States has not done itself proud during the last two years. The post-war degeneration in ideals and constructive thought from which the whole world has suffered has shown its incidence with peculiar sharpness upon that body. The resentment of the venerable Senator from New Hampshire is very like the great excitement of the late aged philosopher of the sidewalk. It is humorous, but not convincing.

Channels of Steel Consumption

IT IS always difficult to make even an approximate quantitative analysis of the consumption of steel in the United States. There always seems to be more steel consumed than can be accounted for, and when one comes to the item "all other," to be made up by difference, the proportion of that item is likely to be very large. The difficulty is experienced both when steel consumption is far below normal and when it is above normal. In "lean" years, like 1908 and 1914, there seemed to be scarcely any demand for steel, yet the production was at 50 or 60 per cent of capacity and there was a certain utilization of existing stocks besides.

As it is a matter of tonnage, outputs and capacities should be set down definitely. Disregarding rolled iron, which has run something like a million and a half tons a year for quite a while past, the production of finished rolled steel in 1906, when the industry operated fully at capacity throughout the year, was 17,401,911 gross tons.

As the finished product of one manufacturing process is the raw material of the next, the definition of "finished steel" must be by reference to process of manufacture. In the nomenclature employed in making up the statistics "finished rolled steel" is steel after it has experienced its last hot-rolling process, and of course also after the attendant shearing. Accordingly black plates for tinning as well as black sheets for use as black sheets or for galvanizing are considered rather than sheet bars, skelp is considered rather than welded pipe, the rods are weighed rather than the drawn wire or the rod billets, and thus with other commodities. In both 1912 and 1913 the output was a shade over 23,000,000 tons, and as 1912 saw light operation early in the year and 1913 light operation late in the year, the production and consumption in the twelvemonth July 1 to June 30 may be taken at 25,000,000 tons, likewise the capacity. In 1916, when capacity was increasing, and when late in the year transportation difficulties interfered with production, the output was 30,557,818 tons. There has not been even an approximate test of capacity since then, but the finished rolled steel output in ordinary times runs 76 per cent of the ingot output, and the ingot output in March, after continued increases for several months, was at the rate of 45,200,000 tons a year, from which it may be estimated quite accurately the rolled steel output was at the rate of 35,000,000 tons a year. Capacity under moderately favorable working conditions is about 40,000,000 tons a year, and let us hope that the estimate will soon be put to the test of actual experiment.

One is called upon, therefore, to analyze about 3,000,000 gross tons a month, or 35,000,000 gross tons a year. It is a very difficult task to find the channels of consumption that will absorb so much, but this does not suggest that the consumption does not occur or that it cannot occur for any length of time, since similar difficulties have been experienced ever since the steel industry has been in existence, yet the steel consumption of past years is an accomplished fact.

It used to be a custom to assume that "the railroads" consume 30 or 40 per cent of the steel output. It is doubtful whether that was ever true, and it certainly is not true now. The railroads will consume 2,000,000 tons or so of rails this year. Orders for steel cars have mounted to a few tens of thousands of cars. Steel wheels are included in the production statistics but cars being ordered do not all have steel wheels, so that at best twenty gross tons of steel per car would cover the case, meaning a consumption this year in car building of only between 1,000,000 and 2,000,000 tons. Locomotives will take but a fraction of this amount, and track repair material, steel for signaling and various miscellaneous uses but a fraction again of that. Car repair material, however, easily involves several hundred thousand tons, repairs lately required being so extensive as occasionally to require four or five tons of steel per car. In bridges, buildings, viaducts, etc., the railroads are doing very little. The requirements of the railroads of the country, all told, therefore, are not running much beyond 5,000,000 tons a year, and certainly they are far under 10,000,000 tons.

The individual skyscraper is an imposing example of steel consumption, but not many skyscrapers are erected in a year, and at this time such construction work is particularly rare. It is a very large skyscraper that required 10,000 tons of structural steel for the framework, and the incidentals of piping, elevators, etc., do not involve half again as much. The consumption of steel in such large buildings will do well if it runs into seven figures this year.

Estimates were that slightly more than 2,000,000 passenger automobiles would be built this year. The heavy cars are rare, the light cars numerous, and the average weight of all probably lies between 2,500 and 3,000 pounds, so that one gross ton of finished rolled steel per car would cover the case, this accounting for between 2,000,000 and 2,500,000 tons for the year, or not more than 10 per cent of the total production of the industry.

Thus far we have found about 10,000,000 tons out of the 35,000,000 tons to be accounted for. The remaining 25,000,000 tons is "all other," by difference, including agricultural implements and machinery of all descriptions, tools, hardware, pipe for oil development and transport, oil and other tanks, steel for small buildings, particularly "portable" garages, exports and a few other items.

Western Chemical & Metallurgical Field

California Fruit Growers Exchange Research Laboratory

The California Fruit Growers Exchange, a co-operative, non-profit, non-capital stock organization of 10,000 growers of citrus fruits, has established a research laboratory for the purpose of conducting investigations along fundamental lines on chemical problems relating to the citrus fruit industry. The first work of the laboratory will be in connection with the utilization of the lower grades of fruit.

Lemon growers of the California Fruit Growers Exchange in 1914 established the Exchange Byproducts Co. at Corona, Riverside County, which has since then been engaged in the production of U.S.P. citric acid and lemon oil from cull lemons. Later, the orange growers organized the Exchange Orange Products Co. for the purpose of utilizing the lower grades of oranges in the manufacture of marmalade and other products.

The research laboratory of the exchange is for the purpose of working out the problems incident to the production of new products from all varieties of citrus fruits and of co-operating with the byproducts factories in their chemical problems, while each byproducts factory has also its own plant control laboratory and chemists. Other lines of work will be taken up later.

The laboratory is located in the building of the Exchange Byproducts Co. at Corona. C. P. Wilson, for many years with the Bureau of Chemistry of the U. S. Department of Agriculture and for the last three years chief chemist of the Exchange Byproducts Co., will have charge.

Prospective Power Development in California

There are at present ninety-one power plants in the State of California which are operated by the large power companies. The transmission lines of these companies are to a large extent interconnected and more complete interconnection and the enlargement of existing connections are now under construction. Of these plants sixty-seven are hydro and twenty-four are steam; The installed generator capacity is 513,000 kw. for the hydro plants and 279,000 kw. for the steam plants, a total of 792,000 kw., or 1,063,000 hp. This is the largest system of interconnected companies in the world, the combined output for the year 1919 being more than three billion kilowatt-hours.

There are at present under construction thirteen power plants with a total installed generator capacity of 270,500 kw.; of this, 85,000 kw. will be steam generated. These additions, listed below, will be completed within a year and indicate a total installed primary in condition for operation in April, 1921, of more than 1,400,000 hp.

The outstanding feature of these developments is not the magnitude of the installed power, but the fact that the various plants are interconnected and the length of the interconnected transmission lines, which extend from Oregon to Mexico. One essential requirement for power to be supplied to industries is reliability; the interconnection, together with the favorable climatic conditions, practically assures this. Taken together with weather which permits of maximum production throughout the year, this will result in California becoming an increasingly important industrial section of the country. Statistics recently published by the *Electrical World* indicate that approximately 10 per cent of the potential power is now developed in Califorina, which practically assures the future supply.

The Smelters Steel Co.

The Smelters Steel Co., of Seattle, Wash., is now producing soft gray iron castings of unusual toughness and purity from magnetite iron ore in an electric furnace in one operation. G. Lewis Casey has been working on the problem for many years and has developed the process to such an extent that economic success appears to be assured. There is a good market on the Coast for soft gray iron; unfilled orders at $65 per ton indicate that the quality of the product is satisfactory to the consumers.

The company's plant, which consists of a modern foundry building and fireproof transformer room, is located on a 5-acre tract, with about 1,000 ft. of water frontage, at Seattle. Four 440-kva. transformers are already installed. One furnace is in operation, a second under construction, and as soon as this is finished two additional furnaces are to be built; the estimated output will be 15 tons per day.

Magnetite iron ore, containing over 52 per cent iron with but small amounts of deleterious impurities, is obtained from an extensive deposit on Dean Channel, B. C. The deposit is at tidewater and the ore can be easily bunkered for shipment by boat to Seattle. In addition to the ore deposit the company owns a valuable water power near the mine and a tract of timber land. The manufacture of charcoal will be undertaken.

The British Columbia Government is particularly anxious to develop an iron and steel industry within the province and negotiations are now under way with the Smelters Steel Co. looking toward the establishment of a smelting plant at the mine. With the iron bounties act, assuring $3 per ton on all pig iron produced, and with further possible assistance from the iron ore supply act, the erection of a plant costing approximately $500,000 at the mine at no far distant date seems a possibility.

The Metallurgical Research Department of the Utah State School of Mines

Equipment of a Wide Variety of Types Is Available for Testing Ores in the Intermountain Region—Besides General Work in Ore Dressing, This Station Is Doing Much Work on Chloride Volatilization and Oil Shales

By L. W. CHAPMAN

THE Metallurgical Research Department of the State School of Mines was established by the Utah Legislature in 1913 for "finding ways and methods of profitably treating low-grade ores, of securing a higher percentage of extraction of metals from their ores, for obtaining other information that shall have for its object the benefit of the mining industry and utilization and conservation of the mineral resources of the state and for the publication and distribution of bulletins."

By an agreement with the United States Bureau of Mines the work of this department is under the direction of metallurgists of the Bureau assigned to duty with headquarters at the University of Utah.

At present the technical staff of the U. S. Bureau of Mines connected with this department is as follows:

Thomas Varley, metallurgist in charge.
C. A. Wright, hydrometallurgist.
J. C. Morgan, assistant chemist.
E. P. Barrett, assistant chemist.
R. E. Head, metallurgical assistant.
H. D. Gavin, refinery engineer.
L. C. Karrich, junior refinery engineer.

The present staff of the Department of Metallurgical Research, State School of Mines, University of Utah, consists of:

Joseph F. Merrill, director.
R. H. Bradford, professor of metallurgy.
Robert S. Lewis, professor of mining.
J. R. Phoenix, analyst.
H. W. Clark, laboratory assistant.

From 1913 until the Legislature met in 1919, $7,500 had been appropriated yearly by the state to carry on this research work. The last Legislature, however, increased the amount $5,000 a year and appropriated $25,000 for the ensuing two years. During 1918 certain mining companies and business men of Salt Lake City and other parts of the state subscribed $21,000, which, together with an additional $15,000 appropriated by the state, was used for the enlargement of the buildings, increasing library facilities and remodeling and buying new equipment for the ore-dressing and metallurgical laboratories.

A large fireproof building (shown in Fig. 1) 75 ft. long, 40 ft. wide and two stories high has been erected and the offices of the U. S. Bureau of Mines and the Department of Metallurgical Research, as well as laboratories and lecture rooms, have been installed.

Up-to-date machinery for ore dressing and flotation and other equipment necessary for properly carrying on research and experimental work have been installed, making one of the most complete and up-to-date laboratories of its kind in the United States.

Provision has been made for six fellowships during the fiscal year 1919-1920. Each of these fellowships pays an annual income of $720 and covers a period of twelve months. The holders of these fellowships are required to register for courses of instruction in the University of Utah and become candidates for the master's degree, and, while these "fellows" are under the general direction of the metallurgist in charge, the detailed supervision is under other Bureau of Mines metallurgists and chemists and the professors of mining and metallurgy of the University of Utah.

Ore-Dressing Laboratories

For testing ores by gravity concentration and flotation it is necessary that the laboratories should be designed to handle ores in amounts varying from a sample of only a few pounds to lots of several tons in weight. The sampling room for the metallurgical laboratories is equipped with all machinery necessary for fine grinding and the reduction of comparatively large samples to small and easily handled bulk. The equipment consists of an Allis-Chalmers gyratory sample grinder, a Universal jaw crusher having an opening 3½ x 6 in., Allis-Chalmers laboratory rolls 4 x 9 in. in size, a McColl disk pulverizer having 9½-in. disk, and an Iler disk pulverizer having 6-in. disk. Five sets of Jones sample splitters of different sizes are used for cutting out the final sample.

Some special grinding has been done on graphite ores. For this purpose a 12-in. Burr mill of Sprout-Waldron manufacture has been installed.

The designs of modern concentrating plants are usually based upon the results of small-scale tests on the ores to be treated. These tests are generally divided into two classes. The first or preliminary testing is

FIG. 1. METALLURGICAL BUILDING, UNIVERSITY OF UTAH

done on lots of a few pounds only. The larger or controlling tests are carried out on machines which will handle from 150 lb. to as much as a ton of material in an hour. Experience indicates that the results obtained from the first or preliminary tests, if they are carefully done, give a very reliable indication of the work to be expected in the larger testing plant and also in the commercial mill.

For the work of coarse concentration two Hartz jigs are available. The larger jig has two compartments, each 7 x 15 in. in size. The smaller jig has two compartments, each 4 x 6 in. These jigs have an automatic concentrate discharge and the usual adjustable eccentric drive. For the work of fine concentration several tables are available, a Wilfley table 12 x 24 in., a 15 x 30-in. Deister Plat-O table and an Overstrom Universal table 18 x 44 in. The effect that different styles of riffling may have is noted by using interchangeable table decks.

There is also a half-size Deister-Overstrom finishing table which is set up independently of the other machines and is provided with a mechanical feeder with a capacity of approximately 75 to 100 lb. of ore, which can be fed at a uniform rate over this table. There are also two half-size Wilfley tables which can be riffled according to the nature of the ores and sizes treated.

FIG. 2. PART OF FLOTATION LABORATORY

The laboratories are equipped with a small ball mill with a capacity of 3 kg. (7 lb.) of ore, which makes it possible to crush any wet material to be treated by flotation.

An Abbe jar mill equipped with Silex pebbles is also provided, with a capacity of approximately 3 kg. of ore. By having the two kinds of fine grinding mills, it is possible to get comparative data on the effect of crushing with iron balls against iron with that of pebbles against Silex lining.

Flotation Laboratory

The flotation laboratory (Fig. 2) is equipped with a variety of testing machines, of the mechanical, pneumatic, and combination types. These consist of a small Callow testing machine operated entirely by air agitation; a Jones-Belmont machine, having a capacity of about 2 kg. (4.5 lb.) of ore, which is a combined air and mechanical agitation machine; a small K. & K. machine which is an aërating and a mechanical type machine, and a Federal-Varley machine which is the straight mechanical agitation type somewhat similar to the M. S. machine, having a capacity of from 3 to 5 kg. (7 to 12 lb.) of ore. There are also two small Janney laboratory size machines which are used for small-scale straight mechanical agitation tests, and a Ruth flotation machine which is of the mechanical agitation type, the impeller being arranged in such a manner as to create a suction of air through the hollow impeller.*

These machines differ in size and capacity so that samples ranging from ½ to 5 kg. (1 to 12 lb.) can be treated at a time.

Suction filters are used for dewatering the products, and gas and steam heaters are provided for drying all the products made. A small Root blower is provided in the laboratories which gives the proper amount of air for the pneumatic machines. This can be controlled in order to give any volume or pressure desired.

A large supply and variety of various flotation oils and other reagents used in flotation are kept on hand. These are renewed from time to time, as it has been found that the oils change their characteristics somewhat in long standing.

Arrangement of Equipment for Tonnage Tests

The object of having the equipment arranged for large-scale tests so that quantities of a ton or more of ore can be handled at one time, applying the same treatment as that given in commercial concentrating plants, is twofold:

First, so that the results of the small-scale tests may be substantiated by larger scale experiments.

Second, so that students of the School of Mines and Engineering may have a chance to carry out tests under direction and thus gain experience of operating the various machines and also of making the metallurgical calculations that are required in a report on a complete concentration test.

The keynote of the large-scale testing laboratory is flexibility; an ore can be crushed to comparatively coarse size and can then be treated on jigs or, after fine grinding in one of the various mills, it can be treated on concentrating tables, on slime tables, or by flotation. If a complex lead-zinc-iron ore is to be tested, provision is made either for regrinding the middling or for drying and roasting the same, followed by magnetic separation of the zinc and iron.

The crusher used is of the Dodge type, size of opening 7 in. x 9 in., speed 260 r.p.m. The usual size of the crushed product is from ½ to ¾ in., a size most suitable for the set of Allis-Chalmers 12 x 16-in. rolls operating at a speed of 155 r.p.m. These rolls can be set to crush to any desired size, but usually produce material ¼ in. or under. From the rolls the ore passes to an elevator having a lift of 32 ft., delivering the product to screens.

The first screen is a double-cone trommel 30 in. long. The inner screen has ⅜-in. holes and the outer screen ¼-in. holes, and is used to give a product suitable for further sizing with a Mitchell vibrating screen. This screen has a large capacity, is very efficient, and can be readily changed so that any desired size can be obtained as an undersize product.

Ball Mills and Fine Crushing Equipment

When fine crushing for table and flotation concentration is desired, the undersize material from the first screen passes directly to two storage bins, each holding approximately one ton. From these two bins the

*For a general description of most of these machines see an article by Fahrenwald in Chem. & Met. Eng., vol. 19, pp. 77 and 129.

ore can be distributed to any one of four grinding machines together with necessary amount of water.

(1) A No. 32 Marcy mill in which steel balls are used as the crushing medium. The mill has a maximum capacity of about one ton per hour at 35 r.p.m. when crushing to 8 mesh. The overflow or slime goes to a pump.

(2) A 3-ft. x 8-in. Hardinge conical mill, using either flint pebbles or steel balls as the grinding medium and operating at 28 r.p.m. The discharge from this mill or the Marcy mill may be sent to a Dorr classifier, the oversize being returned to the mill for regrinding.

(3) A 3½-ft. Huntington mill operating at the rate of 80 r.p.m. Screens are used to control the size of the product from the mill.

(4) A stamp mill provided with three 250-lb. stamps. The drop is 6 in. and rate 90 r.p.m. These stamps are used for crushing ores that contain free gold or silver. An amalgamation plate, 24 in. wide x 48 in. long, is also provided directly in front of the stamps.

All crushed material and the overflow from the Dorr classifier are pumped to the second floor of the mill building, where they are discharged into a mechanical classifier of the Dorr, Akins, or Esperanza type. The sands can be sent either to a three-spigot hydraulic classifier, which supplies a classified feed to the concentrating tables, or to a single Deister cone baffle classifier, which gives a table feed of any desired size.

Tables

The table equipment, shown in part in Fig. 3, includes two Wilfley tables with decks 3 ft., 4 in. x 7 ft., 6 in. long, one Deister-Overstrom finishing table, with deck 3 ft. wide x 7 ft. long, and one Overstrom roughing table of approximately the same area. The riffling on these tables can be changed and the speed of the table and length of stroke regulated.

Flotation Equipment

The flotation equipment consists of a Janney flotation machine patterned after the standard Janney machine and is of the combined mechanical and air type. This machine treats several tons of ore per day and does excellent work on small lots. The rate of feed is under perfect control and the amount of oils used is carefully regulated. By special arrangement the first or rougher concentrates can be stored and re-treated or cleaned in the same machine.

A flotation machine was furnished by the Arzinger Machinery Co., Nashville, Tenn., which has been successfully used in floating the graphite in the ores of the Alabama graphite fields and on the zinc ores in Tennessee.

A straight mechanical, two-compartment M. S. flotation machine with a variable speed motor completes the equipment.

When treating complex lead-zinc-iron ores it is often necessary to give middling products from the tables a slight roast in a furnace in order to make the iron magnetic. The furnace product is then treated in a three-magnet laboratory-size Campbell magnetic separator. Each pole is connected with a meter and rheostat regulating the fields so that the poles can be given different magnetic intensities. In the case of many chromium and manganese ores this magnetic separator can be used to separate magnetite, garnet and other ingredients from the chromite and manganese.

Considerable work has recently been done on the massive low-grade alunite deposits from Piute County, Utah. Experiments have been made with the idea of economically obtaining potash from the ores by a simple roasting-lixiviation process. The objects of the tests are as follows:

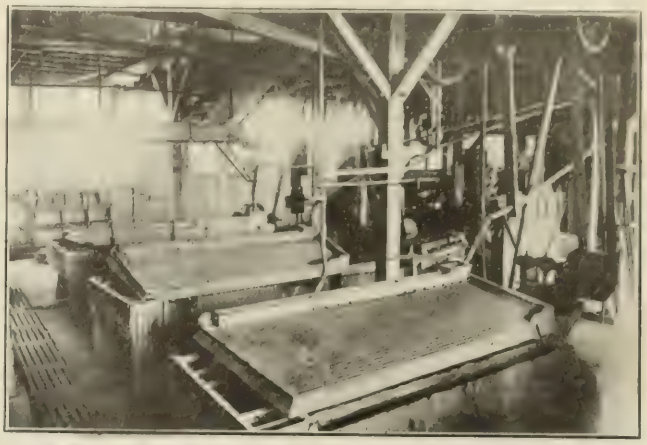

FIG. 3. PART OF ORE-DRESSING LABORATORIES

1. The roasting temperature best adapted to a high recovery of potash by subsequent lixiviation.

2. The size of crushed ore which on roasting at the most desirable temperature gives the best extraction-crushing economy.

3. Whether there is a loss of potash by volatilization during roasting operations.

Further tests on a large scale are now under way. These tests are to be carried on with the object in view of recovering the alumina as well as the potash.

Chloride Volatilization Process

The chloride volatilization process has recently been applied with considerable promise of success to the recovery of metal in oxidized ores and is one of the major problems being studied. The process, briefly stated, consists of the following steps:

First, crushing to a degree of fineness depending upon the character of the ore.

Second, mixing with chloridizing agents either alone or with other reagents. Sodium and calcium chlorides have been found to be effective chloridizers. Sulphur, either in the form of natural sulphur or as pyrite, has been found to aid in chloridizing, as has also lime, although the general effect of these reagents is yet to be worked out.

Third, furnacing to effect chloridization and the volatilization of the metal chlorides formed.

Fourth, recovery of the volatilized metal chlorides.

Fifth, treatment of volatilized chlorides to obtain the values in salable form, preferably with regeneration of the reagent.

Chloridization of the precious metals prior to subsequent lixiviation is an old practice. Volatilization of metals as they form into chlorides was a recognized source of loss and in practice was naturally to be avoided. Not until 1901 is there any record of an attempt to put this loss by volatilization to any gain. At this time, Messrs. Poole and Croasdale, using salt and sulphur, endeavored to volatilize a high percentage of all the valuable metals contained in the ore. Although not financially successful, due primarily to failure to collect the volatilized chlorides economically, their endeavor established the possibilities of this process.

The successful application of the Cottrell electric precipitator in the removal of solids from smelter gases was an important factor in the revival of the volatilization process and finally the feasibility of chloridizing and volatilizing the metals from ores by the use of a salt roast without the use of sulphur was established, at least for certain ores.

Crushing

The fineness to which ore must be crushed is dependent upon the character of the ore. Preferred practice with those ores which respond best to volatilization is to crush not finer than through 30-mesh. Such crushing involves the use of both crusher and rolls. Reagents must also be crushed to a fineness corresponding to that of the ore to give the best results.

Reagents

Two reagents have been successfully applied as chloridizing agents—sodium and calcium chloride. Extractions obtained with these two chloridizers vary with different ores and different metals, and while neither is uniformly better, common salt, being cheaper in western localities, will undoubtedly be used as the primary chloridizing agent. Present indications are that a slag consisting chiefly of calcium chloride will result from the reduction of the fume in most cases and will be re-used as a chloridizing reagent.

Besides the chloridizing agents, sulphur, pyrite and lime have been found to be beneficial with certain ores.

Reagents and ore are thoroughly mixed to insure intimate contact.

Furnace

Ore, after being mixed with the desired reagent, is fed into a horizontal cylindrical kiln similar to those used in cement mills, where the mixture is heated to effect chloridization and volatilization. On amounts of material of 100 lb. or over there is available a kiln 20 ft. long with an inside diameter of 13 in. for the last 15 ft. and 21 in. inside diameter for the first 5 ft. from the fire end, and also a 6-hearth Wedge roaster arranged for either muffle or direct firing. A reverberatory furnace is soon to be installed.

The cylindrical kiln is fired by an oil burner, the flame being directed into the open end of the kiln, as shown in Fig. 4. Ore is fed in by a worm feed so that it discharges into the kiln at a point about 3 ft. from the cold end, giving it a travel through the kiln of about 17 ft. The rate of revolution can be varied so that ore may be held in the kiln for periods of from one hour to two hours, one-half of this time being in the enlarged section where the maximum temperature is obtained.

Flue System and Cottrell Electrical Precipitation

The cold end of the kiln extends into a sheet iron cooling and settling chamber, where a large amount of the heavier solid particles drop out of the gases. From the settling chamber the gases pass through a short flue to a second settling and distribution chamber, where the greater part of the remaining dust particles are deposited without any great amount of the metal chloride fume. From the settling and distribution chamber the gases pass up through a flue and discharge by passing down through a small Cottrell precipitator. After passing through the precipitator the gases are to a large extent free from metallic chlorides and pass through an exhauster to the stack. No further attempt is made to clean the gases after they leave the Cottrell. At the present time this phase of the problem is receiving considerable attention.

The Cottrell precipitator at the Salt Lake City station is constructed in two units, each with a capacity of 1,500 cu.ft. of gas per minute. The units are 17½ ft. high x 4½ ft. square over all. Each unit receives the gases through a 15-in. pipe to the top chamber of the treater. The gases pass from the top chamber to the bottom chamber through twenty precipitating tubes; these are 6 in. in diameter and 8 ft. long. Gases are exhausted from the bottom chamber into the stack by an 18-in. fan. The units are exactly alike, and so arranged with slide dampers that either one or both of the treaters can be used at any time. The discharge electrodes are made of chromel wire.

The treater transformer is rated at 5 kva., 220-440/100,000 volts. The rectifier has a disk 36 in. in diameter and is driven by a 3-hp. synchronous motor at 1,800 r.p.m. The control of the voltage of the transformer is obtained by means of an auto-transformer which is arranged to supply power at any voltage between 55 and 440 by steps of 55 volts. A theater dimmer is used for the control between the auto-transformer voltages. By this arrangement any voltage from about 5,000 to 100,000 can be obtained from the secondary of the high-tension transformer.

Treatment of Fume

The fume, consisting of metal and sodium chlorides as collected in the treaters, must next be treated for the recovery of the contained metals. At present this part of the work is the least advanced of any, but is being taken up as one of the most important problems of the process. It is probable that the fume from each ore will in itself offer a distinct problem, although these

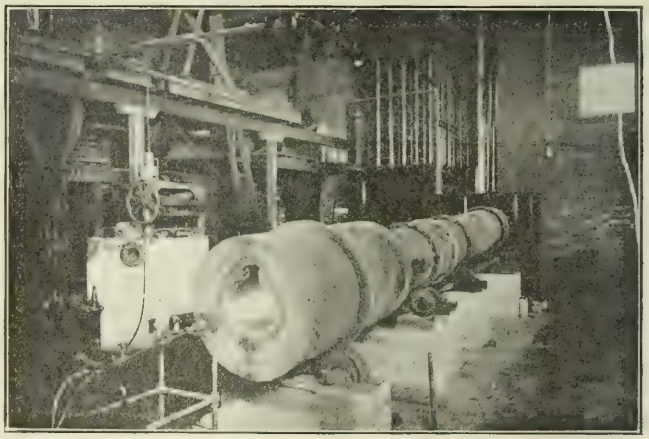

FIG. 4. VOLATILIZATION KILN

fumes will fall in a few general classes. Four general classes have already been met with as follows:

First, lead-silver-gold fumes; second, copper-silver-gold fumes; third, lead-copper-silver-gold fumes; fourth, very complex fumes, as for instance lead-zinc-copper-mercury-silver-gold fumes.

While no general statements as regards the treatment of the fume can be made, several solutions are suggested. First, it may be leached, with subsequent precipitation of the metal from the leach liquors; this method of treatment will probably be resorted to, partially at least, in treating the complex fumes; second,

metal may be directly reduced from the fume; this is accomplished by mixing the metal chlorides with lime and a reducing agent such as coke, and heating to a temperature above the melting point of the metal being reduced. The products formed in this case are bullion and a slag composed chiefly of calcium chloride. It seems probable that this method can be applied to such fumes as lead-silver-gold or copper-silver-gold combinations.

Ores Amenable to Volatilization

The volatilization process at the present time seems to have its greatest application to low-grade oxidized ores. The best results have been obtained with simple low-grade lead ores, copper ores, lead-silver ores and

FIG. 5. CHEMICAL LABORATORY

copper-silver ores. Considerable success has been met with also in the more complex oxidized ores carrying copper, lead, silver and zinc, although the last named is not volatilized with any very great degree of success. Little general success has been met with so far on the treatment of complex sulphide ores, although evidence indicates that it may be possible to treat this type of ore after the behavior of the simpler oxidized ores during volatilization is more generally known.

Oil Shale

Investigational work on oil shales has been carried on at the Salt Lake City station for over a year. The work thus far has been along two lines, (*a*) study of methods of assaying oil shales for commercially recoverable oil and ammonium sulphate, and (*b*) investigations of a retorting plant together with a study of the products produced by it from different shales of the Rocky Mountain country. Both these investigations are practically completed, and have given valuable information as to the nature of the products to be obtained from oil shales and as to the best methods of treating the shales themselves.

Messrs. Gavin and Karrich intend to produce sufficient oil from shales to make a study of the refining of the oils on a scale large enough to determine the commercial value of the refined products.

The Bureau of Mines at the Salt Lake station has accumulated a large amount of data pertaining to all phases of the oil-shale industry, both in order that the investigators for the Bureau could have easy access to the best literature and data on the subject and that the Bureau might be well equipped to answer inquiries and requests for information on the subject of oil shale.

In order to handle rapidly the large volume of analytical and chemical work necessary in making metallurgical tests, the Salt Lake City station is equipped with three laboratories: the main chemical laboratory, shown in Fig. 5, the fire assay laboratory and the fellowship laboratory. Together they form a laboratory system equipped with all modern appliances necessary for rapid and accurate work.

The microscopic examination and study of the physical characteristics of the complex ores has been one of the problems which has received considerable attention. Methods of preparation and study developed during the course of the investigation have resulted in the discovery of many mineral relations in complex sulphide ores, the knowledge of which has been of much value in determining the treatment to which the ore would be more amenable.

The U. S. Bureau of Mines in its co-operative work with the University of Utah maintains an excellently equipped microscopic laboratory in the metallurgical building, and this phase of investigation is applied to the problems in ore-dressing which constitute the work of the station.

The material for this description was kindly furnished by Thomas Varley, metallurgist in charge of the Bureau of Mines Station, supplemented by their Bulletin No. 11.

Foreign Trade of Australia for 1918-19 Shows Increase in Exports

Detailed figures of Australian imports and exports for the fiscal year ended June 30, 1919, as published at the end of the calendar year, show the value of imports to be £93,485,050, and the exports £106,805,985, an excess for exports of £13,320,935. A summary of the foreign trade for the four months of the new fiscal year, July-October, shows that the excess of exports was increasing, for with imports totalling £24,750,555, a reduction of £6,998,650 from the figures for the corresponding period of 1918, the exports for these four months increased about 40 per cent, or from £25,724,252 in 1918, to £46,726,503 in 1919. Almost half of the year's exports came under classification VI, "animal products, mainly unmanufactured, not foodstuffs." The amount for the fiscal year was £47,665,869, of which £42,766,775 represented wool, and £4,403,518 hides and skins. Meats were exported to the amount of £8,862,246.

Exportations of wheat totaled £11,334,665, and flour £5,818,785. In the four months July-October, 1919, exports of Class VI, defined above, were £18,476,285, animal foodstuffs £6,954,665, and vegetable foodstuffs £13,661,407. New South Wales was the largest exporter in these four months, with a total of £17,354,323, and Victoria ranked second with £15,192,284.

The largest items of import for the fiscal year were textiles, amounting to £25,956,450; wearing apparel, £3,812,453, of which hosiery comprised £2,098,897; tinned plates, £1,134,337; paper, £5,390,960; timber, £1,359,251; drugs and chemicals, £4,016,447; rubber manufactures, £1,164,317. In the four months of the new fiscal year importations of textiles and wearing apparel were less than half of those of the same months of 1918, while importations of machinery nearly doubled, an indication of the rapid growth of the movement to make Australia self-sufficient in the matter of clothing.

Photographing Etched Sections at Low Magnifications

By J. H. G. Monypenny
Chief Metallurgist, Brown, Bayleys Steel Works, Ltd.

THE advantage of being able to photograph sections of steel at low magnifications, using the same type of illumination as is used for higher magnifications, i.e., vertical illumination, has been apparent to those employed in metallurgical laboratories for a considerable time. Methods somewhat similar to those described in the short article by F. B. Foley in CHEMICAL & METALLURGICAL ENGINEERING, vol. 21, p. 140 (Aug. 1, 1919), have been in use in the writer's laboratory for a number of years. As these methods differ in certain details from that described in the article mentioned above, a description of them might be of interest.

For very low magnifications (up to about four diameters) the method employed is practically the same as that described by Foley. The lens used is a 5½-in. anastigmat and with the length of camera available in our laboratory, reproduction from natural size up to

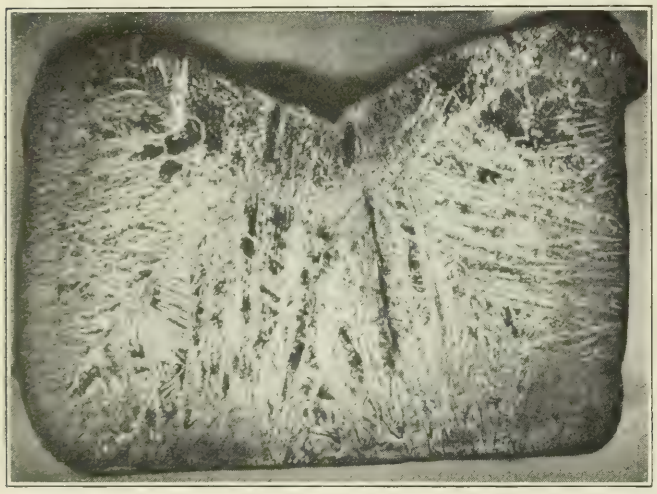

FIG. 1. LONG DENDRITES FROM CHILLED TEST-INGOT. ETCHED WITH COPPER REAGENT. × 3¼

four diameters may be obtained. Such magnifications are especially valuable with sections etched with one of the "copper" reagents (such as Stead's, Rosenhain's or Le Chatelier's). These require a low magnification to simulate macroscopic examination as a general rule. Fig. 1 (3¼ diameters) is an example of this. It represents a section from a small sample ingot taken for analytical purposes from an electric furnace, and shows the development of long "chill-crystals." Fig. 2 (from a file blank burned in forging) was also taken by this method and shows (2¾ diameters) the decarburization formed both on the skin and around the cracks.

When illuminating these large sections one should

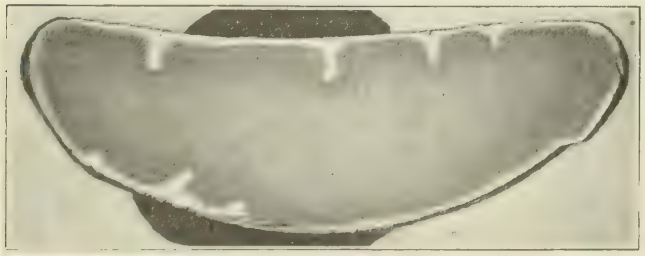

FIG. 2. FILE BLANK BURNED IN FORGING. ETCHED WITH COPPER REAGENT. × 2¾

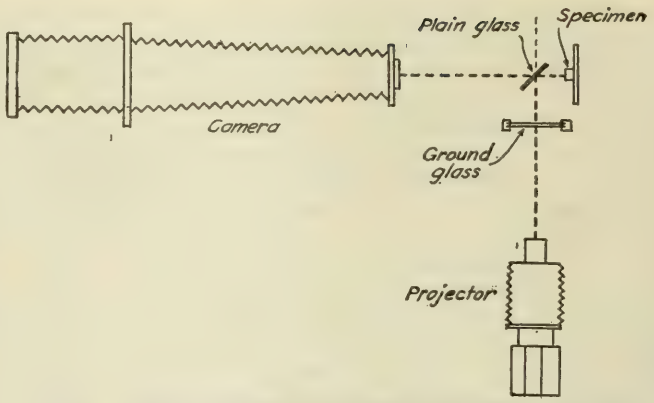

FIG. 3. ARRANGEMENT FOR PHOTOGRAPHY AT LOW MAGNIFICATIONS GIVEN IN FOLEY'S ARTICLE

endeavor to produce an evenly illuminated area, considerably larger than the section, on the ground glass (shown in the diagram, Fig. 3, from Foley's article) and the latter should be placed quite close up to the section.

For higher magnifications a 35-mm. projection lens (made by Zeiss) is employed by us, giving a magnification from nine to twenty-five diameters (with the minimum extension available on the camera a magnification of nine diameters is obtained—less could be obtained with a camera closing to a greater extent), and for these a somewhat different method of illumination is used.

If one is using an enlarging lantern or a projection lantern, then, in order to get satisfactory lighting, the condenser must be close to the negative or slide and must focus the illuminant on the projection lens, as is well known. The same principle is used for photographing sections and the arrangement of condensers is shown diagrammatically in Fig. 4. This sketch shows the 35-mm. lens *A* attached to the microscope tube and the section *B* on the stage. The microscope used is the large "works" model made by Watsons, London, which has a very wide tube—the inner draw tubes are removed for use with this lens. Condenser *D* forms a considerably enlarged image of the illuminant *C*, which now is a 500-cp. Pointolite lamp, a tungsten arc lamp made by the Edison Swan Co. and in the writer's

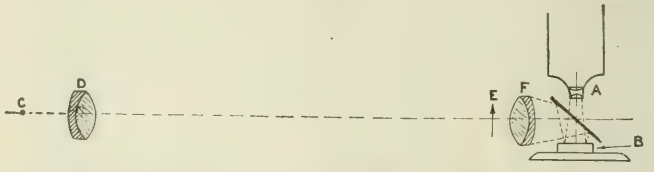

FIG. 4. MONYPENNY'S ARRANGEMENT FOR MAGNIFICATIONS OF 9 TO 25 DIAMETERS, USING 35-MM. ZEISS PROJECTION LENS

experience the best illuminant yet devised for photomicrography.[1] Such enlarged image is focused at *E*, close up to the second condenser *F*, and the latter in turn focuses the image, after reflection at the 45-deg. cover-glass reflector and the surface of the specimen, on the lens *A*, as indicated roughly by the dotted lines. The condensers used are 2⅛ in. diameter and 2⅝ in. focus, and it is possible to illuminate evenly a section about 1 in. diameter; this is more than required, as the field of the lens is only about ⅝ in. diameter. Figs. 5, 6 and 7 show some of the results obtained; I may add that most of these photographs were taken eight or ten years ago.

[1]See CHEM. & MET. ENG., vol. 22, p. 281 (Feb. 11, 1920).

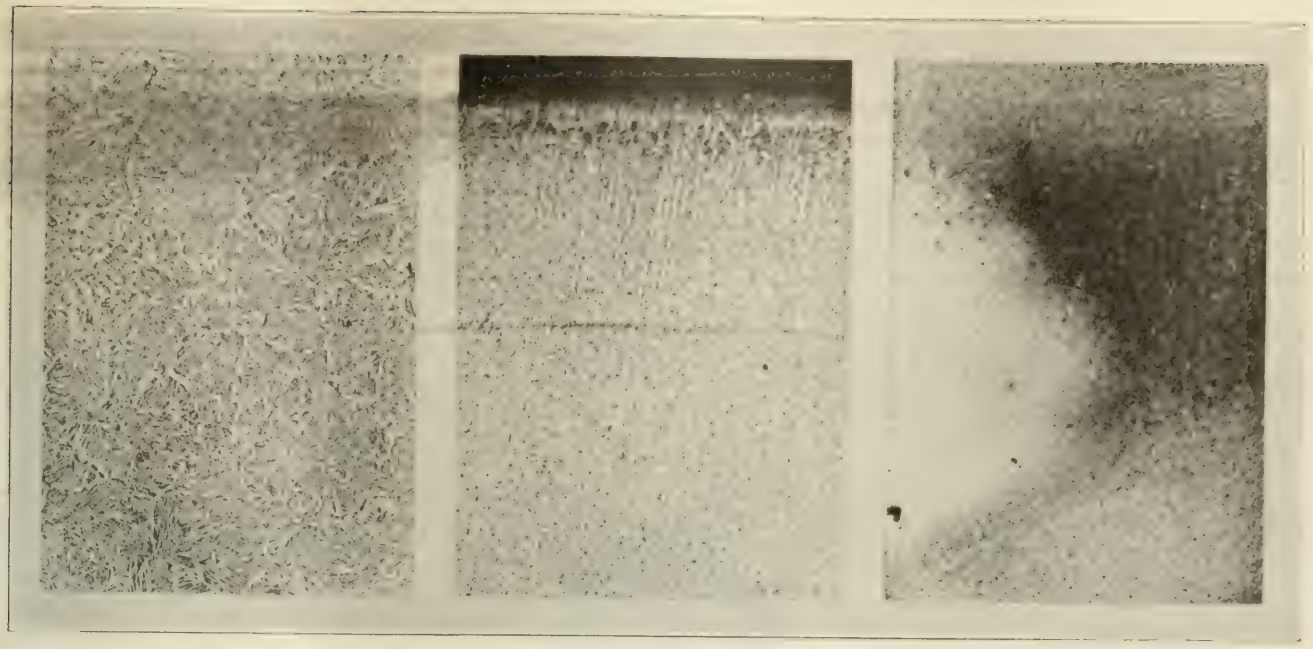

FIG. 5. OVERHEATED STEEL. × 10

FIG. 6. MILD STEEL BLOOM CUT BY OXY-ACETYLENE TORCH. × 10

FIG. 7. CARBON SEGREGATIONS AROUND AN UNSOUND SPOT. × 8

It is obvious that these low powers are of special value where either the structure is very coarse or where one wishes to show the variation of structure over a fairly large area. For example, Fig. 5, at ten diameters (originally exposed at twenty diameters), shows far better than a photograph at say 100 diameters the structure of the sample of overheated steel from which it was taken. Fig. 6 (at ten diameters reduced one-half from the original exposure) represents a section taken from a mild steel bloom cut by the oxy-acetylene blowpipe, and enables one to show in a single photograph the gradual change of structure produced. Fig. 7 (at eight diameters reduced one-half from original) illustrates another type of photograph for which the ordinary microscope objective would be quite useless; this shows the size of, and distribution of carbon in, an unsound segregated area. This actual example is rather unique, showing, as it does, high- and low-carbon areas in close proximity.

With regard to the proper exposure: Using a slow-process plate with the 35-mm. lens at twenty diameters, on a section similar to those shown in Figs. 5 to 7, two to four seconds would be required.

As mentioned above, the tube of the writer's microscope is very wide and comparatively short (2 in. diameter and 4⅜ in. long) and this enables one to use practically the full field of the 35-mm. lens; with a narrower tube, of course, part of the field would be cut off. In such cases one may do without the microscope and mount the lens on a small fitting (with either spiral or rackwork focusing) on the camera front. In one or two cases the writer has done this and has succeeded in obtaining a 6½-in. circle at nine diameters (i.e., a field of 0.72 in.). The definition in this case was not quite perfect around the edge, but it was sufficiently good for the purpose.

It may not be out of place to mention that when taking a photomicrograph without using an eyepiece it is necessary to avoid reflection from any metallic surface inside the microscope tube. The latter should be coated with a dead black varnish, but it is generally advisable to put in a lining of black cloth. Such a lining can easily be made by gumming a piece of black cloth of the required size on to a similar piece of fairly stiff paper, then rolling into a cylinder (cloth inside) which can be slid into the microscope tube.

For the 45-deg. reflector the writer uses a piece of thin microscope-cover glass 1⅝ x 1¼ in., mounted in a light metal frame which fits on the 35-mm. lens. The frame carrying the glass is pivoted, allowing the illumination to be adjusted to a nicety. The glasses may be obtained in various sizes up to 4¼ x 3¼ in., but as they are very brittle, it is advisable to use a thin lantern-slide glass for the lowest powers (i.e., from one to four diameters), which require a larger reflector.

Sheffield, England.

Wages in Japan

Commercial Attaché James F. Abbott, Tokyo, Japan, says that there is practically no regular employee now in Japan who does not get a bonus of from one to three and even five months' salary at New Year, this being a regular institution in Japan and applying to all government employees as well as to employees of private concerns. In many cases this bonus is paid twice a year, and important officials frequently receive a sum many times more than their annual salary. Another method of assisting their employees, adopted by some large factories, is to issue a rice stipend in addition to the regular salary. Some companies give board at the rate of 9 or 10 sen a day which actually costs the employer 25 to 35 sen. The employers prefer this method, as it is easier to reduce the labor outlay, should the cost of rice fall, than if the wages were increased.

Blending Casinghead Gasoline and Naphtha

A new edition has been prepared of the chart for blending casinghead gasoline and naphtha, computed by Clarence Netzen for the Bureau of Mines, Department of the Interior. This chart provides an easy method of determining the amount of naphtha to be used per gallon of casinghead gasoline to obtain a product of any required gravity. A copy of this chart will be sent on application to the Bureau of Mines, Washington, D. C.

Dr. F. G. Cottrell Succeeds Dr. Manning as Director, Bureau of Mines

THE resignation of Van H. Manning as director of the Bureau of Mines was not unexpected. It has been an open secret for several months that he would be selected as director of the research work of the American Petroleum Institute. Since it became known that Dr. Manning was about to resign there has been some agitation for the filling of the place with a mining engineer. Despite the very generally expressed preference for a mining engineer, the announcement that Dr. Frederick G. Cottrell, a chemist, had been recommended for the place brought forth no opposition. Dr. Cottrell's high professional standing and the fact that he has been in such close touch with the mining industry for so many years assure him of every confidence on the part of the mining industry. Dr. Cottrell was born in Oakland, Cal., Jan. 10, 1877. He attended school in Oakland and matriculated at the University of California in 1892. As a university student he gave especial attention to science, particularly chemistry. After graduation, in 1896, with the degree of Bachelor of Science, he was a Le Conte fellow at the university in 1896-7 and taught chemistry at the Oakland High School in 1897-1900. Then he went to Europe, where in 1901 and 1902 he studied at the University of Berlin and the University of Leipzig, receiving from the latter the degrees of Master of Arts and Doctor of Philosophy, 1902. On his return to this country, in 1902, he was appointed instructor in physical chemistry at the University of California, and in 1906 was appointed assistant professor, holding this position until 1911. While at the university Dr. Cottrell's chief contributions to science were researches relating to the electrical precipitation of fume and fine particles suspended in the gases of smelter, blast-furnace or cement works flues, and he finally evolved what is known as the Cottrell process for this purpose. This invention was first utilized at the Selby smelter in California for removing fumes from the waste gases of a sulphuric acid plant at the smelter, thereby abating a nuisance that threatened to necessitate shutting down the works. Subsequently this electrical precipitation process was installed at other smelters to remove fume and solid particles contained in the escaping gases, and it was also successfully used at cement plants, notably near Riverside, Cal., to prevent the dust from the calcining kilns from damaging nearby orange groves and vegetation.

DR. FREDERICK G. COTTRELL

Today the Cottrell process of fume and dust removal is in world-wide use, and is recovering materials heretofore wasted to the value of many thousands of dollars. One of the latest installations is at a large smelting plant in Japan; while the largest installation is at the Anaconda smelter, Anaconda, Mont. Dr. Cottrell in a desire to encourage scientific research turned over his extensive patent rights to a non-dividend-paying corporation, known as the Research Corporation, a body formed for that purpose. A fundamental requirement in the incorporation is that all net profits shall be devoted to the interests of scientific research.

In 1911 when Dr. J. A. Holmes, the first director of the Bureau of Mines, was serving as a member of commissions appointed by the Government to study alleged damages from smoke and fumes from the Selby and the Anaconda smelters, and when the Bureau of Mines was investigating at length the smelter-smoke problem, Dr. Cottrell, because of his scientific attainments and his special knowledge of metallurgical problems, was appointed chief physical chemist in the Bureau. In 1914 he was appointed chief chemist, in 1916 chief metallurgist, and in 1919 assistant director. Aside from his work on smelter smoke Dr. Cottrell has been deeply interested in and intimately connected with work on the separation and purification of gases by liquefication and fractional distillation. During the World War and subsequently the development of the Norton or Bureau of Mines process for the recovery of helium from natural gas has been his special care, and it was chiefly through his efforts that a plant for recovering helium on a large scale for military aëronautics has been erected near Petrolia, Tex. Dr. Cottrell is a member of the American Chemical Society, the Mining and Metallurgical Society of America, the American Electrochemical Society and the American Institute of Mining and Metallurgical Engineers. He was awarded the Perkin Medal by the New York Section of the Society of Chemical Industry in 1919 in recognition of his work on electrical precipitation.

Dr. Manning Deplores Inadequate Compensation

In his letter of resignation Dr. Manning says:

"In leaving the Government service there comes to me, as it has over and over again, the thought that although this Government spends each year many millions of dollars in useful scientific work for the benefit of the whole people, the monetary recognition of its scientific and technical servants is not sufficient to enable them to continue in the service for the people.

"With the marvelous expansion of the industry in this country and the growing necessity of science to industry, the scientific bureaus have been utterly unable to hold their assistants against the competition of industry which is taking their highly trained men at salaries the Government does not pay or even approach. I feel very deeply that there ought to be more adequate compensation for the scientific and technical men in the Government service so that none of them may be compelled to accept positions on the outside. Many of these scientific men are of fine type for Government work, care little for the commercial field, take an intense professional interest in their tasks and are of inestimable value to the Government."

Pre-War Legislation Affecting Nitrate Plants

Facts Concerning Political Activities in Congress—du Pont Co. Versus American Cyanamid Co.—Debate in the House and Senate—Passage of Measure as Section of National Defense Act—Selection of Site and Process—U. S. Nitrate Plant No. 1

By CHESTER H. JONES

A CAREFUL review of the *Congressional Record* covering the 64th and 65th Congresses beginning March 15, 1916, and of the more recent testimony delivered before the Graham House committee, 66th Congress, answers many of the questions which have arisen concerning the political motives behind the nitrate situation, and causes new queries to arise in the mind of the investigator. Some of these must for the time being remain unanswered.

Nitrogen fixation from the beginning was linked with the idea of water-power development, probably because cheap power was found to be essential to the success of the arc process in Europe. The cyanamide process also required a considerable quantity of power. It is a singular fact, however, that not a pound of nitrogen was fixed by water power in the United States during the war period. Indeed, plans were consummated to operate the large plant at Muscle Shoals entirely by steam power, and for this purpose the steam plants on the Warrior River (30,000 kw.) and the equipment at the cyanamide plant (60,000 kw.) were installed by the Government, together with an eighty-mile transmission line. The work on the Wilson dam was temporarily abandoned. It is now considered essential to complete the dam in order to make the process plant a commercial success.

In his recent testimony before the Graham House committee, Frank S. Washburn, president of the American Cyanamid Co., said that he was first interested in water-power development in the Southern district and therefore went abroad in 1907 to find an industry which would be a large consumer of power, thus building up the load on his proposed power plants. He returned with the cyanamide process for nitrogen fixation, but was forced to install his plant at Niagara Falls on the Canadian side because of political conditions unfavorable to the release of water-power sites in the United States.

Du Pont Proposals

The main controversy over nitrogen fixation opened in the Senate March 30, 1916, when Willard Saulsbury (Delaware) introduced bill S. 5,136 together with letters addressed to the Secretary of War and himself by Pierre S. du Pont, president of E. I. du Pont de Nemours & Co. These letters and bill contained a proposal whereby the du Pont company stood ready to negotiate a contract with the Government under which it would begin at once to construct a fixation plant in units of such magnitude as might be agreed upon by the Government, and the du Pont company would furnish the capital.

All the company asked was the release of water-power sites for the purpose. The bill provided "that at all times upon request of the Secretary of War the grantee shall deliver to the United States for military or naval purposes all or any part of the output of nitric acid at a price which shall include such profit as the Secretary of War shall determine to be reasonable, and his determination of the reasonableness of such profit shall be final."

An impartial study of the text of this bill and the accompanying letters discloses no ulterior motives such as were subsequently hinted at by political factions. The proposition seems clearly outlined and open. It was made by a reputable concern familiar with the Government methods of doing business.

Previous to the introduction of the above bill E. D. Smith (South Carolina) had introduced bill S. 4,971, which was at this time being considered by the Senate Committee on Agriculture. The committee had amended and was about ready to return it to the Senate. The Smith bill provided that the Government furnish the capital to build the necessary fixation plants. Upon the presentation of the du Pont bill, William S. Kenyon (Iowa) immediately recommended that the two bills be published side by side in the *Congressional Record*, and this was done.

Support of the Smith Bill

Oscar W. Underwood (Alabama) called attention to the fact that the du Pont company was a private corporation and spoke at great length against private ownership. He called attention to President Taft's veto of the Coosa River project, which had forced the American Cyanamid Co. to build in Canada some years previously. "Next to defending the country against a foreign enemy," he said, "the development of the agricultural interests is most important." He introduced clippings from the newspapers in which the du Pont company was criticized, and read into the *Record* an article by Frank S. Washburn, "one of the great engineers of this country." Mr. Washburn's paper appears on page 5,153 of the *Congressional Record*, 64th Congress. Mr. Underwood was the chief speaker for the advancement of the American Cyanamid Co.'s interests throughout the controversy, as evidenced by this and subsequent speeches.

Mr. Smith (South Carolina) urged that his bill be acted upon. He quoted Mr. Washburn, president of the American Cyanamid Co., as to the practicability of the cyanamide process, and said the Committee on Agriculture had interviewed Mr. Washburn and found he practically controlled the patents on manufacture by this method.

Opposition to the Smith Bill

Thomas W. Hardwick (Georgia) opposed Government ownership as outlined in the bill, calling the whole procedure "socialism." He continued in this attitude as a matter of principle in all his subsequent speeches.

Henry C. Lodge (Massachusetts) spoke in part as follows:

"The argument is not whether a corporation is back of a certain movement or not. I suppose a corporation is wicked in Pennsylvania or Delaware and good in Alabama. We should know who is behind these propositions.

"Frank S. Washburn is a patriot, no doubt, but it occurred to me we might find out what his business interests are. It appears in Moody's Manual that he is president of the American Cyanamid Co., which has been manufacturing this fertilizer for some years; that he is a director of the Alabama Traction, Light & Power Co., once president of the Muscle Shoals Hydro-electric Power Co., and other companies which control nearly all the water powers in Alabama.

"Mr. Washburn is associated with James B. Duke, tobacco manufacturer, and through Mr. Duke the American Cyanamid Co. controls the Ammo-Phos Co. of New York, the Amalgamated Phosphate Co. and the Virginia Chemical Co., which companies in turn practically control the fertilizer and cottonseed oil business of the territory east of the Mississippi and large water-power interests in North and South Carolina.[1]

"This development was proposed as early as January, 1909. Now I have given [these details] at somewhat tedious length because they all seem to be connected with Mr. Washburn, whose pamphlet has been sent to us to give the facts in the nitrogen case."

Mr. Kenyon (Iowa) suggested an investigation of the various processes for nitrogen fixation. He showed J. W. Worthington's political activities in Florence, Ala., on the Muscle Shoals development and his corporation connections with Mr. Washburn. The Engineers Corps had previously made an estimate of $18,500,000 for a dam at Muscle Shoals, exclusive of equipment. The Government had granted Mr. Washburn a monopoly through his patents, over 100 claims being allowed. On March 16 and 17 he had admitted before the Committee on Agriculture that he and Worthington had worked in the interest of the bill. "We might as well write Muscle Shoals in the bill and be done with it," said Mr. Kenyon.

Underwood Amendment

Mr. Underwood replied to these criticisms in a long speech (page 5,647, *Congressional Record*). He referred to Mr. Washburn as "a great hydro-electric engineer, a man of great ability," and asked for the support of the Smith bill. In a later speech, April 12, 1916, he offered an amendment authorizing and directing the Secretary of War to make contract with the owners for the use, rental, lease or purchase of a suitable air nitrogen process and further authorizing him to lease the plant for fertilizer manufacture in peace time.

Mr. Hardwick (Georgia) spoke at length, calling Mr. Underwood a "socialist," upon which the latter replied that his purpose was to make nitric acid and not fertilizer.

The debate was continued over a period of three days, during which time evidence was submitted on both sides by various Senators. Dr. Leo Baekeland's article on nitrogen was printed in the *Record*. The opposition led by Mr. Kenyon (Iowa) argued against the amendment.

Mr. Kenyon said: "The Underwood amendment if it is adopted will provide for the Government furnishing the money and building the plant, then leasing it to private parties. I cannot vote for this amendment nor the bill to which it is attached."

Mr. Lodge urged against placing so much power in Mr. Washburn's hands.

The amendment was finally rejected on vote.

Disposal of the Smith Bill

During the later discussions on the Smith bill it was shown that the constitutionality of such legislation might be in question on the ground of Government ownership in peace time. The bill was indefinitely postponed at the close of the 64th Congress, Third Session. This document was, however, so similar to the measure which finally passed that the discussion on the whole subject was not reopened on the later issue. The foregoing therefore represents the attitude of those concerned with nitrogen fixation in the Senate.

Debate in the Lower House

The controversy in the House of Representatives appears to have been opened March 17, 1916, when James Frear (Wisconsin) called attention to the clause in an Army bill which authorized the erection of nitric plants. He said: "Why was this slipped into the Army bill after it had been proposed in the Navy bill, authorizing the expenditure of $24,000,000 in Alabama Power Co. holdings? Apparently the Government is being used to finance this company's projects. It is a five-line section costing the Government over $4,000,000 per line. Why give $24,000,000 to Mr. Washburn's experiment?" He quoted L. L. Somers, C. W. Bennett, Joseph W. Richards and other experts who differed with Mr. Washburn's statements on the cyanamide process. He further found that 58 per cent of the American Cyanamid Co.'s assets were propaganda and patent rights, as shown by the 1914 report of the company as follows:

Total assets	$6,563,510
License, patents and patent rights	3,569,578
Founding and propaganda	230,589

Mr. Frear continued: "The Duke interests are reported to control the best phosphate deposits of the country and, connected with Washburn, make a promising fertilizer monopoly. This is the old Muscle Shoals project in a new garb. The Alabama Power Co. owns parcels of land along the river. This section should be stricken from the bill." Five exhibits were presented (page 4,324, *Congressional Record*) showing the Alabama Power Co. and Duke activities, in the newspaper clippings.

Nitrate Section in the National Defense Act

The important legislation in the House was contained in H.R. 12,766, Sec. 124, referring to the establishment of Government-owned nitrate plants. This section was essentially the same as the Smith bill in the Senate except it provided for the delegation of authority to the President instead of the Secretary of War. During the discussion Mr. Lenroot (Wisconsin) suggested that it be amended to give the power of its administration to the Secretary of War. Mr. Foster (Illinois) spoke in favor of Government-owned nitrate plants and was supported by Tribble (Georgia) and Sherley (Kentucky).

Mr. Ferris (Oklahoma) said on May 8, 1916: "Du Pont and other ammunition companies are meddling too much in the Government affairs. I am in favor of the Government-owned plant. The Senate amendment (Un-

[1] See p. 5,641 of the *Congressional Record*, 64th Congress, for details of all these interlocking interests in the fertilizer industry.

derwood amendment to Smith bill) will give all the surplus power to the American Cyanamid Co., and they in turn will sell it to the farmer at their own sweet price."

Mr. Miller (Delaware) defended the du Pont position. Other members of the House spoke in support of the nitrate provision, with Mr. Hulbert (New York), who demanded public hearings on the facts before the money was expended.

National Defense Bill Becomes a Law

The nitrate provision was finally carried through in Sec. 124, H.R. 12,766, National Defense, and became a law June 3, 1916, as recorded on page 215, vol. 39, part 1, Public Laws. Public 85. It reads as follows:

> Sec. 124. *Nitrate Supply.*—The President of the United States is hereby authorized and empowered to make, or cause to be made, such investigation as in his judgment is necessary to determine the best, cheapest and most available means for the production of nitrates and other products for munitions of war and useful in the manufacture of fertilizers and other useful products by water power or any other power as in his judgment is best and cheapest to use and is hereby authorized and empowered to designate for the exclusive use of the United States if in his judgment such means is best and cheapest, such site or sites, upon any navigable or non-navigable river or rivers or upon the public lands as in his opinion will be necessary for carrying out the purpose of this act; and it is further authorized to construct, maintain and operate, at or on any site or sites so designated, dams, locks, improvements to navigation, power houses and other plants and equipment or other means than water power as in his judgment is best and cheapest, necessary or convenient, for the generation of electrical or other power and for production of nitrates or other products needed for munitions of war and useful in the manufacture of fertilizers and other useful products.
>
> The President is authorized to lease, purchase or acquire, by condemnation, gift, grant or devise, such lands and rights of way as may be necessary for the construction and operation of such plants and to take from any lands of the United States or to purchase or acquire by condemnation materials, minerals and processes, patented or otherwise, necessary for the construction and operation of such plants and for the manufacture of such products.
>
> The products of such plants shall be used by the President for military and naval purposes to the extent that he may deem necessary, and any surplus which he shall determine is not required shall be sold and disposed of by him under such regulations as he may prescribe.
>
> The President is hereby authorized and empowered to employ such officers, agents or agencies as may be in his discretion necessary to enable him to carry out the purposes herein specified, and to authorize and require such officers, agents or agencies to perform any and all the duties imposed upon him by the provisions thereof.
>
> The sum of $20,000,000 is hereby appropriated, out of any moneys in the Treasury not otherwise appropriated, available until expended, to enable the President of the United States to carry out the purposes herein provided for.
>
> The plant or plants provided for under this act shall be constructed and operated solely by the Government and not in conjunction with any other industry or enterprise carried on by private capital.
>
> In order to raise the moneys appropriated by this act and necessary to carry its provisions into effect, the Secretary of the Treasury, upon request of the President of the United States, may issue and sell, or use for such purpose or construction, hereinabove authorized, any of the bonds of the United States now available in the Treasury of the United States, under the act of Aug. 5, 1909, the act of Feb. 4, 1910, and the act of March 2, 1911, relating to the issue of bonds for the Panama Canal to a total amount not to exceed $20,000,000: *Provided*, that any Panama Canal bonds issued and sold or used under the provisions of this section may be made payable at such time after issue as the Secretary of the Treasury, in his discretion, may deem advisable, and fix instead of fifty years after date of issue as is said in the act of Aug. 5, 1909, not exceeding fifty years.

In spite of all the opposition, and with all the evidence presented which questioned the motives of its supporters, the nitrate measure became a law. Its passage through Congress was facilitated by the immediate necessity for national preparedness, by the fact that it was of Democratic origin and that the promoters held the control of the only process which was commercially successful in this country at that time. A complete review of all the legislation on the subject is available in the testimony of George Walter Johnson before the Graham House committee published in the hearings Serial 6, Part 50, Jan. 2, 1920, beginning on page 2,537.

Selection of Site

Newton Baker testified that shortly after the act was passed, with its provision for an investigation of sources of power and processes of manufacture, the President appointed the Secretary of the Interior, the Secretary of Agriculture and the Secretary of War as a delegation to go about through the South and see where a proper site could be found for the building of a plant for the production of nitrates in war time and fertilizer in peace time. This trip was made in March, 1917, in company with a party of nitrogen-fixation experts, including Colonel Wheeler and Dr. Charles L. Parsons. They visited points in Tennessee, Kentucky and West Virginia. They never visited Western points, but intended to do so.

Some time after the return from this trip the three Secretaries discussed the matter informally, and Mr. Baker talked it over with the Chief of Engineers and the Chief of Ordnance. The latter, supported by other members of the party, submitted the following recommendations:

> I think that the examinations made indicate the limit of choice to four localities, viz.: Chattanooga, Knoxville, Sheffield and North Birmingham, and after fully considering all the aspects of the matter, it is my opinion that the site at North Chattanooga, Tenn., having been adjudged first from the fertilizer standpoint and next from the compromise standpoint, is best fitted for the constructions now contemplated, and I recommend its adoption, and the purchase of a tract of 500 to 600 acres.
>
> William Crozier,
> Brigadier General, Chief of Ordnance, United States Army.

On the margin of that memorandum dated Aug. 6, 1917, is a postscript, or a sort of note:

> The original letter 471, 86/2020—Nitrogen, j/z. dated Sept. 20, 1917, a memorandum for the Secretary of War, signed by William Crozier, Brigadier General, Chief of Ordnance, United States Army, copy of which you already have been furnished; bears the following postscript in long-hand:
>
> "The President has selected Sheffield. So informed by Secretary of War.
> 9/28. W. C."

It is understood that the department heads indorsed this recommendation to the President, but he decided on the Sheffield, or Muscle Shoals, location in spite of such advice. The authority was vested in the President according to the provisions of the law, and he was evidently persuaded by advisers not members of the delegation which had been charged with recommending a proper site.

Selection of the Process

During the time that the site was under discussion, the committee of the National Academy of Science was

investigating the matter of processes, having made a trip to Europe for the purpose. Other commissions and individuals were carrying on similar inquiries.

Appointed by General Crozier to visit Europe in 1916, Dr. Charles L. Parsons studied processes in England, France, Italy and Greece and made an individual report which did not agree with the report made by the National Academy committee, in that he strongly favored the synthetic ammonia or modified Haber process of the General Chemical Co.

The Secretary of War then appointed a new committee called the Nitrate Supply Committee, and made Dr. Parsons a member. The personnel of this committee was as follows:

General William Crozier, Chief of Ordinance, U. S. Army; Admiral Ralph Earle, U. S. Navy; General William Black, Chief of Engineers, U. S. Army; F. W. Brown, U. S. Dept. of Agriculture; Dr. Leo H. Baekeland, Gano Dunn, Dr. Charles H. Herty, Dr. William F. Hillebrand, U. S. Bureau of Standards; Dr. Arthur A. Noyes, Dr. Charles L. Parsons, Dr. Willis R. Whitney.

This committee recommended, among other things, that the Government negotiate with the General Chemical Co. for the right to use the synthetic process for making ammonia, erect a plant to produce thirty tons of ammonia per day and an auxiliary plant to oxidize the ammonia to nitric acid.

U. S. Nitrate Plant No. 1

Contract was made with the General Chemical Co. as advisory engineer, on the modified Haber process, with the J. G. White Engineering Corporation as construction engineer to undertake the erection of the plant and with the Chemical Construction Co. to construct the special apparatus in the nitric acid plant. Thus the work on U. S. Nitrate Plant No. 1 at Sheffield, Ala., was finally started, during August, 1917.

Political Comment

On Sept. 14, 1917, Nicholas Longworth (Ohio) spoke in the House of Representatives concerning the report of the Nitrate Supply Committee mentioned above, quoting Dr. Herty as stating, "The country will receive supplies of fixed nitrogen far more quickly than possible under the methods which would require time in the development of water power." Mr. Longworth adds: "I was opposed to the $20,000,000 nitrate scheme because it involved only one plant. On report of Dr. Parsons, General Crozier and others it has been decided to indefinitely postpone making nitrogen by water power. This, thank goodness, sounds the death knell of the Muscle Shoals nitrate scheme. Its abettors and supporters have been knocking at the doors of Congress for some years."

Conclusion

It is not within the scope of this article to give more than a brief outline or series of sidelights from the history of the circumstances surrounding so wide a subject. Many inferences may be drawn from thorough research in the available archives to suit the taste of the individual explorer. No one can deny that with the present knowledge of the case at hand many humorous things are to be found in so reviewing.

It is the story of political intrigue, with the ever-present private interests in the near background; of sectional preference, with the needs of the nation often a secondary consideration, and differences of opinion held by scientists on a comparatively new subject. It may be gathered from the above paragraphs that Mr. Underwood is the gentleman from Alabama who helped do things for his state; that Mr. Longworth is from Ohio, not Alabama; that Mr. Washburn is in the fertilizer business; that Dr. Parsons is a strong advocate of the synthetic ammonia process; that the President ignored his official advisers, and many other pertinent facts which will make the readers of Chemical & Metallurgical Engineering better acquainted with the gentlemen who will have something to say when the pending bills for the operation of the Government plants are returned to Congress from the committees.

In the days of the war when these things were carried on, there was no question as to the earnest effort of the principals to accomplish those objects which would be of greatest benefit to the nation. Beneath it all lay a sound economic theme, and because the country needed nitrates in war and peace alike the deed was consummated. Because of patriotic fervor it was done quickly and successfully. The equipment stands idle today awaiting the action of Congress to start its operation in the service of agriculture.

Use of Cibucao Wood for Dye in Hongkong

The business of the import of "cibucao" wood from the Philippines and its manufacture into a stain or dye in Hongkong is in the control of a close combination of five Chinese firms in Hongkong, of which Yuet Loong Chan & Co., Hongkong, is the principal. The wood, called "Soo Mook" in Chinese, comes almost exclusively from Iloilo and vicinity in the Philippines. It is a red, fairly soft wood, and is cut and cured in short lengths and imported in bundles. It is bought and sold by the picul (133⅓ lb.), its price in Hongkong at the present time being about $2.10 local currency, or substantially the same in gold, per picul. The stain or dye manufactured from the wood is a red ink or paste used largely by the Chinese for inking the small "chops" or seals employed by them as the means of affixing their signatures to written instruments of a formal nature.

The color in the wood is extracted and used variously by the Chinese as an ink, a stain, dye, and paint color. The wood is boiled and the resulting water solution is further boiled down to a siruplike consistency. Whiting is then mixed with it for most purposes, the resulting paste being the preparation used as an ink for the native "chops." As a dye the stain is used for coloring cheap Chinese papers, notably the paper used in the manufacture of firecrackers, ceremonial papers of various sorts, and for the very cheapest sort of Chinese stationery. The whiting concentrate also is used as an adulterant for European red paints. The color liquor also is used at times for mixing with better quality of red dyes for coloring native cloths.

The whole process of extracting the dye is crude and wasteful, but the business is closely controlled by this syndicate, which is strong enough to regulate the volume of the manufacture and the price of the product. It is doubtful, therefore, whether it would be practicable to transfer the industry to the Philippines and have the dye or stain manufactured there for sale in China, although apparently there would be a considerable saving in freight and other expenses by so doing.

A Comparative Test Upon High-Speed Steels—II

Conditions Entering Into the Testing of a Tool for Cutting, Listed by Taylor, Are Discussed—Detailed Information is Given as to the Method of Eliminating Most of the Variables From a Comparative Test for the Efficiency of Several Brands of Commercial Tool Steel*

BY A. J. LANGHAMMER, M.E.†

AS EVERYONE knows, the Packard Motor Car Co. was the pioneer manufacturer of Liberty airplane motors for the United States Government during the war. In building Liberty "12" airplane motors, one of the most intricate problems was that of machining the steel cylinders. At the start of the manufacturing program, this unit was made of a solid billet, which practice fortunately was rendered obsolete by the most opportune invention of the Ford Motor Co. The Ford method permitted the making of these cylinders from steel tubing at greatly reduced initial cost and with an additional huge saving in labor (boring of billet) and tool costs. The material used was heat-treated mild carbon steel, subjected to rigid Government inspection for both composition and physical properties before it entered the machine shop. The result was, therefore, a product of unusual uniformity, thereby furnishing a material of exceptional merit for testing purposes. Since it was not only essential to get a product of highest quality machined to extremely low tolerance and limits but it was also vital to obtain a maximum production of airplane engines, a test was decided upon to determine the high-speed steel which would meet these difficult requirements. The following pages describe that test in detail.

Elements Entering Into the Cutting of Metal

Dr. F. W. Taylor in his "Art of Cutting Metals" gives twelve elements that affect the cutting speed of tools. To this must be added one more, the human element, thoroughly recognized by Dr. Taylor but emphasized by Prof. A. L. Jenkins, professor of mechanical engineering at the University of Cincinnati. As every test of cutting tools that is to be of any value must take full cognizance of these elements, they are listed below in abbreviated form:

1. Quality of metal to be cut.
2. Chemical composition of the tool steel and its heat treatment.
3. Thickness of shaving (feed per revolution).
4. Shape or contour of cutting edge of tool.
5. Type of coolant (water, oil) used.
6. Depth of cut.
7. Duration or length of cut.
8. Lip and clearance angles.
9. Elasticity of the work and of the tool, i.e., degree of chattering.
10. Diameter of work.
11. The changes of speed and feed possible in the machine tool.
12. The pulling and feeding power of the machine tool.
13. Human element.

To simplify the test and make the results more positive, as many elements as possible were made constant. Each variable as it affected our test in accordance with the above classifications will be discussed briefly.

Cutting Speed

In determining the proper cutting speed,[1] the depth of cut, feed, and the machine tool flexibilities had to be considered most carefully. The depth of cut was first determined (see discussion under that heading below) and then with the aid of special tools, not included in the test proper, several runs were made and a cutting

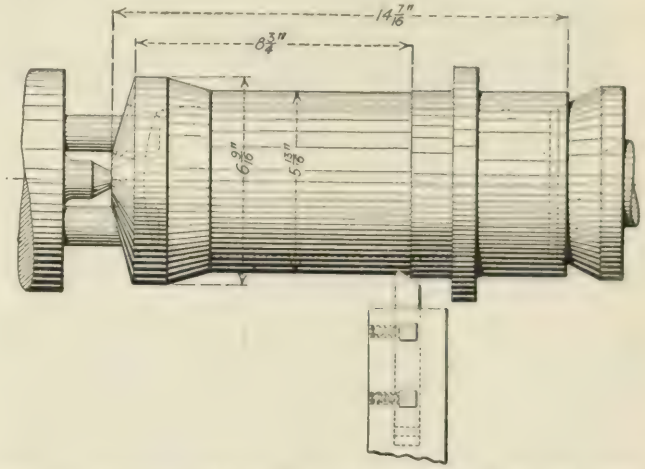

FIG. 1. SHOWING THE MATERIAL CUT AND SET-UP USED IN TESTS

speed of 35 ft. finally chosen. This value was used throughout the test in all runs and was maintained at a constant value, thereby eliminating the factor "cutting speed" as a variable.

Quality of Metal to Be Cut

The metal cut was the Liberty airplane motor cylinder, a mild carbon (0.40 to 0.50 per cent) heat-treated stock. Fig. 1 shows the cylinder in the rough before any machining operations have been performed. Every cylinder used in the test had to show a hardness between 217 to 255 Brinell (scleroscope 36 to 43) before it was accepted by Government inspectors. As there were thousands of cylinders to choose from, only those were actually selected for test purposes whose scleroscope range did not exceed these points. Each cylinder was also carefully inspected for out-of-round, eccentricity, variations in diameter, fins, and excessive scales or rust formations, any unsatisfactory specimen being summarily rejected. Attention is invited to these exceptional conditions by which the test was favored because such a desirable material would hardly be found avail-

TABLE II. COMPOSITION AND HEAT TREATMENTS OF TOOL STEELS TESTED

Brand	Chemical Composition * Carbon	Tungsten	Vanadium	Nickel	Chromium	Cobalt	Uranium	Heat Treatment: Preheating	Hardening	Quenching Medium	Drawing Temperature	Remarks on Heat Treatment
A	0.79	12.8	1.74	0.10	3.78	None	None	All tools slowly preheated to 1550-1600 F.	The temperature in the hardening furnace was maintained at practically 2300 F. The tools were withdrawn and quenched when the condition of sweating was satisfactory to the expert representing the steel company which produced the brand being hardened.	Oil	1050	Cyanide on tip of tools during hardening.
B	0.64	16.9	0.92	0.10	2.42	None	None			Lead at 1050 F.	1100	"B" tools withstood the high heat very well.
C	0.40	18.00	0.51	Tr.	3.53	None	0.11			Lead and kerosene.	1050	Tools 0 and 1 quenched in lead. Tools 2 and 3 quenched in kerosene
D	0.62	14.86	1.05	Tr.	3.59	None	0.10			Lead at 1050 F.	1100	One-half of tool immersed in lead. Relatively short heat.
E	0.49	17.35	0.23	Tr.	2.78	None	0.14			Lead	1100	
F†	0.67	19.70	0.99	0.21	3.78	None	None			Oil and lead	1100	Tools 0 and 1 quenched in lead. Tools 2 and 3 quenched in oil.
..	0.65	15.79	0.49	0.24	3.44	None	None					
G	0.62	18.26	0.75	Tr.	3.70	None	None			Oil	1050	
H	0.66	18.30	0.45	None	4.17	None	None			Lead at 1050 F.	1075	
J	0.68	18.12	0.48	Tr.	2.63	None	0.10			Oil and lead	1050	Tools 0 and 3 were immersed half way in oil; then they were placed on the floor and thus drawn.
K	0.59	13.34	0.95	Tr.	3.64	None	0.15			Oil	1075	
L	0.76	21.92	1.05	None	5.27	None	None			Lead at 1050 F.	1050	
M	0.69	16.95	0.75	0.18	3.09	None	None			Oil and kerosene	1100	Tool 2 quenched in oil. Tools 0, 1 and 3 quenched in kerosene. "M" tools withstood the high heat very well.
N	0.66	13.55	2.20	0.10	3.59	None	None			Oil	1050	
O	0.67	13.50	0.99	0.20	4.30	None	None			Oil and lead	1100	For tool 0 only. Tools 1, 2 and 3 were not drawn.
P	0.38	15.27	0.05	0.20	2.85	None	0.14			Lead	1100	Blistered on heating.
R	0.65	17.08	0.58	0.20	2.78	None	0.10			Oil and lead	1075	Tools 0 and 2 were quenched in lead. Tools 1 and 3 were quenched in oil.
13, 14‡	0.75	11.12	2.10	0.32	5.13	None	None				None	

The samples for chemical analysis were obtained from the same section of the bar of which the tools were made.

The temperature of the lead bath used in quenching was maintained at a temperature of 1050 F. The tools were immersed in the molten metal for about 3 min., and then allowed to cool in the air.

* Phosphorus and sulphur below 0.04 per cent in all cases.
† The second analysis under F gives that of a second bar obtained subsequently.
‡ This steel was not tested, but its microstructure is shown in Figs. 13 and 14.

able in ordinary practice. The factor of "quality of metal to be cut" was perforce a constant.

As a matter of record the metal being cut may be noted to be the so-called "Aircraft Standard Steel," or S.A.E. 1045, known to the trade as 0.45 carbon machine steel. The chemical compositon is

	Per Cent
Carbon	0.40 to 0.50 (0.45 desired)
Manganese	0.50 to 0.80 (0.65 desired)
Phosphorus	0.045 maximum
Sulphur	0.05 maximum

Ordinary heat treatment given the forgings consisted of a quenching in oil or water from 1,500 to 1,550 deg. F. (820 to 845 deg. C.) and a drawing at 1,150 to 1,200 deg. F. (620 to 650 deg. C.).

After such treatment the physical properties were:

Elastic limit (approximately)	67,000 lb. per sq.in.
Tensile strength (approximately)	98,000 lb. per sq.in.
Elongation	20 per cent
Reduction of area	56 per cent

Chemical Composition of the Tool Steel and Its Heat Treatment

In the first few columns of Table II are given the chemical composition of each set of tools of the separate brands, as determined by actual analysis. This composition supposedly represented the standard practice of the steel manufacturer. If the company made more than one grade of high-speed steel, the best or "superior" grade only was specified, as will be pointed out in more detail in the next paper. The heat treatment of each tool likewise is shown in Table II. "Chemical composition" therefore was a variable.

Thickness of Shaving

Experience has taught that the finer feeds are not adapted to test work because slight imperfections either in the cutting edge of the tool or in the material cut affect the tool in a manner more disastrous than a coarse feed. In shop practice, too, medium or heavy feeds are generally used and if the test conditions approach normal practice the results can be more easily interpreted by shop men. A feed of 0.054 in. was used in our "first run" and 0.090 in. in the "second run." (See discussion below under "Methods of Procedure.") As each value of feed was adhered to throughout the individual runs the "thickness of shaving" was a constant.

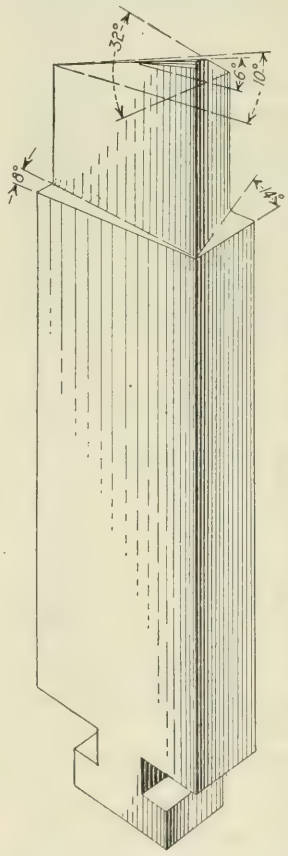

FIG. 2. LO-SWING LATHE TURNING TOOL

Shape or Contour of Cutting Edge of Tool

Fig. 2 shows the type of tool used in the test. Each individual tool was machined, rough ground and finish-ground. This particular design of tool is adaptable for a "Lo-Swing Lathe," because on such a machine the cut is generally started by "feeding in" the tool to the desired depth and then engaging the feed, rather than "setting" the tool to the desired depth before engaging the power feed. (See Fig. 1 for the illustration of this point.) Also on most work a "gang" of tools are used, some of which must cut right up to a shoulder or flange, necessitating the side cutting edge of the tool being parallel with the shank. All grinding was performed by an expert on a Taylor automatic tool grinder and every tool was inspected after the final operation.

A nose of $\frac{1}{16}$ in. radius or $\frac{1}{8}$ in. "rounding" was ground on all tools for the first run, while a $\frac{1}{8}$-in. radius or $\frac{1}{4}$-in. "rounding" was adopted during the second run. The radius was increased during the second run, because with the given designs of tool this procedure necessitated the minimum grinding and thereby reduced the chances of harming the tool during the grinding operation. As the stated values of the radii were uniform

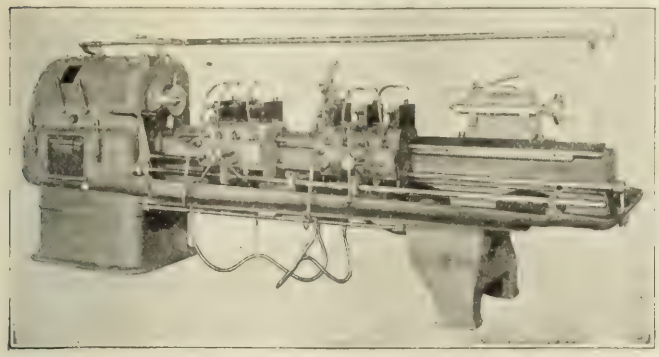

FIG. 3. TYPE OF MACHINE TOOL USED IN TESTS. EIGHT-INCH LO-SWING LATHE

for each run and the shape of the tool was rigidly inspected after grinding, the "shape or contour of cutting edge of the tool" was made constant.

Type of Coolant or Cutting Compound

The use of a coolant in itself introduces several variables (such as uniformity of material, pump trouble, misguidance of the cooling stream, etc.), adds considerably more work, and provides for possible inaccuracies. As it was desired to determine only the comparative life and not the maximum attainable, no coolant was used, thus making this factor, "type of coolant or cutting compound," zero.

Depth of Cut

Once either the feed or the depth of the cut has been decided upon, the other factor in conjunction with the cutting speed is determined by the time limit set for failure to occur, and by the power and flexibility of the machine tool employed. In this case the depth of cut was established first, because the material cut had to enter the regular production when the machine work was finished. This, then, limited the diameter to which the specimen could be reduced, and thereby automatically established the depth of cut, $\frac{3}{32}$ in. in this instance. The value of the depth of cut, like the feed, should in all cases approach the normal for ease of interpretation, and the figure stated checks very closely with the amount of stock removed in the average roughing operation on a simple drop forging. A snap or external limit gage that held the turned diameter to a variation of 0.005 in. was used to measure the depth of cut (the rough diameter of the material had been previously checked, as already described at length under "Quality of Metal to Be Cut"), so that the "depth of cut" was reduced to a constant.

Duration or Length of Cut

The duration of cut in a test on cutting tools is an item that requires very careful consideration. When too short a time limit is chosen, the results are questionable, if not valueless, because the heat generated at the working point of the tool is so great as to cause unjustifiable and wide variations in duration of cut. Too long a time is somewhat less objectionable, because it entails increased difficulties with respect to securing homogeneous material and possibly induces general inaccuracy. Therefore, for the first run, a duration of about 25 per cent less than the standard practice on that particular class of work was chosen. On the second run, however, a value which caused an average good tool (as determined by experiment with tools made up especially for this purpose) to fail within 20 min. was applied. Of course the time limit, other things being equal, depends on the cutting speed, feed, and depth of cut. As the depth of cut was predetermined due to the fact that the material used was a "production part" and the feeds and speeds of the machine tool used, an 8-in. Lo-Swing Lathe, Fig. 3, were limited, it was decided to change the feed only to vary our duration or length of cut. The element of "duration or length of cut" was perforce a variable.

Lip and Clearance Angles

At the beginning of the test the design of tool and all clearance angles were decided upon. The various clearances and slopes were as follows: 6 deg. clearance at the nose and 10 deg. clearance at the heel, 14 deg. side slope, no back slope, 32 deg. horizontal clearance, 8 deg. vertical clearance, 84 deg. lip angle and 90 deg. cutting angle. See Fig. 2 for a perspective representation of this tool and the values given. As these values were identical on each tool, the element of "lip and clearance angles" was of necessity a constant.

Elasticity of the Work and of the Tool, or Chattering

Chattering affects both the cutting-speed and finish of the work and is caused by incorrect design of cutting tool, incorrect method of clamping and driving the work, poor design and ill fits in the machine tool, synchronizing of the effects of defective elements and loose fittings in the machine and the set up, or a combination of these. By inspection of Fig. 2 it will be seen that the design of tool was such as would discourage chattering. In the same way Figs. 1 and 3 show an unusually rugged

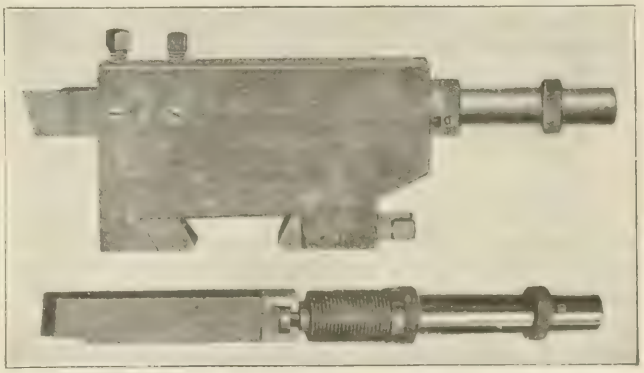

FIG. 4. DETAIL OF THE METHOD OF TOOL HOLDING, TOOL CLAMPING AND TOOL FEEDING

and positive drive with a good set up, so that chatter from this source was eliminated. Attention is invited to Fig. 4, which shows the particularly rugged tool block that was used. It is to be noticed that fully 80 per cent of the total length of the tool rests solidly on its base and that set screws are provided for securing absolute rigidity both horizontally and vertically. The choice of

machine tool provided a unit that was very adaptable to the work of the test, so that "chattering" as it affected the cut-speed was made a constant, approaching zero.

Diameter of Work

Under "Quality of Metal to Be Cut" it was pointed out above that all forgings were carefully inspected for variations in diameter. As a huge amount of stock was available, nothing but perfect specimens were accepted, so that the "diameter of work" was easily made a constant. This, too, was a feature that cannot easily be duplicated under ordinary conditions. Also the value of the diameter was such that it provided for easy interpretation in general shop practice.

Change of Speed and Feed Possible in the Machine Tool

In Fig. 3 is shown a half tone of the machine tool used in the test. The range of speeds and feeds are given in Table III.

TABLE III. CHARACTERISTICS OF MACHINE TOOLS USED

Spindle Speeds for 500 R.p.m. of Pulley	Feed per Revolution, Inches
25	0.166
45	0.120
75	0.090
120	0.054
200	0.040
325	0.030
	0.018
	0.013
	0.010

A belt- and not a motor-driven machine was used, so that the choice of feed and speed to secure failure of the tool within a given period was somewhat limited. By establishing the cut-speed and depth of cut at the onset, a proper feed was, however, readily determined so that the "change of speed and feed possible" was eliminated as a contending factor.

Pulling and Feeding Power of the Machine Tool

Inspection of Fig. 3 will show a lathe of rugged construction. The geared headstock is of good strength, and the heavy bed, carriage, and feed mechanism provide for rigid support and taking of heavy strains. As a matter of fact, the load applied in the test did not at any time approach the possible duty of the machine. The unit used was a new machine that had only been "limbered up" preparatory to the test. No variations were therefore introduced due to the "pulling and feeding power of the machine tool."

Human Element

It is generally conceded that in any undertaking the human element presents a very complex problem. This factor, therefore, received due attention and the personnel was made up not of one but of two operators who, in addition, were not only lathe hands but tool makers as well. Both men worked under constant supervision of a competent observer who was a technical graduate with years of practical experience. To further insure the accuracy of the test, other engineers checked the data and operations at frequent intervals so that the "human element" was made constant in so far as it was possible.

Variable Factors in the Tests

By a review of the above thirteen elements and the brief discussion of the manner in which they affected the test, it will be seen that only two—chemical composition of the tool, and duration or length of cut—remained variables. This condition, then, formed the basis of the test.

Duration of Test

Possibly it will occur to the reader to ask, "How long did it take to run this test?" To answer this the following data are submitted:

The time that elapsed from the date on which it was decided to run the test until the work was all completed and the data compiled was five months, in round figures. The actual number of cylinders turned with the test tools was 1,251 while another 150 were machined by special tools in determining the correct feed and duration of cut for the test proper. All told, then, 1,400 cylinders, or 1,690 ft. of 5¾-in. medium-carbon steel, were machined in this test.

(Part III will be published in our next issue.)

Belgian Penalties for Commercial Fraud

American manufacturers or exporters having trade disputes with Belgian importers should take note of the penal provisions of the Belgian code relating to obtaining money under false pretences. According to article 428 of the code, such false pretences connected with the sale of goods (*tromperie sur marchandises vendues*) are punishable by imprisonment of from one month to one year, or by fine of from 50 to 1,000 francs, or both. Fraudulent intent may arise from the furnishing of goods not of the quality or kind specified, or from deliberate failure to furnish specified quantities.

As *tromperie sur marchandises vendues* is a basis for criminal action, aggrieved Belgian importers have the right to cause the arrest of foreign vendors accused of such practices upon their arrival in Belgium. As there is no provision for release on bail pending trial in criminal cases, as in the United States, evidence of fradulent intent must be clearly shown by Belgian business men before a warrant is issued, however.

In a recent case a small and apparently irresponsible export house in New York had sold adulterated goods to several Belgian dealers. The importers had rejected the shipments when chemical analysis disclosed the adulteration and were attempting to secure reimbursement from the exporter. In the meantime one of the members of the exporting firm arrived in Brussels and was promptly threatened with summary arrest by his customers.

In this instance the export house claimed that the supplying manufacturer was responsible for the adulteration; it was also claimed that there was a misunderstanding regarding the nature and quantity of the goods, owing to ignorance of the French language. It was therefore impossible to establish prima facie fraud sufficient to justify imprisonment pending trial of the case. However, if the visitor to Belgium had been a manufacturer (not a forwarder) who had clearly furnished adulterated goods and received payment therefor, the result would no doubt have been more serious.

Polish Courts to Register American Firms

The Legation of Poland in Washington has received information from its government that courts in Poland have been instructed to register American firms without hindrance.

The Function of the Chemical Engineer in the Biscuit and Cracker Baking Industry

Application of Chemical and Industrial Engineering in the Baking Industry Is Now Recognized to Be a Really Great Step Toward Technical Improvements Leading to Uniformity of Products Manufactured and Efficiency of Plant Operation

BY O. C. F. LIPPERT
Chemical Engineer, the George H. Strietmann's Sons Co.

THE idea of having a chemical engineer associated with the organization of a biscuit and cracker bakery is a modern one. This is due to the fact that biscuit and cracker bakeries until recently have been rather successfully conducted by the "rule of thumb" methods.

The industry for the most part was made up of very small units in which it was possible for one or two men to successfully make and bake all the products by a sort of intuition, just as the housewife supplies the home with good bread and cake. That is, if she is asked to tell how she makes her products, she will somewhere in her instructions for making, or in her recipe, say: "I add so much of this or that until I get a certain taste," or else she will say: "I bake it until it gets such and such a color."

In a similar manner in the past and to some extent even today, the foremen of the various departments had and have that intuition which permits them to turn out a product which cannot be readily duplicated, even by their own assistants.

Chemical Engineering Work Needed to Obtain Uniformity in Manufactured Products

When one of these small units reaches a certain size, it becomes necessary that the products which the firm produces maintain a certain standard. Unfortunately it becomes impossible to maintain this standard when the responsible foreman is incapacitated. This is disastrous to the marketing and sale of the product and so the slogan of the sales department is "Uniformity." In the home or smaller concerns the problem would be met by waiting until the return of the party with the "gifted or inspired method of procedure." Where the units or plants are large, it is readily admitted that this is entirely impractical. Accordingly it becomes necessary to devise means and methods to bring about this uniformity. In this connection the services of a chemical engineer are most valuable, as his training, devoted to the study of materials and to methods of manufacture, fits him for undertaking work of this nature.

His work almost automatically divides itself into three main divisions which may be characterized as studies of (*a*) raw materials, (*b*) methods of manufacture, (*c*) finished products and industrial engineering.

Raw Materials

The problem of studying raw materials as used in the baking industry with reference to uniformity is complex. There is probably no industry which uses so many varieties of raw materials in so many combinations. Also, the raw materials are, for the most part, organic in nature and complex in structure, as the following list will show: Flour, butter, lard, shorteners, vanilla and flavoring extracts, eggs, milk, sugar and others. The inorganic raw materials, such as salt, sodium bicarbonate, do not present any difficulties. However, ammonium carbonate, the associate of sodium bicarbonate as to functioning, has presented rather interesting studies from time to time owing to its complex nature.

Methods of Manufacture

Topics in this group are:

1. The proper sequence of raw materials in mixing.
2. The physical condition of the raw materials before mixing.
3. The manner of mixing.
4. The conditioning or aging of the mix.
5. The treatment or preparation of the dough for the cutting machine.
6. The quantity of heat used.
7. The quality of heat used (including kind and temperature).
8. The method of baking (whether directly on the ovenpans, or on wire mesh pans, or on separate greased pans).
9. The subsequent cooling of the product.
10. The time elapsed from leaving oven until in container.

Not every problem required a study of all of the above topics, but all required taking into consideration at least the greater number of them.

Finished Products and Industrial Engineering

Concomitant with methods of manufacture, problems of industrial engineering are met with such as:

1. Time and motion studies of operations.
2. Stock arrangements.
3. Routing of materials (both raw and finished).
4. Costs and production.
5. Mechanical problems of equipment.

Typical Analyses Needed in the Baking Industry

In order to give some idea as to the nature of the raw materials studies, the following is presented.

The main raw material used in the baking industry is flour, which is supplied in sacks of 98 lb. and 140 lb. (usually the latter). It is stored on platforms or trucks, twenty-one sacks to a platform in layers of three sacks each. The problem of getting representative samples and keeping track of the various lots as received and analyzed was rather annoying, as it was of little importance to the stores department workmen to keep supplies according to lots. It was met by tagging each platform with a serial number and using the well-known butter or lard "trier" or "thief." It was found that the

trier gave a conical sample extending from the outside of the sack to the inside or center. In this way, the sample contained flour which had been subjected to atmospheric conditions as well as flour which had been protected from same. By taking samples from several sacks in proportion to the size of the lot of flour and mixing these sack samples, a very representative lot sample was obtained.

The next problem was, What kind of analysis should the flour be subjected to, consistent with time, cost and results?

The following analyses are typical of flour as used in the baking industry and as submitted by wheat and flour-testing laboratories:

	Straight Per Cent	Patent Per Cent	Patent Per Cent
Moisture	12.50	11.18	11.70
Fat or oil	1.12	0.98	1.35
Ash	0.564	0.508	0.488
Absorption	57.00	56.00	56.55
Color	100.00	104.00	101.00
Gluten (dry)	8.38	9.49	10.36
Protein (5.7 × N)	9.22	10.28	11.55
Quality of gluten	100.00	94.70	101.50

Sometimes the additional information of loaf value (expressed in per cent) is given.

Critical Study of the Analyses for Use in the Cracker-Baking Industry

A critical study of the analyses for use in the cracker-baking industry as to the importance of the individual items, consistent with time, cost and results, led to the following conclusions:

1. That the moisture, gluten, absorption, protein and ash determinations were worth the time and cost.
2. That the fat determination was not worth the time and cost.
3. That the loaf value was not directly applicable in the cracker and cake industry and hence not worth the time consumed in obtaining it.
4. That the color and quality of gluten determinations were of some value.
5. That some supplemental test or determination would have to be made which would give the same information to the cracker baker about the quality of gluten that the loaf value does to the bread baker.
6. That this test must be carried out in conjunction with some of the other tests.

The bread baker bakes one kind of product—that is, he bakes different kinds of bread—but he is not using his flour in as many different formulas nor is he using it with as many kinds of ingredients.

Importance of Determining the Value of Gluten and the Method of Its Determination

The problem narrowed down to determining the value of gluten as gluten alone and the effect of heat on the gluten, i.e., of determining what was afterward called the expansion test.

At the present time no method is known by which proteins or gluten may be isolated by chemical methods. However, the physical method, of washing out the starchy part of flour, is very applicable, especially so since it can be carried out with rapidity. Furthermore, the absorption value can be previously determined and subsequently the appearance and elasticity of the gluten noted and examined on the same sample.

The method of procedure for obtaining the absorption value and washing out of the starchy material is as follows: 33.33 g. of flour is weighed into a beaker and 15 c.c. of cooled distilled water is added from a burette. It must be remembered in connection with the washing out of the starch that the temperature of the water is of importance, i.e., must be kept cool. Then ½ c.c. of water at a time is added until a dough of proper consistency is formed. The number of c.c. of water used multiplied by 3 equals the absorption of the flour for water.

Enough water is now added to cover the dough and same set aside for 1 hr., after which it is washed out over a screen of bolting cloth, using cooled (in summer cold) water, until free from starchy material. Care must be exercised not to have the water flowing too fast, as it tends to divide the gluten into small particles which are hard to incorporate with the main portion. Care must also be taken not to extend the washing-out process over too long a period of time, as this causes the gluten to adhere to the fingers. Any loose or small pieces of gluten which have been caught on the bolting cloth screen can be gathered by using the main ball as a swab. The screen is made by fastening silk bolting cloth (125 mesh to the lineal inch) into the largest size obtainable embroidery frame. The gluten thus gathered into one ball is put in a beaker using fresh cooled water and allowed to stand for an hour, after which it is observed as to its elasticity and quality, which are determined by physical examination.

Glutens of excellent quality will have a light or creamy color, will remain solid and will be elastic. There is, however, a difference in the elasticity of excellent quality gluten. Some stretch very readily without breaking, while others offer more resistance. This aids in a preliminary way in determining the use of a flour, i.e., whether it is adapted for crackers or cakes.

Method of Determining the Heat Action on Gluten

The following method was developed in determining the heat action on gluten and has been termed the "expansion test": The moisture from the isolated gluten is removed by pressing the gluten between the palms of the hands and the fleshy part of the thumb. Care must be taken to have the hands cool (which is usually accomplished by allowing water to run over the wrists). The hands must be frequently dried during this operation. The gluten is then rolled into a ball and transferred to a clean, previously weighed, zinc plate about 2 in. square, which is then placed in an electrically heated oven or furnace, where a temperature of 158 to 160 deg. C. is maintained for 18 min. At this temperature and for this time the best expansion of the gluten is obtained. It is then transferred to a drying oven maintained at 100 deg. C. for a period of 16 hr. (usually over night), then weighed and dried to a constant weight at hourly intervals. It has been found that all the moisture has been expelled in the 16-hr. period when the test is conducted as above.

The measuring of the expansion is accomplished as follows: The gluten ball is carefully removed from the zinc plate (zinc plates are used because the adhesion of gluten to zinc is less than in the case of other metals or glass) and placed in a 2½-in. cubical measuring box with sliding lid. Seeds of fair size (such as hemp) are added (from a graduated cylinder filled with the seed and whose cubical contents equal that of the box) until the box is filled. The seeds remaining in the cylinder give the cubical contents of the volume occupied by the gluten ball. The volume thus obtained, divided by the number of grams of dried gluten, equals the expan-

sion per gram of gluten, which when multiplied by the per cent of protein obtained by chemical methods equals the total expansion volume of the gluten in terms of c.c. per 100 g. of flour.

Tabulated and Plotted Results of Flour Analyses

A statistical study is then made every season (usually about August, when the new flour comes in) of the expansion factor with reference to the protein, gluten (by washing-out method) and the ash determinations. Table I gives the information in tabular form, supplemented by curves and comments thereon, of a typical season.

The curve sheets show clearly the variations encountered in flour analysis. Fig. 1 illustrates the variation met with in protein content and gluten value. Fig. 2 combines the data as given in Fig. 1 with the ash value, which is the index as to how the wheat was milled to produce the flour.

A high-grade flour most generally has a low ash value. A 40 per cent patent means that only 40 per cent of the wheat was used (i.e., the best part), while a 60 per cent patent would be milled from 60 per cent of the wheat and hence would contain more mineral matter, with a resulting higher ash content. It has been observed, however, that flour obtained from wheat grown on the

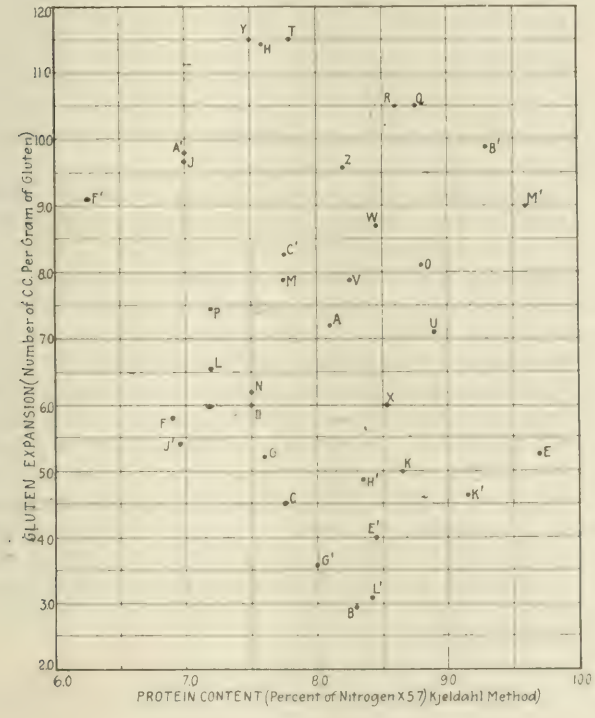

FIG. 1.

Pacific Coast has a high ash value due to the soil in which the wheat is grown.

The total gluten expansion value gives with one figure the combined quality and quantity value of the gluten. Having worked out, at the beginning of the season, charts similar to those given, it is a rather easy matter on subsequent analyses for the same season to determine just where a flour belongs and what it can best be used for, crackers or cakes, and also what kind of cakes.

The absorption value tells how much water to use in your mixes and the moisture determination tells how much water you are paying for.

In a similar manner, standard specifications were

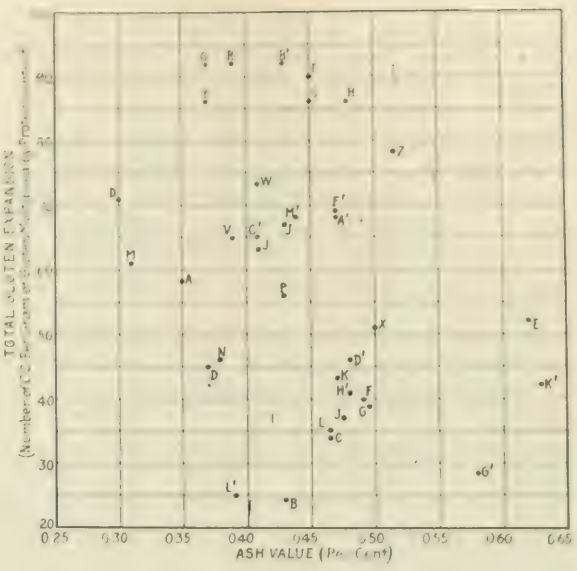

FIG. 2

worked out for other raw materials. Chief among these were:

1. Butter, lard and shorteners; in which it was found advisable to make melting point, refractometric, moisture, ash (including salt), casein determinations; obtaining fat by difference. Special attention must always be paid to color, taste and odor.

2. Milk products and milk powder; make ash, moisture, fat (Babcock method—Leach) determinations.

3. Molasses, syrups, sugar; make moisture, invert sugar and sucrose determinations.

4. Flavoring extracts; make specific gravity determinations and observe taste.

5. Baking powders; make acidity tests and determine starchy material.

TABLE I.

Lot Symbol	Protein in Per Cent (5.7 × N)	Gluten in Per Cent	Gluten Expansion in c.c.	Gluten Expansion per g. of Gluten (calc.)	Total Expansion per 100 g. of Flour (calc.)	Ash Value Per Cent

The most striking example of the methods of manufacture studies was "Ammonium Carbonate Versus Ammonium Bicarbonate." Merck's 1907 Index gives the following information about the two salts:

Ammonium Bicarbonate—Large, transparent crystals, soluble in water and alcohol. Decompose at 60 deg. C.

Ammonium Carbonate—Mixture of ammonium bicarbonate and ammonium carbamate. Crystals, white, effloresce in air, stringent ammonia odor, sharp saline taste, soluble in five parts water at 15 deg. C. Decomposed by hot water.

Analyzing the samples for ammonia content, it was found that the commercial products as furnished to the baking trade gave the following figures: Ammonium bicarbonate, 20.86 to 21.05 per cent. Ammonium carbonate varied from 22.50 to 25.60 per cent.

It will be readily seen that the ammonium carbonate does not aid in producing uniformity of product, as it is itself quite variable in constitution. It is true that as to ammonia content it is stronger and hence would be more economical, as its function is to produce volumes of ammonia gas. An attempt was made to get the same baking results by using ammonium bicarbonate in sufficient quantities to equal the ammonia content of ammonium carbonate. The results, however, did not equal those ordinarily obtained. It was then decided to investigate the manner of mixing and also the baking. This investigation showed that certain kinds of cakes must have a leavening agent which is capable of acting quickly upon the application of heat. This was found to be true of ammonium carbonate, as it is more unstable than ammonium bicarbonate.

Test of Acidity in Sponges Used in the Baking Industry

Another example of this type of studies is "Acidity in Sponges in the Making of Crackers."

By "sponge" in the baking of crackers is meant that portion of the raw materials which is mixed in advance with the fermenting agent. This sponge is allowed to stand for a long time, becoming acid due to the fermentation. This acidity is neutralized with sodium bicarbonate when the remainder of the raw materials are added to make the dough, which in turn goes through a fermenting period of short duration. Experience has shown that when all other figures or factors are constant, there has been developed an empirical relationship between the temperature of the sponge just before mixing and the amount of soda to be added. When other variables enter into the mixing conditions, erratic temperatures are obtained. To take these variables into consideration, the following chemical method was developed. The sponge is sampled and exactly 20 g. weighed out into a white enameled dish and distilled water added to dissolve the sponge thoroughly. Standard alkali is run in from a burette to neutralize the acidity, using phenolphthalein as an indicator. The burette is so graduated as to read per cents directly. A table furnished to the workman performing this test tells how much soda to add. This table was prepared in the laboratory making acidity determinations on the sponge and also on the finished products resulting therefrom. In this way any erratic temperatures are subjected to chemical checking.

The finished product and industrial engineering studies were more closely correlated than in the two preceding groups and accordingly do not offer isolated examples.

In the cracker industry we have the following factors entering into production and costs: In the making of approximately two hundred different kinds of finished products, sixty different materials are used. These products are made on ten different ovens or machines. Each product has its own die or cutter for cutting out the cake. Each dough has its ideal speed at which the cutter will work effectively. There is also an ideal time for baking and a certain number of operators are required for each product. The finished cakes will average so many to a pound, depending upon the cake. Similarly, there is an average weight for each packing container (large can, small can, wood boxes, barrels, drums and cartons), and there is a certain speed of packing, depending upon the size and nature of the product.

All of the above factors vary from day to day, and as a result the determination of standards representing ideal operating conditions was an extremely difficult task.

The standard method adopted by which to measure production and cost standards in the cracker baking industry requires a knowledge of the following:

1. Determine the number of cakes cut out with every stamp of the cutter.
2. Determine the ideal speed (ideal referring to speed at which the resultant product is best obtained) at which to operate the cutter, i.e., cuts per minute.
3. Determine the average number of cakes per lb.
4. Determine the minimum number of operators who can effectively turn out the product.

The above applies to manufacturing departments as contrasted to packing departments.

In the packing departments, it was necessary to set up an individual standard for each product in each and every kind of packing container.

Since the goods are sold on a pound basis, it is evident that the cost standard must include pounds in its expression or terms. Furthermore all production and cost standards involve time. If the machine cost variance is great and the machines are operated by the same number of operators, then the machine hour basis is most applicable. In the cracker-baking industry the variance is found in operators and not in the cost of the machines. Hence the most applicable and accurate production standard is expressed as pounds produced per operative hour or the pounds produced per person per hour. For cost work, it takes a more convenient form, its reciprocal, or part of an operative hour required to produce 100 lb.

In the course of a day there is manufactured approximately fifteen different styles of goods, each with a different rate of production as follows:

Product A	100 lb. per person per hour
Product B	174 lb. per person per hour
Product C	102 lb. per person per hour
Product D	170 lb. per person per hour
Product E	147 lb. per person per hour

The respective cost standards are:

Product A	1.000 operative hr. to produce 100 lb.
Product B	0.575 operative hr. to produce 100 lb.
Product C	0.980 operative hr. to produce 100 lb.
Product D	0.590 operative hr. to produce 100 lb.
Product E	0.680 operative hr. to produce 100 lb.

The production rate of "lb. per operative hr." is computed according to the following equation:

$$\textit{Pounds per operative hour} = \frac{\textit{Cakes per cut} \times \textit{cuts per min.} \times \textit{operating min. per hr.}}{\textit{Number of operators} \times \textit{cakes per lb.}}$$

It was necessary, in installing a system of this design, first to explain thoroughly to department heads just how the reports were to be made out—that is, to distinguish between direct help (working on the particular machine) and indirect help (foreman, mixers and others who are intermittently working on several varieties of goods at one time), to take accurate speeds and keep accurate time, so that the data represented true and actual conditions; secondly, to explain to the cost department assistants how to interpret correctly the data submitted and compute the production rates as well as to detect inconsistencies. For a certain period of time it was necessary to make computations of standards daily on each and every run in order to check up intentional carelessness on the part of some in assembling the data; after which it was possible to fix a certain standard rate of production. By dividing this standard rate of production for any given variety into the total pounds produced in any day, it is possible to obtain the time equivalent in operative hours of direct help of work produced. Dividing this time equivalent by the actual time spent by the operatives on the particular run, the efficiency of the run is obtained.

Standards Representative of Operating Conditions

If the efficiency thus obtained is abnormally low, then it is due to one of two conditions: (1) abnormal operating conditions (necessitating a change of standard), or else (2) indifference on the part of the operatives to maintain the production standard as set. In the case of abnormally high efficiencies, the standard is set too low, or else the data as submitted do not represent true conditions. In this way the standards receive constant checking and represent actual or operating conditions.

In the packing department it often occurs that several kinds of packages are being packed at one time off of one run, and therefore the best method to set standards was found to be by making time and motion studies for each and every piece and container. This requires careful and keen observation and unprejudiced conclusions. In a few instances it was found that group studies could be made.

Time and motion studies in the cracker industry on packing operations are quite different from studies in the machine shops, due to so many variables and also due the fact that the operators are girls unfamiliar with time and motion study work; hence it was most difficult to have them understand just what was wanted.

Factors in Time and Motion Studies

The following are the observations which must be made in connection with time and motion studies of packing operations in the cracker-baking industry:

1. How are crackers brought to the packers?
   (On conveyors or on trays in stacks.)
2. How are packing containers supplied to the packers?
3. Do packers pack from conveyors?
4. Movement of conveyors—intermittent or regular?
5. Kind of product—cracker or cake?
6. Size of product?
7. Shape of product?
8. Thickness of product?
9. Do products stick to conveying pans?
10. Are stackers required?
11. Time to pack each individual layer.
12. Time to face front of containers.
13. Number of crackers or cakes per row.
14. Number of rows per layer.
15. Number of layers per container.

Determination of Plant Efficiency

Having determined the standards, the efficiency is determined as follows: The weight of goods packed in style I container is divided by the standard (for that particular container), giving the time equivalent for style I; similarly style II is treated, etc. Then the time equivalents expressed in operative hours of work produced of all the styles of containers for one variety of product are added and the sum is divided by the total number of operative hours of direct help, giving the efficiency. It is more difficult to detect errors in setting standards in the packing operations, as the effect of any single standard is masked in arriving at the efficiency per cent.

The time equivalents or standard operative hours of work produced for all varieties in a department are totaled for a given period of time (usually a month). These totals are then divided into the departmental labor charge (includes both direct and indirect help for the same period of time), giving the operating labor cost per operative hour. Similarly, the same totals are divided into the departmental burden, giving the burden cost per operative hour.

In calculating the cost of labor and burden on any piece or variety of goods, the cost unit (part of an operative hour required to produce 100 lb.) is multiplied by the rate per operative hour, giving the cost per 100 lb.

Conclusion

The difficulties in installing a system of this kind are the usual ones met with in installing any new industrial engineering system, namely,

1. Convincing every one concerned as to the importance of co-operation.
2. Designing suitable forms, reports and cards.
3. Interpreting and straightening out details which cannot be covered by a set of general instructions.

It must be remembered that owing to seasonal variations in the raw materials, factory methods are constantly changing, and accordingly the members of the cost department must always be on the alert to detect any irregularities.

This system has been in operation for two years and has been developed to such an extent that standard costs as calculated are proved against the actual departmental costs with only a very small percentage of variance. In this way it is possible to ascertain just what goods are creating and what ones are not creating departmental profits and also to anticipate new production costs very accurately.

In connection with the time studies on packing operations, a piece rates schedule was set up which increased production without increasing costs. This schedule is closely co-ordinated and consistent with the cost standards as set.

Summarizing the results of this investigation it has been shown that some of the functions of the chemical engineer in the cracker and biscuit baking industry are:

(*a*) Setting up standard specifications for purchase and control, checking of raw materials used.

(*b*) Investigating methods of manufacture and giving technical assistance.

(*c*) Solving industrial engineering problems.

Cincinnati, Ohio.

Legal Notes

By Wellington Gustin

Judgment for Refusal to Ship Phosphate Upheld

The judgment of the Clinton Oil & Manufacturing Co. of Clinton, S. C., against J. H. Carpenter, president of the Tennessee Fertilizer Co. of Nashville, has been affirmed in the Supreme Court of South Carolina. The action was for damages for failure to deliver acid phosphate under a contract, the material part being in these words:

"J. H. Carpenter agrees that he will sell to the other parties to this contract . . . acid phosphate during the two seasons, May 1, 1916, to May 1, 1917, and May 1, 1917, to May 1, 1918, at the price of $8.50 per ton f.o.b. cars at the plant of Carolina Phosphate Co., near Greenville, the fertilizers to be paid for on May 1, 1917, and May 1, 1918, respectively."

The present case grows out of the transaction for the fiscal year May 1, 1916, to May 1, 1917, the amount of acid phosphate agreed to be sold being 1,000 tons. Of this amount 160 tons was delivered and defendant refused to deliver the balance of 840 tons.

The persons involved in the whole transaction are the Tennessee company, represented by Carpenter, its president; Sparrow, its secretary at Nashville; Todd, the local agent and manager of the Carolina Phosphate Co. at Greenville and an agency of the Tennessee company; Bryson, the head of two corporations organized under the laws of South Carolina, the Woodruff Oil & Fertilizer Co. at Woodruff, S. C., and the Clinton Oil & Manufacturing Co. at Clinton, S. C.

Holdings of the Court

Looking at the contract, the Supreme Court said the phosphate was to be delivered to the Clinton company before May 1, 1917, as it was the end of the fiscal year, and payment was then due. Therefore, if the plaintiff did not call for an execution of the contract by asking delivery to it before May 1 of the 1,000 tons, the plaintiff has been done no wrong.

The contract does not prescribe by what formality, in time or in agency, the buyer should call for delivery of the acid, said the court; it does not prescribe that the call for delivery shall be intermittent, or that it shall be in writing. The seller's witness testified that it was the custom of the trade in carrying out a contract of this kind to ship from time to time during the season, and not all at one time; the custom being to give orders from time to time with shipping instructions. There were six of such orders filled for plaintiff during the latter half of January, 1917, aggregating 160 tons, and all shipped to Woodruff.

Contention of Defendant

Now, the seller contended that he was instructed by buyer Feb. 1 not to make any further shipments until "we write you again," and that the buyer made no further call for shipment until April 30, when it telegraphed: "If compelled to have shipping instructions, ship balance Woodruff Clinton acid to Spartanburg." His consequent contention was that this instruction, though within the letter of the contract, came too late for him to comply with the contract, and it was therefore inoperative.

Further testimony showed that the Tennessee Fertilizer Co. wrote the buyer, plaintiff, on March 19, and inquired to ascertain "the total amount of acid phosphate which you will take during the current season, ending May 1, 1917," to which letter the buyer replied on March 21, that it "expected to take the amount the contract calls for." The court said that with this reply before him there was no warrant for defendant to have been misled by the buyer's letter of Feb. 1. Mr. Bryson testified that the seller frequently had been requested, in person and by phone message, to ship out the balance of the contract. But Todd testified he never recognized verbal orders coming to him over the phone, though he admitted he suspended shipments upon request by phone to do so.

The question of whether the buyer had ordered shipment of balance of goods in time for shipment before expiration of period the court held for the jury to decide, as was also the question of whether seller waived his right to have buyer's orders for shipment in time to ship goods before expiration of the period.

And it said that when one party to a contract notifies the other party that he elects to breach the contract, the other party need not make tender to sell, since tender would be an idle performance.

Again, the damages to a buyer for failure of the seller to deliver goods were measured by the market value of the goods at time and place of delivery, or, if not ascertainable at place of delivery, at nearest market place plus cost of shipment to place of delivery. But buyer's ability to have made a profit by resale to others may not be recovered as damages.

Held Guilty of Contempt for Refusal to Testify

William A. Rushworth has been held guilty of contempt in the Circuit Court for Cook County, Illinois, for failure to testify and to produce certain documents in the matter of the Imperial Trust Co. of Canada, Ltd., vs. W. Howard Jackson, the case now pending in the Supreme Court of Ontario, Canada. A commissioner has been appointed to take evidence of several witnesses in Chicago, including George M. Reynolds, president of the Continental & Commercial National Bank, Armour & Co., Stuart G. Shepard, Central Trust Co. of Illinois, Sheridan Trust Co., Colonel R. R. McCormick and a number of manufacturing companies. Responding to a subpœna, Rushworth appeared, but refused to testify or produce desired documents.

Counsel for Rushworth said he would refuse to obey the court's order on the ground that it was without jurisdiction and authority to enter such order, and that the Illinois statute permitting the taking of the evidence is contrary to Section 9, Article II of the Constitution of Illinois. An appeal from the court's order was allowed to the Supreme Court of Illinois.

The order of the court was for Rushworth to appear before the commissioner and answer questions as to:

"An agreement between William A. Rushworth and the Tennessee Copper Co., as regards the sale or purchase of toluol and sulphuric acid.

"A certain contract for the supply of toluol to the Canadian Explosives Co. by the Tennessee Copper Co.

"A certain copy of a tender for toluol to the Imperial Munitions Board for 15,000 gal. of toluol monthly on behalf of the Tennessee Copper Co. made through William A. Rushworth."

The Hot-Process Water Softener

A Study of the Rate of Sedimentation of Lime and Magnesia Precipitates During Softening at Low and High Temperatures—Plant Equipment: Reagent Proportioner, Tanks and Filter

By GEORGE H. GIBSON

THE hot-process softener, in its present form, is a recent development. By taking advantage of the fact that chemical reactions are more rapid and complete in hot water than in cold water, more efficient removal of scale- and sludge-forming substances are obtained. The apparatus performs the functions of the open feed-water heater usually found in steam-boiler plants, in addition to those of a softener, and less space, lighter foundations, less housing, less piping and fewer fittings are required than for a cold-process softener plus an independent heater. There are several reasons why scale-forming matter is more completely removed from hot water than from cold water.

Effect of Heat Upon Reactions

Chemical reactions are enormously accelerated by heat. This is a well-known and generally recognized fact, and was used in the household for ages before it assumed the dignity of a law of chemistry. Everyone knows that dishes and clothes are washed more rapidly and thoroughly in hot water than in cold water. Paper pulp is causticized in hot water, etc. The exact law connecting temperature and rapidity of chemical reaction has never been determined accurately, some chemists stating that the speed of reaction doubles for each 10 deg. C. added to the temperature, and others that chemical reactions are speeded up approx-

imately as the twentieth power of the absolute temperature. Those formulas are not in agreement, but everyone concedes that there is a tremendous increase in speed of reaction with rise in temperature.

Some years ago experiments were made in the chemical laboratory of the Harrison Safety Boiler Works to determine the effect of temperature upon the reactions which take place between softening reagents and scale-forming matter in boiler-feed water. The results are shown graphically in Fig. 1.

It will be seen that the reduction in hardness, that is, in content of calcium and magnesium salts, is much greater at the end of 10 min. in water at 210 deg. F. than at the end of 5 hr. in water at 50 deg. F.; in fact, 24-hr. treatment in cold water does not bring the scale forming matter down as much as does 10-min. treatment in hot water. Subsequent heating to the boiling point of the sample which has stood at 50 deg. F. for 5 hr. reduces the magnesium hydrate to less than 1 grain per gal., but the same result is obtained in hot water in 10 min. In performing these experiments, only sufficient softening chemical was added to combine with the scale-forming substances. In practice a slight excess is used, which reduces the hardness to lower figures.

Factors of Rate of Sedimentation

The precipitates resulting from the transformation of scale-forming substances also settle more rapidly and completely from hot water than from cold water. Solid particles suspended in water settle to the bottom if their density is greater than that of the water or rise to the top if their density is less than that of the water. The force acting upon the particles is its weight less the weight of water displaced, and the force by which it is resisted depends upon the extent of its surface and the viscosity of the fluid in which the particle is suspended, multiplied by the velocity of fall. A maximum velocity is reached at which the retarding force is just equal to the accelerating force.

Viscosity is the resistance which a fluid offers to shearing. The coefficient of viscosity may be defined as equal to the tangential force required to slide a unit surface at unit velocity a unit distance from another surface with the fluid between.

Obviously, a large particle will settle more rapidly than a small particle because it contains a greater mass, and hence is acted upon by a greater force, in proportion to its surface. Considering a spherical particle whose density is greater than that of water, the maximum velocity with which it falls is given by Stokes' formula

$$V = \frac{2}{9} \frac{D - d}{N} gr^2,$$

in which V is the velocity, D the density of the particle, d the density of the water, g the acceleration of gravity, r the radius of the particle and N the coefficient of viscosity.

In a water softener the precipitated particles are of various sizes and possibly of different densities, but any given particle will fall through water at a rate depending upon the viscosity, and it is therefore of interest to note how the viscosity of water changes with temperature as shown in Table I, by Thorpe & Rodger.

TABLE I.

Temp., Deg. F.	Coefficient of Viscosity	Temp., Deg. F.	Coefficient of Viscosity
32	0.01778	140	0.00468
50	0.01303	158	0.00406
68	0.01002	186	0.00356
86	0.00798	194	0.00316
104	0.00654	212	0.00283
122	0.00548		

At the freezing point the viscosity of water is over six times as great as at the boiling point, while as between water at 68 deg. F. and water at 212 deg. F., the increase in velocity of fall will be about four times.

Now consider how this applies in a water softener. Suppose we have a large tank full of absolutely quiet water. A particle of any given size will descend four times as far in an hour in hot water as it will in cold water.

Next, suppose we have a continuous softener in which the water is constantly flowing through the sedimentation tank. The rate of flow can be four times as great in a hot-process water softener as in a cold-process softener without carrying particles of a given size to the pump supply pipe; or, to put it in still another way, with a given rate of flow through the settling chamber, much smaller particles can be separated out in the hot-process softener than in the cold-process softener. The further fact that the particles formed in a hot-process softener are larger than those formed in a cold-process softener renders the advantage of the hot process still greater, since the velocity of fall increases as the square of the radius of the particle.

It is therefore plain why the preliminary heating of the water, a feature which is peculiar to the hot-process softener, gives more complete chemical reactions and more thorough removal of the resulting precipitates.

Report on Hot-Process Test Run

The completeness with which scale-forming matter is removed from water treated in a hot-process softener may be shown by the analyses of water (Table II) before and after treatment in a commercial installation. In considering these results, it should be borne in mind that a grain is 1/7,000 of a pound, or 1/58,415 of the weight of a gallon of water. The small amount of solids remaining in the treated water from a hot-process softener does not form scale in the boiler, but gathers a sludge, which is easily blown out.

The chemical reagents must be fed to a softener accurately in proportion to the amount of water and to the impurities in the water, so that the treated water may not deposit scale on the one hand, or contain an excess of unused reagents on the other. For proportioning the reagents to the raw-water supply various mechanical arrangements have been devised.

Methods of Proportioning Softener and Water

In some softeners, the raw water flowing to the softener turns a waterwheel or operates a tilting bucket which in turn operates dippers by which the reagents are ladled out to be mixed with the raw water. Such appliances, widely used with cold-process softeners, are usually located above the reaction chamber of the softener, involving the lifting or hoisting of the reagents 15 or 20 ft. or more above the ground level.

In other softeners, a certain portion of the water, divided from the main supply by means of orifices or weirs, flows through chambers containing the reagents. In one such proportioner, the water, in flowing through the reagent tank, becomes saturated. This method is faulty, however, since solubility varies greatly with temperature.

In another form the water displaces the reagent from a tank, at the same time diluting that which remains in the tank. Elaborate means for adjusting the orifices progressively as the reagents become more and more dilute are therefore required.

None of these methods is well adapted for feeding chemicals to a hot-process softener, which should be designed for operation under a few pounds back pressure, since it is necessary to carry a few pounds back pressure upon the exhaust steam in order to insure a temperature of at least 205 deg. F. of the treated water at all times. With the methods just mentioned, it is necessary that the chemical feeding equipment be inclosed within the steam space or else that the chemical and raw water, after being proportioned, be pumped into the softener against the back pressure. If the waterwheel, or the tilting bucket, is inclosed so that the reagents can flow by gravity directly to the reaction

TABLE II. ANALYSES OF WATER BEFORE AND AFTER SOFTENING

	Grains per U. S. Gallon Before Softening	After Softening
Calcium sulphate	13.00	None
Calcium carbonate	12.30	0.36
Magnesium carbonate	5.36	0.94

Organic and volatile	6.32	2.98
Sodium carbonate	.....	4.80
Sodium sulphate	0.64	12.60
Sodium chloride	2.28	1.92
Total non-incrusting solids	9.24	22.30
Free carbonic acid	2.45	.....

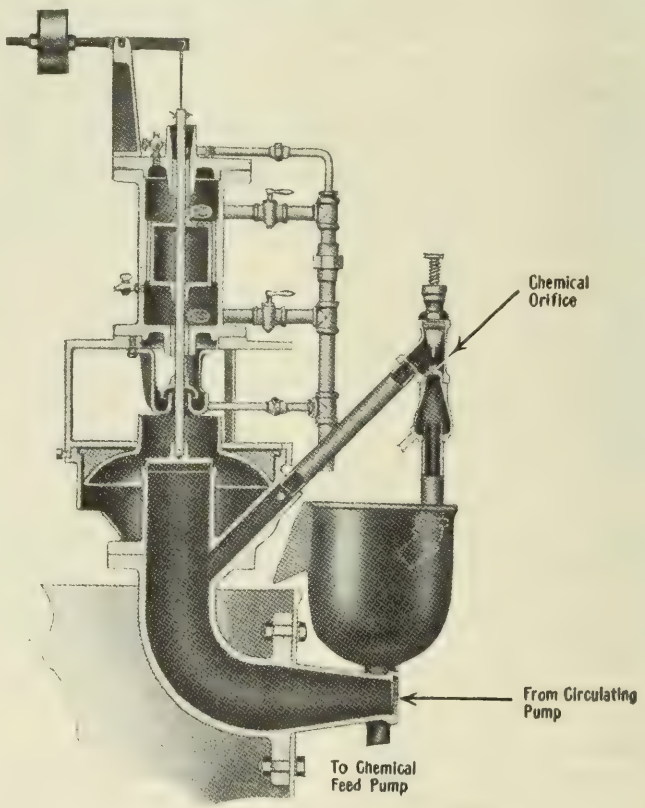

FIG. 2. CHEMICAL PROPORTIONER

chamber, steam finds its way into the chemical tank, where it condenses, diluting the reagents and rendering the feed inaccurate. The divided flow method involves an additional pumping of both the raw water and the reagent, and is therefore complicated and expensive.

In still another arrangement the raw water is passed through a hydraulic motor, of the reciprocating or of the rotary form, which drives a small chemical pump. This method is defective because it is practically impossible to prevent slippage past the valves and packings of such motors and pumps, which renders the proportioning inaccurate.

The chemical proportioner used in the Sorge Cochrane Hot-Process Softener to regulate the feed of chemicals in proportion to the flow of raw water is a true flow proportioner. The chemical to be fed to the softener is forced through an orifice by a pressure just equal to the differential pressure set up by the flow of the raw water through an orifice in the supply pipe.

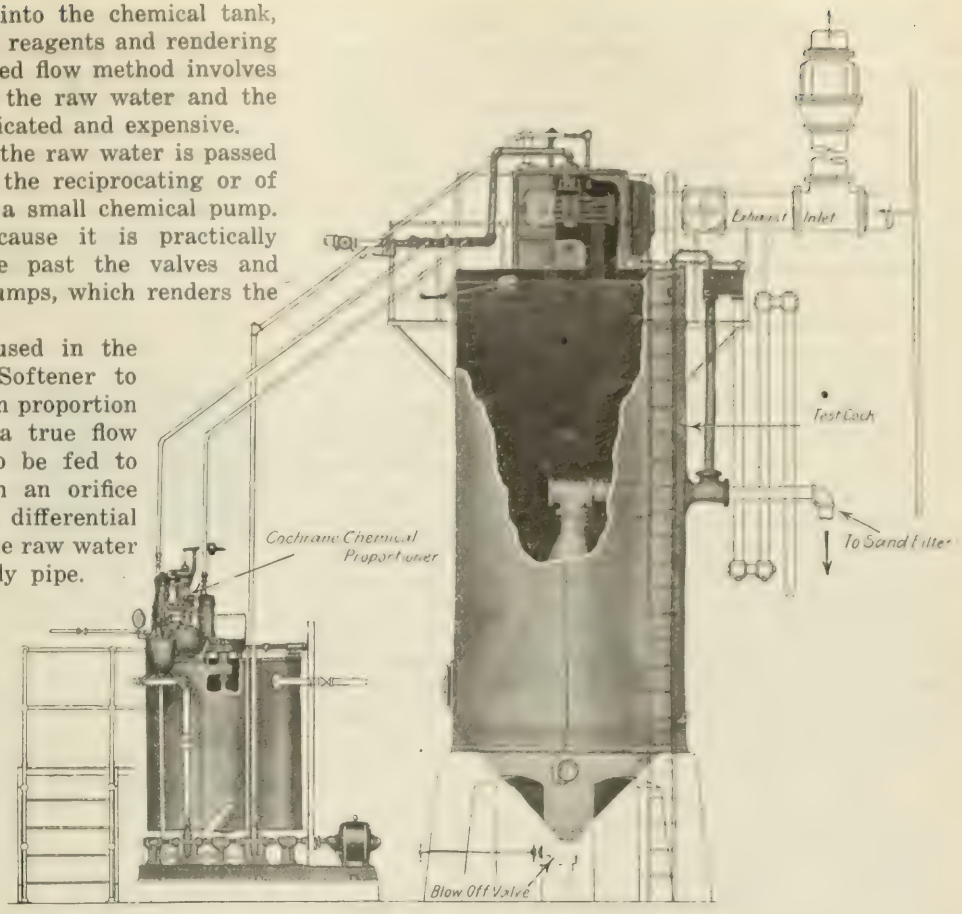

FIG. 3. HOT-PROCESS WATER SOFTENER INSTALLATION

Operation of the Softener

To understand how the device works, refer to Fig. 2. Between two flanges in the pipe through which the raw water flows to the heater at the top of the softener is placed a thin orifice disk. From the two sides of this orifice, small pipes lead to the opposite ends of a cylinder containing a piston. The piston is thus acted upon by the differential pressure due to the flow of water through the orifice. The vertical piston rod extends through water glands at each end of the cylinder. On the lower end of the rod is a valve disk, which closes over an opening through which a fluid mixture of the reagents is constantly being forced by a centrifugal circulating pump. The weight of the piston, rod and valve disk is counterbalanced. The differential pressure acting upon the piston pushes the disk down upon and tends to close the opening, while a pressure builds up underneath just sufficient to balance the differential pressure. The pressure of the chemical solution is therefore directly controlled by the differential pressure resulting from the flow of water through the orifice in the raw-water pipe. Through a simple pipe connection, this pressure acts directly at the chemical orifice, insuring an effective pressure on this orifice at all times equal to the differential pressure on the raw-water orifice. Most of the chemical solution supplied by the circulating pump flows out from under the disk and through a strainer and hence back into the chemical solution tank. The proportioned chemical flows through the chemical orifice into a funnel, from which it is taken by a chemical feed pump, lifted to the softener and forced in against any back pressure that may exist in the latter. The back pressure in the softener thus does not affect the proportioning. As the chemical, before escaping through the small orifice, is not in contact with air, no incrustation occurs therein, but to provide for dislodging any obstruction, a cleaning needle is so arranged that it can at any time be forced through the orifice by the pressure of the hand.

Besides being accurate, this arrangement has other advantages: Only one chemical solution tank is required, which is at the ground level, where it can be charged without hoisting of chemicals or inspected without climbing a ladder. The motor which drives the circulating pump also drives agitating paddles in the tank. Milk of lime can thus be kept in suspension and fed as well as purely fluid reagents. The large saturator tanks necessary where lime water is used are eliminated and the difficulty due to the fact that lime water varies in strength according to temperature is avoided. Solutions of caustic soda or sodium carbonate, lime water, milk of lime, or any mixtures, are all handled equally well and fed accurately.

The accuracy with which the solution is fed is well within 2 per cent, which is closer than attendants will measure out chemicals into the chemical tank. Representative test results are shown in the following table:

Rate of Flow of Raw Water Gal. per Hr.	Rate of Flow of Chemical Gal. per Hr.	Chemical per Gal. of Water	Variation Per Cent
1740	134.6	0.0773	0.28
1590	122.2	0.0769	0.22
1410	108.4	0.0769	0.22
1160	88.8	0.0766	0.71
710	54.6	0.0769	0.22
411	31.8	0.0773	0.28
290	22.4	0.0773	0.28
290	22.5	0.0775	0.52
184	14.3	0.0771	0.05

The chemical treatment is controlled by drawing a sample of the treated water from time to time and titrating with standardized solutions, the whole operation requiring about 10 min. By locating the titration readings thus obtained upon a chart for correct chemical treatment, the operator sees at a glance what change, if any, is required in the amount of the chemicals.

The apparatus, as may be seen in Fig. 3, is simple and compact. The open heater, with an oil separator attached for purifying the exhaust steam used for heating the water, is mounted directly over the reaction and sedimentation chamber. The water is heated to steam temperature by spraying it over trays, which also serves to release oxygen and other dissolved gases. It is then mixed with the reagent and fal's directly into the sedimentation tank. There is no constricted piping between heater and tank to become choked with scale. In fact, the water does not pass through piping from the time when it is first heated until it has been through the sedimentation chamber, even the overflow receiving only settled water.

The precipitated matter deposits in the conical bottom of the sedimentation chamber, from which it can be quickly washed by the opening of a single valve. In order to eliminate convection currents the hot water and the softening are delivered at the top and travel slowly to the bottom, from which the clarified water is drawn off by an inverted funnel. The precipitates formed when the water is first mixed with the chemical fall through the water below, securing a screening effect and gathering together the smaller particles. All precipitates are carried to the conical bottom of the tank, from which they are readily blown out by opening a sludge valve at the lower end or apex of the cone.

Filters

The removal of scale-forming matter at high temperature by sedimentation is so effective that for many waters and plant conditions it is entirely practicable to dispense with filters. Many softeners are accordingly installed without filters and are successfully protecting the boilers from scale and corrosion, even though the softened water contains a slight amount of suspended matter. Other conditions demand the use of filters, for which a low-pressure sand filter is placed between the sedimentation tank and the boiler-feed pumps or meter, the water flowing through the filter by gravity. These filters deliver a crystal-clear water which contains no solids except those in solution and no mud-forming properties except the amount which is below the exceedingly low limit of solubility of calcium and magnesium monocarbonates, silica, etc., at the boiling point. This water will leave no troublesome deposit in the feed lines, pumps or meters, and is particularly suitable for boilers operated at high ratings.

The filter is essentially a bed of fine sand resting upon a bed of gravel. Embedded in the gravel layer are strainer heads or valves. The strainer valves are of a self-cleaning type, having a movable head or disk which rests upon the stationary part of the valve in such a way as to leave small openings or ports around the edge. In back washing, the water is admitted through the strainers in a reverse direction and lifts the disks or heads, increasing the openings of the ports to double the normal size, with the result that any particles of sand or other substances which may have lodged in the port during the filtering operation are released and carried out by the wash water.

The strainers may be screwed into a collecting and wash-water distributing manifold, as illustrated in Fig. 4, or into a diaphragm.

Embedded in the gravel layer is an air-distribution system consisting of a main pipe with laterals, the latter perforated on the under side to permit the escape of air throughout the gravel layer. The air is used for loosening up the filter bed preliminary to back washing, the proper rate of air admission being controlled by an orifice in the pipe connection.

The filter chamber is connected to the softener through valves at the top or inlet and to the boiler-feed pump from the bottom or outlet chamber. There is also a valved bypass from the softener directly to the boiler-feed pump suction. The inlet and outlet of the filter are connected through hand-operated gate valves to a waste pipe, to which a relief valve at the inlet

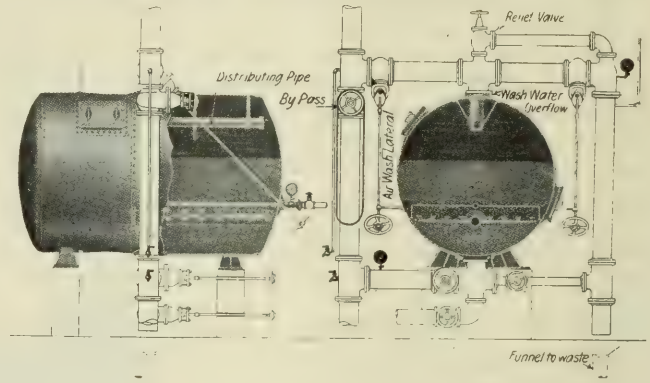

FIG. 4. HORIZONTAL SAND FILTER

also discharges. Finally, there is a connection to the outlet opening from a water supply, for back washing. A pressure gage is provided to show when the filter needs washing. Back washing is done at intervals, several times daily, the frequency depending upon the character of water. In some installations more than one filter is installed, so that it is not necessary to feed unfiltered water to the boilers while washing.

Canada's Special Overseas Trade Commission

The Canadian Trade Mission in England has been discontinued and in its stead there has been constituted the special trade commission to be known as the overseas branch associated with the trade commission office in the United Kingdom.

The duty of the overseas branch will be to make sales or purchases, or negotiate contracts for individuals or corporations. The aim will be:

1. To provide a convenient commercial meeting place for Canadians visiting London for business purposes, where they will be made welcome and can find men ready and willing to give them advice and information.

2. To have at hand full and permanent information as to conditions of trade, openings for business, demands for Canadian supplies, and possible contracts; to facilitate conferences with business firms, manage introductions to business houses and in every legitimate way aid Canadians to extend trade.

3. Conversely, the overseas branch will be a Canadian bureau of business information as to Canadian products where persons desirous of doing business with Canadians may find ready answers, careful directions, and sound, reliable counsel.

4. To give uniform and reasonable publicity to Canadian resources and productions and opportunities.

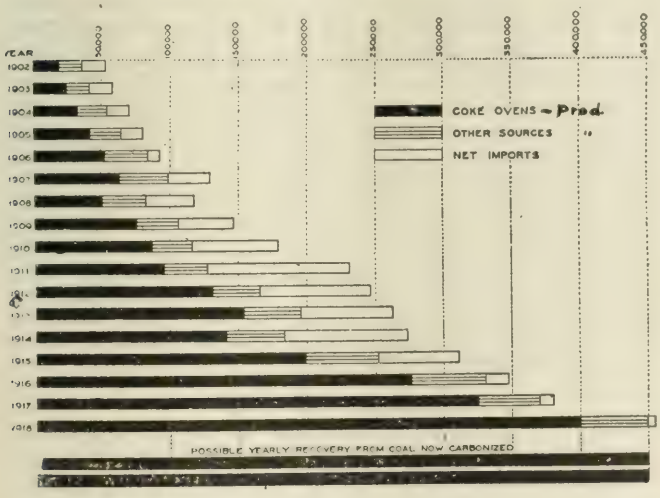
5. To establish a wideawake and efficient commercial liaison office between Canadian producers and world buyers in London, and to that end the overseas commercial branch in London will keep in close touch with the commercial intelligence branch of the Department of Trade and Commerce.

Synopsis of Recent Chemical & Metallurgical Literature

The Utilization of Coal Tar.—A comprehensive description of the operations of The Barrett Co., by PHILIP P. SHARPLES, will be found in *Gas Age*, March 10, 1920, p. 205. After outlining the scientific blending of various tars for roofing, road-building and road-preserving purposes, the author discusses the distillation of coal tar for the production of the raw materials used in the dye and other synthetic organic industries. When the maximum amounts of these materials are recovered by distillation, there remains in the retort a hard pitch. Of this, the author says:

"Before the war it was possible to export the excess of pitch for use abroad in making fuel briquets from the soft and friable European coals. Since the scarcity of shipping closed this outlet, stocks of pitch have accumulated to an incredible extent. Truly acres of pitch surround some of the plants, and The Barrett Co. has learned to its sorrow what the English tar distiller calls 'the burden of pitch.'

"A profitable tonnage use for hard varieties of pitch is still to be found, and until found, this handicap of



AMMONIUM SULPHATE PRODUCTION, CONSUMPTION AND IMPORTS

pitch will always overshadow the profitable production of coal-tar oils. Up to date our coals have been too good to require briquetting.

"Certain small uses have been developed for carefully prepared grades. Hard pitches are used in core compounds, in the manufacture of electrodes and in making clay pigeons. All the large uses of pitch, like roofing, paving and waterproofing, call for the softer grades with many of the oils left in."

At first, gas-house tar was the only tar available. Later, water-gas tar gave promise of becoming the dominant factor, but the adoption of the coke oven by the steel industry has given the lead to coke-oven tar. During 1918, about 263,000,000 gal. of coke-oven tar was produced, while the production of all other tars (including water-gas tar) was 161,000,000 gal. Gas-house tar production is nearly stationary, while coke-oven tar production is growing by leaps and bounds with the substitution of byproduct for beehive ovens. Whether this flood of tar can all be distilled and absorbed in the growing market for coal-tar materials, or whether its value as fuel will divert some of it to that field, is a problem of the future.

In the capacity of sales agents for many of the byproduct coke plants, The Barrett Co. is interested in the use of ammonium sulphate as a fertilizer. The accompanying chart shows the production, consumption and imports of ammonium sulphate from 1902 to 1918.

The double line at the bottom of the chart represents the amount of ammonium sulphate which would be produced at the present time from the amount of coal carbonized, were it not for the loss of ammonia caused by the use of beehive ovens.

Preparation of Methyl Chloride and Methyl Bromide From Dimethyl Sulphate.—In a note presented at the March 8 meeting of the French Academy of Sciences, CH. BOULIN and L. J. SIMON describe their work on the preparation of methyl chloride and methyl bromide (*Comptes Rendus*, vol. 170, No. 10, pp. 595-597). Methyl chloride is prepared preferably by the action of 16 deg. Bé. hydrochloric acid or less advantageously of sodium chloride on dimethyl sulphate according to the equations

$$SO_2(OCH_3)_2 + HCl = SO_2(OH)(OCH_3) + CH_3Cl$$

$$SO_2(OCH_3)_2 + NaCl + Aq = SO_2(ONa)(OCH_3) + CH_3Cl + Aq$$

When using hydrochloric acid the best operating temperature is 50 deg. C. The methyl chloride obtained contains only a few thousandths of methyl oxide, and the efficiency is 90 per cent. When using sodium chloride it is necessary to first bring the solution to 60 to 65 deg. C., at which temperature the reaction starts, and then cool down to 50 deg. C. The efficiency is about 90 per cent.

For the preparation of methyl bromide they use a concentrated solution of an alkaline bromide slightly acidulated with sulphuric acid and operate at a temperature of 30 to 35 deg. C. The efficiency is 90 per cent on the basis of the dimethyl sulphate used and practically quantitative on the basis of the bromine in the bromide used.

The Production of Tin in Australia.—In most tin-mining countries the bulk of the metal is obtained from alluvial workings, and although the tin from such deposits is by no means exhausted, such is the case with most of the easily worked deposits. Economic considerations prevent the utilization of the unworked deposits, and, on the whole, the day of alluvial tin mining is on the wane. Practically all the tin mined in Bolivia, and all mined in Cornwall, comes from lode mines, but this type of mining is unpopular in Australia. There are various reasons for this, such as a large proportion of failures of lode operations due to such causes as unfavorable location, bad management, unsuitable treatment plants and inadequate scale of operations. However, with the gradual elimination of alluvial deposits as producers and the increasing demand for tin, lode tin mining will probably receive greater attention in the future. This, according to J. B. LEWIS, who writes on the subject in *Chemical Engineering and Mining Review* (Australia), is satisfactory as far as Australia is concerned, for there are a large number of occur-

rences of tin in all the states, those in Tasmania being probably the richest and largest in extent, while in Victoria there are also extensive deposits.

There are difficulties to be overcome in dealing with these large deposits, for as a rule they are of low grade and to be profitable should be worked on a large scale, In the northeast of Tasmania are several lode tin fields, those at the Blue Tier and Aroca being the most extensive. Practically the only metal in the ore is tin, other minerals such as wolframite, molybdenite and ores of copper being found in very small quantities and in few places. At one mine over a period of about ten years the average recovery was 3.42 lb. of tin oxide per ton, which indicates that the original ore contained about 4¼ per cent of tin oxide. Near the west coast of Tasmania there is a belt of country where there are found large low-grade deposits of tin, copper, silver-lead and zinc ores, the Mt. Lyell copper mine and the Mt. Bischoff tin mine being well known.

It seems probable that an increasing amount of tin may be expected from Australia when the large low-grade deposits receive the attention they deserve.

Recent Chemical & Metallurgical Patents

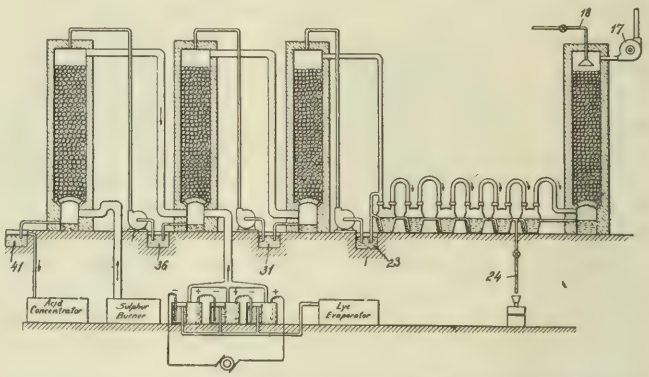
Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Use of Sodium Bisulphate in the Manufacture of Ammonium Sulphate.—When sodium bisulphate is used in place of sulphuric acid in the ammonia saturators, a double salt, $Na_2SO_4\ (NH_4)_2\ SO_4 4H_2O$, is formed. GERHARD N. VIS of Paris, France, describes a cyclic process of fractional crystallization for the separation of sodium and ammonium sulphates from the double salt. By heating the double salt and ammonium sulphate with water in the proper proportions, all of the ammonium sulphate goes into solution, while part of the sodium sulphate is dehydrated and remains undissolved. This is filtered off and the mother liquor cooled to 62 deg. C., when ammonium sulphate separates with a small amount of Na_2SO_4, which may be removed by washing with saturated $(NH_4)_2SO_4$ solution. The final mother liquor is treated with more double salt and $(NH_4)_2SO_4$ to restore the original composition of the solution and the cycle repeated. Attention is directed to the fact that 100 parts of H_2O saturated with $(NH_4)_2SO_4$ at 110 deg. C. dissolve 42.2 parts of Na_2SO_4 and the separation of the double salt from the solution only commences at about 60 deg. F. Further, the solubility of $(NH_4)_2SO_4$ in 100 parts of water saturated with Na_2SO_4 decreases nearly regularly from 102 to 75 parts when the temperature is reduced from 110 to 50 deg. C. (1,332,419; March 2, 1920.)

Simultaneous Production of Sulphuric and Hydrochloric Acids.—HENRI TOBLER of Hackensack, N. J., has adapted the following reaction to large scale production:

$$SO_2 + Cl_2 + 2H_2O = H_2SO_4 + 2HCl$$

As shown in the accompanying illustration, the apparatus consists essentially of three absorption towers similar in construction to Glover towers in series with a number of hydrochloric acid tourills and a fourth Glover tower. Sulphur dioxide is produced in a sulphur burner and delivered to the first tower, where a portion of the heat is utilized in concentrating and completing the removal of hydrochloric from the sulphuric acid formed later in the process. Passing to the second tower, the gas is mixed with chlorine from electrolytic cells. The reaction is completed in the third tower and the gases are drawn through the tourills and fourth tower by a suction fan, 17. A cold-water spray admitted at 18 serves to absorb the last portions of hydrochloric acid gas. Substantially pure hydrochloric acid is drawn



TOBLER APPARATUS FOR SIMULTANEOUS PRODUCTION OF SULPHURIC AND HYDROCHLORIC ACIDS

off through pipe 24, while the mixture of HCl and H_2SO_4 is pumped to the tops of the first three towers in succession. The mixed acid in sump 23 has a gravity of about 23 deg. Bé. After passing through the third tower, the liquid in sump 31 is about 36 deg. Bé. The proportion of H_2SO_4 increases steadily in the liquid, sump 36 containing 50 deg. Bé. acid and sump 41, 60 deg. Bé. H_2SO_4 containing practically no HCl. This acid is removed for further concentration to 66 deg. Bé. The products of this plant are HCl, H_2SO_4 and NaOH. The latter compound is obtained as a byproduct from the electrolytic cells which furnish chlorine for the process. (1,332,581; assigned to American Bromine Co., of Maywood, N. J.; March 2, 1920.)

Australian Patents

Complete specifications of Australian patents may be obtained from the Government Printer, Melbourne, one shilling each.

Preserving India Rubber.—To prevent the oxidation of rubber goods, the enzymes are destroyed by the application of a 10 per cent solution of ammonia containing about 0.3 per cent of a saponaceous substance such as sodium oleate, laurate and cresylic acid, carbolic acid or other antiseptic substance which will not precipitate the soapy material. The solution is applied to the latex, or to flexible rubber goods by immersion or by repeated superficial application. (Aust. Pat. 3,364; F. E. STOWE, New South Wales. Feb. 10, 1920.)

Extracting Copper.—To precipitate copper from a cuprous solution the latter is passed through a series of tanks arranged in terraced fashion and connected by launders. The tanks contain charcoal placed on perforated plates. The precipitated copper is separated from the charcoal by washing. The tanks may be divided into compartments by vertical partitions over and under which the solution passes from the inlet to the outlet launder. (Aust. Pat. 9,254; J. H. FLEMING, New Zealand. Dec. 23, 1919.)

Current Events
in the Chemical and Metallurgical Industries

Reorganization of Research in Applied Chemistry at M. I. T.

At a recent dinner tendered to nineteen members of the Research Laboratory of Applied Chemistry staff, Dr. William H. Walker made public his resignation as director of this laboratory. He was compelled to do this because of the pressure of duties in connection with his position as director of the Division of Industrial Co-operation and Research.

Coincident with the above announcement was the appointment of Prof. Robert E. Wilson, formerly assistant director, to the position of director. In view of the enlarged scope of laboratory work, two assistant directors were also appointed, Dr. C. S. Venable—in charge of organic problems, and Dr. L. W. Parsons—in charge of inorganic problems.

Prof. R. E. Wilson, who is taking the position left vacant by Dr. Walker's resignation, was graduated from the University of Wooster, Ohio, in 1914 and from Course X at the Institute in 1916. From that time until the present he has had broad experience in research work. During the spring and summer of 1915 he worked in the Research Laboratory of Physical Chemistry, and the following year was engaged in research for the General Electric Co. at Schenectady. He returned to the Institute as research associate in applied chemistry in the fall of 1916, but left in the spring of 1917 to act in the capacity of consulting chemical engineer in the Bureau of Mines. Under the direction of Prof. W. K. Lewis, he organized the first research laboratory for poison gas work.

When this work was expanded and moved from Pittsburgh to Washington, he was placed in charge of the smoke and absorbent units and was commissioned Captain and later Major in the Chemical Warfare Service. Upon completing his army work a year ago, he refused several important industrial research positions to take up his work at the Institute.

Dr. C. S. Venable was graduated from the University of North Carolina and received a Master's degree in 1911. He received his Ph.D. in organic chemistry from the Institute in 1917. As a Captain in the Chemical Warfare Service, he had responsible charge of much research and development work on toxic gases. He joined the Research Laboratory in April, 1919.

Dr. L. W. Parsons is a graduate of Course V, chemistry, in the class of 1913, and served as assistant in analytical chemistry for one year. From 1914 to 1916 he served as a teaching fellow at Harvard, and a year later received his Ph.D. from that institution. He served throughout most of the war as a Captain in the Chemical Warfare Service, aiding in the directing of research work on absorbents. He returned to the Institute as research associate in March, 1919.

The Research Laboratory was first organized in 1907 by Dr. Walker and under his direction has successfully solved a large number of industrial problems, as well as publishing twenty papers of general scientific interest. During the period of the war, the laboratory was closed, but was re-opened about a year ago. Starting then with seven members, the laboratory has grown rapidly until it now numbers fifteen full time workers, and several part time workers. The laboratory is now conducting a wide number of problems for such concerns as the Goodyear Tire & Rubber Co., Vacuum Oil Co., the National Electrolytic Co. and the National Tube Co.

Fixed Nitrogen Corporation Bill

With Senator Gronna's announcement on the floor of the Senate of views unmistakably in favor of the fixed nitrogen corporation bill, it is apparent that the measure soon will be reported favorably by the Senate Committee on Agriculture. Based largely on the assumption that Senator Gronna was not particularly friendly to the bill, some of those opposing the measure hoped that no prompt report on the bill would be forthcoming.

The determined way in which the Senate rejected the amendment to the fortifications appropriation bill, which would have curtailed expenditures at Muscle Shoals, is an indication of an overwhelming sentiment in favor of operating the plant and continuing the work.

Senator Underwood in an extended speech declared that "there are certain great interests in this country that have made up their minds to kill this plant." He declared that Senator Smoot, who was urging the amendment, had been misled on the proposition. Resentment was shown because the suggestion which resulted in the amendment came from Representative Graham. The Senate oftentimes does not take kindly to such suggestions from members of the House. In addition, in this case, many members of the Senate have no high opinions of the soundness of many of the conclusions which have been drawn by the Graham committee.

Dye Bill Before Senate

Consideration of the dyestuff bill began in the Senate May 1. Senator Frelinghuysen addressed the Senate at length, urging the passage of the bill, which he places second in importance to the Army and Navy bills, providing for the national defense. It is anticipated that extended debate will result before the measure can be passed.

Société de Chimie Industrielle

A meeting of the New York section of the Société de Chimie Industrielle will be held in Rumford Hall, 50 East 41st St., on Friday evening, May 14, beginning promptly at 8:30 o'clock. An informal dinner will be held at 6.30 P. M. Visitors are invited.

The program will be as follows:

"Commercial Relations Between France and the United States," the Hon. Maurice Casenave, chairman French High Commission to the United States; "Condition of Chemical Industry in the United States Before the War," Joseph H. Choate, general counsel of the Chemical Foundation, Inc.; election of officers, general business, social gathering and reception.

Aid for Austrian Engineers

There have been referred to Engineering Council by some of its member societies several appeals for aid to Austrian engineers. Consquently, at its meeting April 29, Council voted to instruct its secretary to prepare an appeal and transmit it to the member societies with request for publication.

A letter from the Austrian Society of Engineers in Private Practice is representative of the appeals for food:

> Fellow Craftsmen:—Austria is hungry! The supply of foodstuffs available is less than half enough. Hunger has lowered the standard of our work and has so undermined us physically that we can do nothing toward improving ourselves. We turn to America as the only state which can help us in our distress; the only nation in the world that can keep us from starving.
>
> There are 1,000 members of our organization in Austria in the various branches of engineers, such as electrical, mechanical, civil, mining, architectural and chemical. Approximately half of our members are wholly without employment, but even those who have work receive only on an average 1,500 kronen a month, a little more than $5.
>
> Through the American Relief Administration a means is provided for furnishing us with food. Americans can buy food drafts at any bank in America and send them to us by registered mail. On presentation of these drafts in Austria, the American Relief Administration Warehouse will deliver to us stipulated quantities and kinds of American food shipped to Austria for that purpose.
>
> You are our professional brothers—and we ask you to stand by us in our hour of need. We appeal to you, fellow craftsmen across the sea, to send us food drafts lest we starve!
>
> For further information apply to the American Relief Administration, 115 Broadway, New York, or to your own or the nearest bank.

There are also appeals for technical literature, such as books and back numbers of technical magazines issued since the middle of 1914.

Purple Dye From Shellfish

On the Pacific coast of Costa Rica, especially in the region about Cocos Bay, there abounds a kind of shellfish called the "nacascol," from which a fine purple color is obtained. So far no way has been found for preserving this dye, and the industry has remained in the hands of the few old people who take the trouble to dye a few ounces of thread every summer. The process is very simple. On picking up the shell from the beach or detaching it from a boulder, the gatherer blows her breath into it, whereupon a few drops of a greenish liquor ooze out. This liquor is collected in a clamshell, and after a sufficient quantity has been collected the thread is passed through it, soon after assuming, on exposure to the sunlight, a beautiful purple color, which is absolutely fast after it has turned purple. It is thought possible that the dye turns fast only on exposure to the air and that the liquor could be preserved by keeping the air away from it. There is little doubt that this industry of dyeing thread could be extended to much greater proportions if an extensive demand at good prices could be found for the dyestuff.

Fire in National Lead Co.'s Plant

On Sunday, May 2, fire broke out in the plant of the National Lead Co. on Staten Island. Some of the corroding stacks were burned and part of a small mill. The loss is estimated at between $50,000 and $75,000, fully covered by insurance.

Fellowships at the University of Utah

Seven teaching fellowships have been provided in the department of chemistry by the University of Utah for the academic year starting the fall of 1920. Dr. W. D. Bonner, in charge, has outlined an attractive series of investigations upon oil shales and other Utah raw materials.

American Cotton Seed and Cottonseed Products

Preliminary figures issued by the Bureau of Census show that 3,894,408 tons of cotton seed was received at the mills in the United States during the period from Aug. 1, 1919, to March 31, 1920, as compared with 4,051,797 tons during the corresponding period of 1919. These figures do not include 23,725 tons and 40,438 tons on hand Aug. 1, nor 151,650 tons and 113,869 tons reshipped or destroyed for 1920 and 1919, respectively. The amount of cotton seed crushed during the eight-month period was 3.704,978 tons in 1920, and 3.785,626 tons in 1919.

Imports of cottonseed products for the eight months ended March 31, 1920, amounted to 16,672,391 lb., and to 11,194,336 lb. during the corresponding period of the preceding year. Exports during this period consisted of 106,676,290 lb. of oil, 226,281 tons of cake and meal and 33,978 running bales of linters in 1920, as compared with 106,403,221 lb. of oil, 87,503 tons of cake and meal and 64,095 running bales of linters in 1919.

New Protection Against Deadly Gases

A new means of detecting the presence of carbon monoxide, which is the cause of many deaths in mines, has been perfected by Prof. C. R. Hoover. The device was invented by him in his chemical laboratory at Wesleyan University, Middletown, Conn. It is a delicate instrument which records not only the presence of the monoxide but also the quantity of it in the air. It consists of a small glass tube filled with a mixture of an iodine salt, pumice stone and fuming sulphuric acid. When impure air is admitted to the tube the contents turn green, the depth of the color indicating the percentage of CO.

The detector can be lowered by a string into shafts and then withdrawn for examination before anyone is permitted to enter. It is of special value in the iron and steel industries, in gas manufacture, for fire departments and in mine rescue work.

Mexican Directory of Domestic and Foreign Industries

The Mexican Confederation of Industrial Chambers has decided to publish a registry of foreign industries, having already in advanced preparation a registry of Mexican industries, and will furnish to foreign manufacturers and capitalists, without charge, information requested by them, unless, to obtain such information, it should be necessary to employ experts. It is requested that chambers of commerce, manufacturers' associations and similar organizations in the United States communicate directly with the Mexican organization, sending such data as will serve to co-operate in bringing the commercial and industrial interests of the two nations into mutually advantageous relations. The name of the Mexican body is Confederacion de Camaras Industriales de los Estados Mexicanos, Apartado 28, Mexico, D. F.

Carborundum Refractories to Be Made at Perth Amboy

The Carborundum Co., of Niagara Falls, N. Y., has acquired from the Alien Property Custodian the plant formerly owned and operated by the Didier-March Co. at Perth Amboy, N. J. The plant will be taken over at once and converted to the manufacture of a complete line of refractories.

The principal business of the Didier-March Co. was the manufacture of special refractory clay products, and practically all of its equipment will be utilized. The plant is located on a site of twenty-four acres fronting on the Raritan River and is well provided with wharfing facilities and railroad connections. It consists of a modern clay-working plant with a capacity of over one hundred tons per day and covers a floor space of about 300,000 sq.ft. The buildings are of substantial brick, steel and concrete construction, and there are also included office buildings, laboratories and ample housing facilities for employees. In addition to this property, the company acquires sixty acres of high-grade fire-clay lands at Bonhamton and a clay-excavating plant in operation.

The plant will be used exclusively for the manufacture of carborundum refractories. These are made in four regular grades, in addition to which special mixes are utilized in the production of saggers. These grades are known as Carbofrax "A," "B" and "C," and Refrax. All of the standard shapes in which fire-clay or silica brick are made can be produced in any of the grades, in addition to which practically any special shape, including tile, muffles and saggers, can be made in any of the three Carbofrax grades only.

Refractories made in any of the three Carbofrax grades are composed of over 90 per cent silicon carbide to which small percentages of highly refractory materials are added to facilitate binding. High refractibility is, therefore, maintained due to the fact that silicon carbide cannot be melted, and is decomposed into silicon vapor and graphite only above 4,000 deg. F.

In addition to the regular line of made-up refractories, the new plant at Perth Amboy will produce a complete line of high-grade refractory cements. It has not been found possible to produce a refractory cement which will cover all conditions, consequently ten special cements have been developed and these have been found to cover a great variety of requirements.

Large Canadian Chemical Company Organized

Chemical Products, Ltd., has secured the Trenton, Ont., plant of British Chemicals, Ltd., which was operated during the war for the production of acids and explosives. The new company is prepared to manufacture 75,000 tons of acid phosphate per year, and expects to engage in the production of acids, both sulphuric and nitric.

The plant has been re-arranged into four units where the following operations will be undertaken in a very large way in charge of A. H. C. Heitman:

Plant 1. Production of sulphuric acid and acid phosphate; production of nitric acid for general purposes.

Plant 2. Refined nitrate of soda, magnesium sulphate.

Plant 3. Salicylates and derivatives.

Plant 4. Ammonia and coke-oven byproducts.

Tennessee Copper & Chemical Corporation's Deficit

The largest lead chamber sulphuric acid plant in the world is located at Copper Hill, Tenn., and is operated by the Tennessee Copper & Chemical Corporation. It was erected to abate the nuisance caused by the great quantities of SO_2 produced during the smelting of the low-grade sulphide ores. It has a capacity of about 350,000 tons of 60 deg. acid per year.[1]

A deficit was returned for the last fiscal year, due largely to the fact that the acid makers were working under a 10-yr. contract with the International Agricultural Corporation for the entire output. An agreement which was attractive at the outset is evidently not so profitable at present. Fortunately for the Tennessee corporation, but unfortunately for the Agricultural company this contract expires on Dec. 31, 1920. It is understood that the Tennessee Copper & Chemical Corporation has already made tentative future arrangements with several fertilizer companies in which higher prices for 50 per cent of its acid will be obtained. This will leave a quantity of acid which can either be sold in the open market or utilized by the corporation itself in the manufacture of acid phosphate, which field it has recently entered.

The Southern Agricultural Corporation, a new company owned and controlled by the Tennessee Copper & Chemical Corporation, has been formed for the manufacture of fertilizer, and a new 100,000-ton plant is being erected at Atlanta, Ga. A phosphate rock property near Bartow, Fla., has also been acquired recently.

St. Louis Coke & Chemical Co.

A new plant being constructed in St. Louis for the St. Louis Coke & Chemical Co. occupies about 220 acres and will be served by ten miles of trackage facilities. On the site is being erected a 500-ton blast furnace which will be used for the manufacture of pig iron. The metal will not be cast into pigs, but will be conveyed in molten form in ladle cars to the plant of the National Stamping & Enameling Co., which adjoins the property.

Iron ore will be brought in by car and barge from the Minnesota districts and approximately 2,000 tons of Illinois coal will be carbonized daily. There will be eighty of the Robert type of ovens for the manufacture of coke. These ovens are 13 in. wide, 14 ft. high and 42 ft. long. The various carbonization products will be divided as follows: 1,400 tons of coke, 20,000 gal. of tar, 10,000,000 cu.ft. of gas, 6,000 gal. of motor fuel and 6,000 lb. of ammonium sulphate. All the byproducts with the exception of the ammonium sulphate will be utilized by the company.

Du Pont Company to Manufacture Artificial Silk

The du Pont company and the Comptoir des Textiles Artificiels, of Paris, France, have entered into an agreement whereby a new company will be formed in America for the manufacture of artificial silk. Announcement is made that the du Pont Fibersilk Co., with a capitalization of $4,000,000, has been organized.

The Comptoir des Textiles Artificiels controls practically all of the largest artificial silk plants in Europe.

It is anticipated that the plant will be in full operation within a year.

[1] For description of this plant see CHEMICAL & METALLURGICAL ENGINEERING, vol. 13, p. 194, Sept. 25, 1915.

Annual Reports of Metallurgical Companies

New Cornelia Copper Co.

Market conditions were unsatisfactory throughout the year 1919 and the company was unable to market a large quantity of copper, notwithstanding a considerable curtailment of production. This adversely affected the income account and increased the amount of copper on hand. The operating costs, however, were satisfactory. At the plant at Ajo 29,640,211 lb. of electrolytic copper was produced and 6,368,952 lb. shipped as cement copper. Sales of copper during the year amounted to about 30,000,000 lb., of which but 23,000,000 lb. was delivered.

The leaching and the electrolytic plants have worked satisfactorily. The hard lead anodes after thirty months service show very little corrosion. The leaching system has also worked satisfactorily. An inspection of the lead linings of the leaching tanks and the pumps shows that there has been no appreciable wear or deterioration on these installations. A six-compartment settling tank which will have capacity to take care of the slimes of the neutral solution before going to the sulphur dioxide reduction towers and the reduced iron solution after passing the towers is being installed. This will permit of the use for leaching of a tank that has been used as a settling tank and prevent the plugging of the reduction towers with slimes.

A 500-ton flotation mill was completed and put in operation late in August and 14,024 tons of sulphide ore was treated in the mill. This ore ran 1.275 per cent sulphide copper and 0.038 per cent oxide copper. A tailing was produced carrying 0.203 per cent sulphide and 0.028 per cent oxide copper, which represents a total recovery of 83.61 per cent. The ratio of concentration was 14.767 to 1.

Calumet & Arizona Mining Co.

The report of the Calumet and Arizona Mining Co., for the year ended Dec. 31, 1919, shows a production of 50,000,000 and sales amounting to 47,000,000 lb. of copper and a net income of $524,416 after charging off $1,381,948 to ore depletion. The year opened with a heavy balance of unsold copper in the hands of producers, which necessitated a curtailment in production. The last quarter of the year showed improvement in the demand for copper, and record sales were made in December for 1920 delivery. The average daily wages paid at the mines increased from $5.37 to $5.52.

During 1919 the smelter at Douglas treated 701,450 dry tons of ore, compared with 850,894 dry tons in 1918; the production for 1919 was about 56 per cent capacity, the decrease being largely in the blast-furnace department. Reduction in the blast-furnace department was made on account of the lower operating cost of the reverberatories, the decreased amount of oxide ore received and the gradual changing of all ores to a more desirable reverberatory charge. The roaster plant operated at full capacity the entire year.

On account of the curtailment of operations of the New Cornelia Copper Co., which consumes the largest portion of the acid produced by the acid plant, this plant was operated at about two-thirds capacity, producing 48,600 tons of 60 deg. Bé. acid compared with 67,100 tons in 1918.

On account of the deterioration of the tile lining inside the stack of the roaster department, it was necessary to remove the top 120 ft. of steel and all of the tile lining and to replace the old steel with new and completely reline the stack with acid-proof high-silica brick. When this is completed the roaster department will be in good condition. During the shut-down of the acid plant the towers of the acid plant were cleaned, putting this plant in good operating condition.

Judge Mining & Smelting Co.

Labor conditions in the Park City district and the unsatisfactory conditions of the zinc market during 1919 adversely affected the operations of the Judge Mining & Smelting Co. During the first part of the year there was an acute shortage of labor, and as a consequence it was impossible to obtain proper efficiency from the men obtainable. Agitation fostered by the Industrial Workers of the World resulted in a complete stoppage of operations for two months. Since the first of the present year, however, conditions have improved, better prices have been obtained for zinc and the surplus zinc on hand has begun to move.

For 1919 the metal content of all ores sold was: Silver, 410,307 oz.; lead, 6,989,908 lb.; copper, 276,926 lb.; gold, 462 oz.; zinc, 262,760 lb.

The electrolytic zinc plant operated for the first four months of 1919, when operations ceased because of the labor strike. Advantage was taken of the shut-down to carry on experimental work for the purpose of increasing the recovery of metal and to develop a process for the recovery of byproducts. The experimental work has been completed and the necessary changes in the plant have been made. Operation of the zinc plant was resumed in January, 1920, and zinc is now being produced of 99.95 per cent purity.

American Smelting & Refining Co.

The reconstruction period of 1919 adversely affected the business of smelting and refining of metals in the following important respects: (1) The reduction of mine production and a proportionate curtailment of operations of the smelters and refineries, which increased the cost of operation per ton treated. This made necessary the reduction of forces and readjustment of methods. (2) The cessation of demand for metals locked up the company's liquid capital and increased greatly the metal carried in stock. (3) The company's policy of accepting long-time contracts, many of which were entered into in the early stages of or prior to the war, became burdensome due to the increased cost of labor, fuels and supplies and because of the decreased efficiency of labor and higher freight rates. Average wages per 8-hr. day increased from $3.96 to $4.34.

The situation made necessary drastic measures to decrease expenditures. These were taken early in the year, and the beneficial results are shown in the net earnings, which for the first six months of 1919 were $2,149,159.66 and for the last six months of 1919 were $3,446,424.91.

The rising price of silver turned attention particularly to Mexico, and efforts were made to develop maximum output. Production was interrupted by the Villa activity in the late spring. All smelters in Mexico were in operation at the close of the year.

In order to increase ore production a substantial interest was purchased in the Premier mine, in British Columbia, and other options have been taken on several properties in that country. Over 90 per cent of the

Sabines Coal Co. has been acquired during the year. This property is located about one hundred miles from the Mexican border, and development will enable the Mexican smelters to be supplied with a satisfactory quality of coke at a lower cost.

A comparison showing the receipts from sale of metals and the metal production for the years 1918 and 1919 is given below.

RECEIPTS

From Sales of Metals:	1919	1918
Gold	$44,777,926.70	$40,624,998.17
Silver	64,105,415.60	54,547,364.28
Lead	21,573,831.43	34,955,070.42
Copper	81,281,842.45	208,840,411.45
Zinc	2,797,444.95	4,544,170.26
Tin	8,537,899.83	14,635,931.77
Other metals	2,032,790.26	1,912,540.40
Total	$225,107,151.22	$360,060,486.75

METAL PRODUCTS

	1919	1918
Ounces of gold produced	2,191,041	1,994,015
Ounces of silver produced	78,200,298	72,572,506
Ounces of platinum and palladium produced	1,824	1,516
Tons lead produced	208,439	260,192
Pounds copper produced	705,676,000	868,540,000
Pounds spelter produced	33,375,301	41,238,000
Pounds nickel produced	662,637	626,085
Pounds tin produced	15,340,000	19,868,000
Pounds sulphuric acid produced	40,362,000	87,338,000
Pounds arsenic produced	9,359,541	7,837,063
Pounds copper sulphate produced	3,675,499	5,164,000
Pounds byproduct metal produced	884,438	1,870,662

The company paid $6,681,242.25 in dividends, a decrease of $921,421.50 from 1918, practically all of this being on the common stock.

Portland Gold Mining Co.

The effect of the diminished purchasing power of gold is reflected in the annual report of the Portland Gold Mining Co. Operations during 1919 resulted in profits from mining and milling of $224,000, which, together with revenue from other sources, brought the net income to $234,636. Depreciation of mine and mill equipment was charged off to the extent of $174,666 and mine depletion to $146,313, resulting in a net loss to surplus of $92,817. Dividends of $240,000 were paid in 1919, the surplus for Jan. 1, 1920, being $819,531, a decrease of $332,817 from Jan. 1, 1919. Adverse conditions brought about by the war are still in effect in the Cripple Creek district.

Before the war ore of a value of $2 a ton was treated with greater profit than $3 ore yields at the present time, notwithstanding the many economies instituted during the war period.

Mount Morgan Gold Mining Co., Ltd.

The Mount Morgan Gold Mining Co., Ltd., of Queensland, Australia, for the six months ended Nov. 30, 1919, smelted 90,475 tons of ore and concentrate, recovered 2,749 tons of copper and 41,191 oz. of gold, and showed a surplus over expenditures of £43,333. Production of the mines was reduced about 40,000 tons below normal due to an epidemic of influenza and to a stoppage of operation brought about by the seamen's strike. Experimental work on leaching Mount Morgan ore in a unit treating one ton of calcines per 24 hr. gave satisfactory indications as to the recovery of copper, but gold extractions have not been so completely and satisfactorily demonstrated. With a view of obtaining more complete data a 10-ton unit is now being installed. This unit will, in addition to leaching copper from the calcines, also treat the residues for gold by chlorination.

Scarcity of German Dyes

In January, a committee from the British Color Users' Association of Manchester was sent to Germany to investigate the dyestuff situation and to report upon the available stocks now held in that country. This committee, after carefully examining the situation in Germany and after holding a number of conferences with leading German color manufacturers, has issued its report, in which it first states that it found the stocks of dyestuffs available in Germany to be very small indeed. It ascertained that very little, if any, manufacturing of dyestuffs was being carried on, owing principally to the shortage of raw materials and fuel, although conditions were slightly better in the sector at present under British occupation, where manufacturers were succeeding in turning out small quantities of dyes. It found that in some parts of Germany numerous foreign buyers had been trying to purchase any surplus stocks that might be had after the necessary 50 per cent had been set aside for the purposes of the Reparation Commission, but with no great success.

This British commission decided on a policy of buying on commercial lines on behalf of the whole body of color users, and bought for immediate export to Great Britain 140 tons of German dyestuffs for the approximate sum of £191,720 ($933,000 at normal exchange for the pound sterling) for the lot. Of course, the committee would have been better pleased if it could have secured a much larger quantity, but it found this to be impossible. The committee, however, entered into tentative negotiations with sundry manufacturers, and hopes, by reason of these, to receive larger and more varied shipments of dyes from Germany in the near future. Catalogues of all dyes already purchased are being prepared for the use of British consumers, and the committee has stated that, in its opinion, the best means whereby an adequate supply of dyes can be obtained will be by an organized plan for the purchase of all possible supplies wherever obtainable. Only by some concerted and well-organized effort can the British dye users expect to obtain in the future such stocks of European dyes as will enable them to meet all their requirements.

Finer Colors Lacking in British Dyes

There seems a definite fear among the color-using trades of the United Kingdom lest the British dye industry concentrate on the production of the commoner kinds of dyes to the neglect of the finer qualities and a wide range of varieties.

It is claimed that hundreds of dyes made in Germany are not being manufactured in Britain, and while all these are not essential dyes, they indicate that there is a far wider range of production in the German dye industry. British color users complain that the dye industry in Britain is a virtual monopoly, and is not paying sufficient attention to the requirements of the color-using trades, particularly in the matter of fine dyes.

It is fully admitted that many chemicals, never before manufactured, are being produced in Britain, but many more remain to be dealt with, as all the synthetic chemicals, whether dyes, drugs, etc., are associated in manufacture. This view receives some support from the recent Board of Trade order prohibiting export from the United Kingdom of all coal-tar products which form the basis of dyes and most chemicals.

Notice to Engineering Societies

On June 3 and 4, 1920, there will be a meeting at Washington of the Joint Conference Committee of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers to consider plans for organizing a national engineering organization.

The Joint Conference Committee has twice convened, the first meeting on Aug. 13, 14 and 15 and the second Sept. 15, 16 and 17 in 1919. The results of these meetings were published in a report, which was favorably acted upon by the governing boards of the several societies, and resolutions were adopted directing the committee to call a meeting of the engineering organizations of the United States for an organizing conference and to establish the proposed organization.

Any engineering society or organization not a branch of a national engineering society is eligible for membership in the organizing conference. Full information as to credentials may be had from the committee by addressing it at 29 West 39th St., New York.

India's 1919-20 Cotton Crop

The Indian Department of Statistics has issued its final memorandum on the acreage and yield of the 1919-20 cotton crop.

The total area reported is 23,063,000 acres—about 10 per cent more than the revised total for 1918-19. The estimated yield is 5,845,000 bales of 400 lb. each—47 per cent more than in the preceding year. Of the total yield Oomras represent 48 per cent, Bengal-Sind 23 per cent, Dholleras 9 per cent, Coompta-Dharwars and Broach 5 per cent each, Tinnevellys, Salems, and Cambodias 4 per cent, and Northerns and Westerns 3 per cent.

American Purchase of Bolivian Petroleum Deposits

A large tract of petroleum land held by Chilean capital is said to have been acquired by an American in Chile for £750,000. The center of the deposits is in the vicinity of Santa Cruz. It has been announced by the new petroleum interests that a petition will be submitted to the Bolivian Government for a concession to construct a railway line from Santa Cruz to Formosa, in northern Argentina, the construction to be facilitated by grants of government lands.

Must Label Wood Alcohol Products Poison

As a further means of protecting the general public against the dangers in the use of wood alcohol, the laws of the State of Massachusetts have been so amended that such articles as bay rum, toilet water, cosmetics, and drugs containing wood alcohol, must be labeled "Poison, for external use only." It is expected that this example will be followed by other states.

Freight Rates on Vegetable Oils

A proposition is before the Transcontinental Freight Bureau to restrict to the direct lines the application of rates on vegetable oils from the Pacific Coast to eastern destinations. At the present time these rates apply via practically all routes and transit privileges and are authorized in southwestern states, which will be greatly restricted if the proposition carries.

Book Reviews

MICROSCOPIC DETERMINATION OF ORE MINERALS. By *W. Myron Davy* and *C. Mason Farnham.* Thumb-indexed; cloth, 6 x 9; pp. 154, illus. New York: McGraw-Hill Book Co., 1920. Price, $2.50.

Although the compound microscope has been extensively utilized for opaque mineral classification since the appearance of William Campbell's epoch-marking paper in 1906, Joseph Murdoch's "Microscopical Determination of the Opaque Minerals," published in 1916, has been the only comprehensive manual or textbook available on the subject.

It is to be expected that a new branch of science will at first develop rather rapidly, that new ideas will be adopted, and that new methods will be originated. That this has been true of "Mineragraphy," the name adopted by Messrs. Davy and Farnham to designate the subject on which they have written, is unquestionable; and these authors have described in their "Microscopic Determination of Ore Minerals" the new technique and criteria that have been found most useful in several laboratories.

The book is not a rehash or an adaptation of Murdoch's work, but differs therefrom in many important particulars. For instance, the determinative tables in the new book are based primarily on micro-chemical tests instead of upon color, the basis of Murdoch's tables. Davy and Farnham use only six chemical reagents, while Murdoch used seventeen; and the new book gives some data on streaks and cleavages which are not mentioned in Murdoch's work. Davy and Farnham also give in detail simple methods for testing the electrical conductivity and the electro-potential of minerals in polished sections, and describe the use of electrolysis to etch and bring out the structure of such minerals. Finally, they have included a section on standard blowpipe and inorganic qualitative chemical tests.

Investigators familiar with Murdoch's book and who use the new work may miss a few features that they have found useful; but careful study of the new book indicates that its authors have simplified the subject, and have endeavored to eliminate the personal equation.

Although determinative tables and the necessary preliminary explanations fill most of the volume, one chapter is devoted to a very lucid explanation of the technique of polishing and examining specimens, while another treats of the photo-micrography of polished sections.

The most evident weakness of the book is the inadequacy and even incorrectness of the non-microscopic data offered. It is doubtless very difficult to decide where to draw the line, so the almost complete lack of crystallographic information may perhaps be condoned. It is not so easy, however, to overlook actual errors, such, for example, as the statements that the streak of pyrite is greenish to brownish-black (instead of just black), that of enargite is sometimes grayish (instead of black), and that of sphalerite is "pale (what?) to colorless." The experienced mineralogist will also be surprised to find the cleavage of alabandite described as *perfect* cubic, this being the same term applied, and properly so, to galena. He will further search in vain, for instance, for mention of the red streak often shown by tennantite, or the greenish streak on glazed paper or porcelain so characteristic of molybdenite. Finally, he may wonder why orpiment, realgar and many other translucent or transparent minerals of non-metallic luster are described, while vanadinite, pyromorphite, wulfenite, scheelite, monazite and other important ore minerals are omitted.

It is undeniable, however, that the defects or inconsistencies criticized detract little from the usefulness of the book as a guide to the *microscopic* classification of most ore minerals, and that, considered as a whole, the volume is admirably adapted to its purpose. It forms a welcome addition to the literature of "mineragraphy" or mineralography" (Murdoch), and should be owned and used by everyone interested in this fascinating and useful science.

G. M. Butler.

Personal

WILLIAM C. DOWD has resigned as chemist of the American Smelting & Refining Co., Pueblo, Col., to accept the position of chief chemist of the Austin plant of the American Radiator Co., Buffalo, N. Y.

Dr. H. N. HOLMES of Oberlin gave a series of three lectures before the California Section of the American Chemical Society. The first lecture, on "Emulsions," was given at the Chemistry Building, Stanford University, April 22; the second, on "Gels," on April 23 at the University of California. On the evening of April 24 Dr. Holmes lectured on "The Industrial Application of Colloid Chemistry" at the Chamber of Commerce rooms, San Francisco.

DAVID F. HOUSTON, Secretary of the Treasury, before the Chicago Chamber of Commerce, on April 23, discussed the nation's problems and the duty of Americans.

J. F. JOHNSON, formerly with the Procter & Gamble Co., Ivorydale, Ohio, is now chief chemist of the Lever Bros. Co., Cambridge, Mass.

THOMAS J. KEENAN, secretary of the T.A.P.P.I., has resigned as editor of *Paper* and is now located at Room 1102, 18 East 41st St., New York City.

ALEXANDER M. MACMILLAN, one of the head chemists in the Customs Inland Revenue Laboratory, Ottawa, Canada, has resigned, to enter a manufacturing concern.

Prof. E. G. MAHIN, of Purdue University, presented a paper on "Non-Metallic Inclusions in Steel" before the Indiana Section of the American Chemical Society on May 8.

Dr. VAN H. MANNING recently tendered his resignation as director of the Bureau of Mines, effective June 1, and is to become director of research with the recently organized American Petroleum Institute. Dr. F. G. COTTRELL succeeds him as director.

HARRY H. MERRICK was elected president of the Mississippi Valley Association in St. Louis, April 21.

Dr. F. S. MORTIMER, secretary of the Iowa Section of the American Chemical Society, has accepted a position on the staff of the National Aniline & Chemical Co., Buffalo, N. Y.

Prof. W. A. NOYES, of the University of Illinois, Urbana, Ill., addressed the meeting of the Chemical Society of Washington, D. C., on April 28. His subject was "Foundations of Chemical Development."

L. B. SHIPLEY, formerly chemist and technical representative in matters pertaining to coal-tar heavy oils for The Barrett Co., has accepted a similar position with Bernuth Lembcke Co., Inc., New York City.

LEON R. WHITCOMB has resigned as chemical engineer with Hill & Ferguson, New York City, to accept a position with the Refinite Co., Omaha, Neb.

Obituary

SAMUEL T. MORGAN, president of the Virginia-Carolina Chemical Co., who was well known in the fertilizer field, died at his home in Richmond, Va., on April 16.

I. FRANK STONE, formerly president of the National Aniline & Chemical Co. and one of the leading manufacturing chemists of the country, died in New York City, May 5, in his fifty-fourth year. Mr. Stone was born in Chicago and when only twenty-one years old founded there the firm of I. F. Stone, that later was changed to Stone & Ware and moved to New York City in 1897. Three years later he became head of the Schoelkopf, Hartford & Hanna Co., and in 1906 assumed the presidency of the National Aniline & Chemical Co. This last concern did much to further American chemistry after German products were cut off.

Current Market Reports

The Non-Ferrous Metal Market

New York, May 10, 1920.—The metal market has been in an unsatisfactory state for the last week, owing largely to difficulties of shipment. Tin dropped about five points. Silver continues to decline.

	Cents per Lb.
Copper, electrolytic	19.25
Aluminum, 98 to 99 per cent.	32@33
Antimony, wholesale lots	11.25
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	56.25
Lead, New York, spot	9.37½@9.50
Lead, E. St. Louis, spot	9.00 @9.12
Zinc, spot, New York	8.62½
Zinc, spot, E. St. Louis	8.25

OTHER METALS		
Silver	oz.	$1.05
Cadmium	lb.	1.40@1.50
Bismuth (500 lb. lots)	lb.	2.70
Cobalt	lb.	2.70@3.00
Magnesium (f.o.b. Niagara Falls)	lb.	1.60@1.85
Platinum	oz.	110@115
Iridium	oz.	300.00
Palladium	oz.	105@115
Mercury	75 lb.	85.00

FINISHED METAL PRODUCTS	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	23.00
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	32.00
Seamless high brass tubing	30.50

SCRAP METALS	Cents per Lb. Buying Price
Aluminum, cast scrap	21.75@22.75
Aluminum, sheet scrap	21.25@22.50
Copper, heavy machinery comp.	13.50@14.00
Copper, heavy and wire	13.50@13.75

No. 1 comp. turnings	10.25@10.75
Lead, tea	5.25@5.40
Lead, heavy	7.00@7.25
Zinc, scrap	4.25@4.50

The Iron and Steel Market

Pittsburgh, Pa., May 7, 1920.

There has been a further and very material increase in the railroad movement as affects the iron and steel industry, but the rail strike is by no means broken. The roads have made gains, through the return of a few more of the strikers, through receiving more help from volunteers and through means multiplying for getting around the difficulty, which is chiefly that of operating the yards. The Pittsburgh & Lake Erie is conspicuous by still being able to handle scarcely any freight, while even the passenger service on that line is very meager. The effect is felt particularly in the Youngstown district, but the two other lines in that territory, the Pennsylvania and the Baltimore & Ohio, are doing better, and the district is producing at least 50 per cent as much pig iron and steel as normally. As for the Pittsburgh district, it is doing probably 90 per cent or better.

An estimate can now be made that the production of pig iron in April in the country as a whole, some districts being affected by the rail strike and some not, was at about 17 per cent lower rate than production in March. Assuming capacity at 45,000,000 gross tons per annum, March production was at 90 per cent and April production at 75 per cent, but production had been increasing, and had it not been for the rail strike April would probably have shown a gain over March. Production of steel ingots probably

declined in much the same manner as production of pig iron. The pig iron production rate now is probably about 85 per cent of capacity.

Steel Shipments Heavier

There has been a slight decrease in the embargoes, permits are granted somewhat more freely, and there are somewhat better car supplies on the whole. Considerably more has been done in the past week than in the previous week by way of moving solid trainloads of finished steel, either direct to a large consumer or to classification yards, particularly in the West, that are free to operate and can distribute single cars to various consumers. The total movement of finished steel from mills has materially increased, and in a few cases the shipments have been exceeding the current production. In general, however, steel continues to pile up in mill warehouses and yards. It can readily be seen that the distribution of steel is inequitable, some consumers being entirely shut off, and it is quite probable that some consumers, with lines of communication open, are receiving more steel than they really need.

It seems to be a fair analysis that when the rail strike is ended, as presumably it will be some time, steel will be found to be more plentiful than it was before the strike started, through consumption having been more restricted than production, and this, of course, will have a bearing upon the market in general and upon prices in particular. The market is now extremely dull. Buyers are indisposed to make forward commitments, and as to prompt deliveries, they are more likely to get deliveries on orders already placed than on orders that might be placed at this time.

Prices Easier

There have been some declines in the premiums asked for very early deliveries, in from three to six weeks, bars being available at about 3.50c., as against 4c. a few weeks ago, and plates at 3.75c., against 4c. to 4.50c. For the farther forward deliveries, in from two to four months, there are no definite price declines, although some exceptional sales have been made at special prices, but there is some softening in the market.

It is now not an uncommon view in iron and steel trade circles that industry in general is marked for an early readjustment in activity and prices, and there are not a few who welcome the change. While the experience may be uncomfortable, good results are expected. Steel producers recognize that steel demand suffers from the fact that the cost of putting steel into employment is very high, both from the high prices ruling for other commodities used in conjunction with steel, and from wages being extremely high in proportion to the service rendered, and as steel prices, except for the fancy premium prices for very early deliveries, are quite moderate compared with many other commodities, the steel industry may gain more than it loses by there being a general industrial readjustment.

The Chemical and Allied Industrial Markets

New York, May 7, 1920.

The two questions uppermost in every market at the present time and for six weeks past are: (1) Are materials obtainable at any price? and (2) At what price? There is no need to enlarge upon the difficulties of shipment. Everybody in every industry is personally acquainted with the freight tie-up.

Acetic acid, 28 per cent, is to had at prices ranging from \$3.50@\$4.50 per cwt., depending upon quantity desired, as against \$2.75@\$3.50 of pre-strike listing, while 56 per cent is firmly fixed at \$6@\$7.50 per cwt. The sensational rise on *barium chloride* which started about two months back shows no signs of breaking and producers are unable to meet the situation by accepting contracts; small quantities of this material on the spot market are quoted at \$140@\$150 per ton. *Barium sulphate*, blanc fixe, dry, is in practically the same position, with 4½@6c. prevailing, against 3@5c. per lb. of the previous report, while blanc fixe, pulp, is practically off the market, current prices ranging from \$60@\$80, as compared with \$30@\$50 per ton of a few weeks ago. *Chlorine gas* can be had in 100-lb. liquid cylinders at 9@10½c. per lb., an advance of 2c. on the pound, which has been caused by curtailment of production and the scarcity of containers. Inquiries on *bleaching powder* and *soda ash* have fallen off considerably, which points to the conclusion that buyers, both foreign and domestic, realize that the present shortage has depleted the market of everything but small quantities and are unwilling to commit themselves on the prevailing premium prices. Producers have withdrawn quotations on *glauber's salt*, as the freight tie-up has very seriously affected this item. Nominal quotations ranging from \$1.50@\$2 per cwt. have been heard for small quantities of spot material. *Caustic potash* is again falling behind and it is reported that manufacturers are sold out for months ahead. Whatever material has been available during the week sold at 30@35c. per lb.

Coal-Tar Products

Inasmuch as many of the items are unobtainable and those that are available may be had only in small quantities, it will be sufficient to state a few of the prices which are not wholly nominal. Among these are *aniline oil*, which remains at former levels of 34@45c. per lb. and *aniline salts*, at 46@50c. per lb. One large producer who is the controlling factor in the *phthalic anhydride* market steadily maintains this item at 65@75c. per lb., while *toluol* is still listed at 28@30c. on contract, with considerable quantities of this material on hand.

Naval Stores

As noted last week, the prices listed in the naval stores market are those to become effective upon arrival of material in this market. This applies particularly to all grades of *rosin*, of which shipments are expected to arrive from the South soon. Savannah is being held up by a combination of labor troubles and the difficulties in coastwise shipping.

Vegetable Oils

Linseed oil has shown considerable weakness during the week. No activity has been manifested on the part of buyers, and as a result all grades have dropped. Current quotations are: *Linseed raw*, car lots, \$1.72; *raw*, tank cars, \$1.67; *boiled*, tank cars, \$1.75 per gal.

Ores and Semi-Finished Products

Fluorspar—We are advised that 700 tons of gravel fluorspar have been sold for \$25 per net ton, f.o.b. mines southern Illinois, with no analysis guaranty, contracts reading "Fairview Washed Gravel Fluorspar." Also, 1,250 tons were sold at the same price and same shipping point with an average guaranty of 85 per cent calcium fluoride and not over 6 per cent silica, while a small tonnage was sold at the same point, with no analysis guaranty, packed in barrels, at \$37.50 per ton. Producers in this territory are not desirous of accepting contracts for acid grades of fluorspar and have refused to make any quotations on these grades. During the past few weeks the demand has become more active, but a good many of the fluorspar companies are pretty well sold. It is asserted that they are holding a certain portion of their tonnage for an expected increase in price.

Vanadium Ore—Prices of vanadium ores are usually based on the vanadium content, and at present range from \$1 to \$3 per lb. of contained vanadium. The variation depends not only on the percentage of vanadium but also on the presence of lead, copper, arsenic, molybdenum, uranium, etc., which may be difficult of separation.

Ferro-Alloys

Ferromanganese is well sustained at former levels, \$200 being asked for last half delivery, and \$230@\$250 per ton for prompt. Continuous labor difficulties dating back to early December, 1919, combined with excessively heavy demand, are responsible for present rise, which occurred in rather consistent jumps of \$10 a week, from \$115 to the the present high mark at \$250.

Spiegeleisen came up \$10 during the week, from \$63@\$65 to the current price of \$73@\$75 per gross ton.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.		$0.65 $0 75
Acetone	lb.	$0.19 -$0 20	21 - .22

Sulphur, roll (brimstone)	100 lb.	3.20 - -	3 30 - 3.40
Tin bichloride (stannous)	lb.	42½- -	.46 - .50
Tin oxide	lb.	.60 - .63	.65 - -
Zinc carbonate, precipitate	lb.	.16 - 18	.19 - .20
Zinc chloride, gran.	lb.	.13 - -	.13½- .15
Zinc cyanide	lb.	.49 - -	.50 - .60
Zinc dust	lb.	.12¼- .12½	.13 - .15
Zinc oxide, U. S. P.	lb.	.18 - .19	.20 - .21
Zinc sulphate	lb.	.03½- .03¾	.04 - .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1 10 —	$1 25
Alpha naphthol, refined	lb.	1 40 —	1 60
Alpha naphthylamine	lb.	.50 —	.60
Aniline oil, drums extra	lb.	.34 —	.45
Aniline salts	lb.	.46 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.90 —	1 00
Benzaldehyde (f.f.c.)	lb.	2 00 —	2 10
Benzidine, base	lb.	1.35 —	1 40
Benzidine, sulphate	lb.	1 20 —	1 25
Benzoic acid, U.S.P.	lb.	.90 —	1 10
Benzoate of soda, U.S.P.	lb.	.80 —	1 00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.31
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate (nominal)	lb.	.50 —	.65
Beta naphthol, sublimed (nominal)	lb.	.70 —	.90
Beta naphthol, tech (nominal)	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2 25 —	2 40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 —	.19
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1 10 —	1 20
Cresylic acid, 95-97%, dark, in drums	gal.	1.00 —	1 05
Cresylic acid, 50%, first quality, drums	gal.	.65 —	.75
Dichlorbenzol	lb.	.08 —	.10
Diethylaniline	lb.	1.40 —	1 50
Dimethylaniline (nominal)	lb.	—	1 80
Dinitrobenzol	lb.	.30 —	.37
Dinitrochlorbenzol	lb.	.30 —	.35
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.40 —	.45
Dinitrotoluol	lb.	.40 —	.45
Dip oil, 25% tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine (nominal)	lb.	.55 —	.65
H-acid (non inad)	lb.	2 25 —	2 50
Metaphenylenediamine	lb.	1 15 —	1 80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1 70 —	1 85
Naphthaline, crushed, in bbls (250 lb.)	lb.	.15 —	-
Naphthaline, flake	lb.	.15 —	.17
Naphthaline, balls	lb.	.16 —	.18
Naphthionic acid, crude	lb.	.75 —	.85
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.40 —	.50
Nitrotoluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3 25 —	4 25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.85 —	1 25
Ortho-nitro-toluol	lb.	.35 —	.40
Ortho-toluidine	lb.	.35 —	.45
Para-amidophenol, base	lb.	2 50 —	3 50
Para-amidophenol, HCl	lb.	2 50 —	3 25
Para-dichlor-benzol	lb.	.08 —	.12
Paranitraniline	lb.	1 70 —	1 90
Para-nitro-toluol	lb.	1 15 —	1 [illegible]
Paraphenylenediamine	lb.	2 00 —	3 [illegible]
Paratoluidine	lb.	2 00 —	2 [illegible]
Phthalic anhydride	lb.	.65 —	.75
Phenol, U. S. P., in drums (about 240 lb.)	lb.	.12 —	.25
Pyridin	gal.	2 [illegible] —	2 [illegible]
Resorcin, crystal	lb.	4 75 —	4 [illegible]
Resorcin, pure	lb.	6 [illegible] —	6 [illegible]
Salicylic acid, tech., in bbls (110 lb.)	lb.	.50 —	.52
Salicylic acid, U. S. P.	lb.	.55 —	.61
Salol	lb.	.90 —	1 00

Solvent naphtha, water-white, in drums, 100 gal.	gal.	$0.25	—	$0.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.28	—	.32
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.....
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.44	—	.50
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	....
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	$0.36	—	$0.39
Beeswax, refined, light	lb.	.40	—	.41
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1. (nominal)	lb.	.80	—	.88
Carnauba, No. 2, regular (nominal)	lb.	.60	—	.70
Carnauba, No. 3, North Country (nominal)	lb.	.45	—	.46
Japan	lb.	.21	—	.22
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.....	—	.09½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	—	.09¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	—	.11¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.....	—	.13½
Paraffine waxes, refined, 133-135 m.p.	lb.	.14	—	.15
Paraffine waxes, refined, 135-137 m.p.	lb.	.16	—	.16½
Stearic acid, single pressed	lb.	.26	—	.27
Stearic acid, double pressed	lb.	.32	—	.29
Stearic acid, triple pressed	lb.	.32	—	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.65
Pine oil, pure, dest. dist	gal.	....
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine taroil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.38
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

*Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$16.95	—	$18.75
Rosin E-I	280 lb.	18.75	—	19.00
Rosin K-N	280 lb.	19.00	—	21.00
Rosin W. G.-W. W.	280 lb.	20.50	—	21.50
Wood rosin, bbl.	280 lb.	15.50	—	18.50
Spirits of turpentine	gal.	.....	—	2.50
Wood turpentine, steam dist.	gal.	2.35	—	2.40
Wood turpentine, dest. dist.	gal.	.....	—	2.00
Pine tar pitch, bbl.	200 lb.	8.40	—	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	—	15.00
Retort tar, bbl.	500 lb.	15.00	—	15.50
Rosin oil, first run	gal.	.92	—	.95
Rosin oil, second run	gal.	.94	—	.97
Rosin oil, third run	gal.	1.00	—	1.05
Rosin oil, fourth run	gal.	1.10	—	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.40½	—	$0.42
Upriver coarse	lb.	.29	—	.32
Upriver caucho ball	lb.	.30½	—	.33
Plantation—First latex crepe	lb.	.44	—	.45
Ribbed smoked sheets	lb.	.44½	—	....
Brown crepe, thin, clean	lb.	.42	—	....
Amber crepe No. 1	lb.	.40½	—	.41½

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0 18½	—	$0.20
Castor oil, AA, in bbls.	lb.	.20	—	.23
China wood oil, in bbls.	lb.	.24	—	.24½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.18½	—	.19½
Cocoanut oil, Cochin grade, in bbls (nominal)	lb.	.20	—	.21
Corn oil, crude, in bbls.	lb.	.17½	—	.18
Cottonseed oil, crude (f.o.b. mill)	lb.	.15¼	—	.16
Cottonseed oil, summer yellow	lb.	.18½	—	.19
Cottonseed oil, winter yellow	lb.	.21	—	.23
Linseed oil, raw, car lots	gal.	1.72	—	.....
Linseed oil, raw, tank cars	gal.	1.67	—	....
Linseed oil, boiled, car lots	gal.	1.75	—	....
Olive oil, commercial	gal.	2.75	—	3.00
Palm, Lagos	lb.	.15½	—	.16½
Palm, bright red	lb.	.14½	—	.17½
Palm, Niger	lb.	.14	—	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22	—	.23
Peanut oil, refined, in bbls.	lb.	.23	—	.26
Rapeseed oil, refined in bbls.	gal.	1.62	—	1.64
Rapeseed oil, blown, in bbls.	gal.	1.68	—	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.17	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.14	—	.14½

FISH

Winter pressed Menhaden	gal.	$1.17	—	$1.18
Yellow bleached Menhaden	gal.	1.20	—	1.22
White bleached Menhaden	gal.	1.23	—	1.24
Blown Menhaden	gal.	1.34	—	1.36

Noted April 7.

New York

BUFFALO—The Standard Oil Co., Elk and Babcock Sts., has awarded the contract for the construction of several additions to the Atlas Plant here, to John W. Cowper Co., Inc., Fidelity Bldg.

LONG ISLAND CITY—The Elcaya Co., Inc., 148 Madison Ave., New York City, is building a 4-story, 100x100-ft. factory and laboratory on 1st St. and Freeman Ave. Estimated cost, $75,000. J. Baker, 6 Jackson Ave., archt. and engr. Noted May 12.

LONG ISLAND CITY—The Nichols Copper Co. has filed plans for the construction of a 1-story building here. Estimated cost, $20,000.

North Carolina

LEXINGTON—The Bd. Comrs. plans to build a 2-story, 77x209-ft. high school here. A chemical laboratory will be installed in same. Estimated cost, $80,000. J. H. Cowles, supt.

ST. PAUL—The town will receive bids until May 20 for the construction of sewers, including a sewage disposal plant, etc. J. C. Lenthe, mayor.

Ohio

CINCINNATI—The Hercules Rubber Corp., 908 Union Central Bldg., plans to construct a 2- or 3-story, 200x200-ft. factory for the manufacture of auto tires. Estimated cost, $500,000. W. G. Brown, 2301 Union Central Bldg., engr.

CLEVELAND—The city received bid for the construction of a filtration plant at Baldwin, from R. E. Carey Co., West 112th

CLEVELAND—The Gilmore Chemical Co., 9498 St. Catherine Ave., has awarded the contract for the construction of a 1-story, 40x100-ft. factory addition, to the William Dunbar Co., 8261 Cedar Ave. Estimated cost, $25,000.

CLEVELAND—The Interstate Foundry Co., 3161 East 61st St., has awarded the contract for the construction of a 1-story, 80x160-ft. sand and core building, to the A. A. Lane Constr. Co., 1836 Euclid Ave. Estimated cost, $100,000.

LAKEWOOD (Cleveland P. O.)—The Bd. Educ. plans to build a junior high school on Jackson Ave. A chemical laboratory will be installed in same.

MASSILLON—The Massillon China Co., Inc., plans to construct a 1- and 2-story, 100x200-ft. pottery manufacturing plant, along the Baltimore & Ohio R.R. tracks north of West Main St. The plant will consist of 13 kilns, etc. Estimated cost, $200,000.

Pennsylvania

HOLMESBURG (Philadelphia P. O.)—The Robertson Lubricants Co., Bulletin Bldg., has awarded the contract for the construction of a 1-story, 26x60-ft. factory here, to Barclay, White & Co., 1713 Sansom St. The company will be in the market for chemicals which will be used for the manufacture of lubricants. Estimated cost, $10,000.

Texas

DALLAS—The Bd. Educ. will receive bids until May 29 for the construction of a 3-story high school on Haskell and McKinney Sts. A chemical laboratory will be installed in same. Estimated cost, $300,000. C. M. Moore, secy. W. B. Ittner, 911 Locust St., St. Louis, Mo., archt.

TEXARKANA — The Southern Steel Products Co., 520 Spring St., will build a refinery. Estimated cost, $60,000. Work will be done by day labor.

West Virginia

CLARKSBURG—The Phelps Can Co., Lawrence St., Baltimore, plans to build a 1- and 2-story plant on a 4½-acre site here, for the manufacture of cans, to include an 85-ft. main building and 6 adjoining buildings. Estimated cost, $100,000.

Wisconsin

MILWAUKEE—H. A. Poppert, 504 Cedar St., is in the market for brass foundry supplies.

SHEBOYGAN — The Amer. Hide & Leather Co., 1102 Wisconsin Ave., is having preliminary plans prepared for the construction of a 2-story, 50x130-ft. addition to its tannery on Wisconsin Ave. Estimated cost, $50,000. F. Schnellen, mgr. Juul & Smith, Imig Bldg., archts.

Cuba

CIENFUEGOS—The city will receive bids about June 1 for the construction of a mechanical filtration plant to have a 17,000,000-gal. capacity. Estimated cost, $150,000. A. Potter, 50 Church St., New York City, engr.

Ontario

GALT—The Galt Brass Co. will build two 1-story additions to its present plant here. Estimated cost, $50,000.

GUELPH—T. Eaton Co., Ltd., 190 Yonge St., Toronto, plans to build an office building and an addition to its store foundry and factory here. Estimated cost, $115,000. H. McGee, supt. W. A. Mahoney, 73 Quebec W., archt.

LONDON—C. H. Hyman & Co., Richmond St., is building a bark house in connection with its tannery on Richmond St. and will be in the market for leaching equipment. Estimated cost, $50,000. H. A. Meltride, Molsons Bank Bldg., archt.

OTTAWA—The city, c/o Sproule & Lee, archts., 2 College St., Toronto, will soon receive bids for the construction of a hospital to include an X-ray equipment. Estimated cost, $2,500,000.

TORONTO—The Hobbs Mfg. Co., 178 King St., W., has awarded the contract for converting a building into a plate glass factory, to William T. Sparling & Co., 126 Bay St. Estimated cost, $[illegible].

TORONTO—The United [illegible] Co., Ltd., 78 Broadview Ave., has awarded the contract for the construction of a one story factory addition on Broadview Ave., to E. E. Keating, 167 Yonge St. Estimated cost, $[illegible].

SARNIA—The Holmes Fdry. Co. has awarded the contract for the construction of a foundry building, to Wells & Gray, Confederation Life Bldg., Toronto. Estimated cost, $100,000.

SAULT STE. MARIE—The Algoma Steel Corp. has awarded the contract for furnishing finishing mills with hot beds and tables in connection with the $7,000,000 steel plant extension here, to the Morgan Eng. Co., Alliance, O.

Quebec

MESOPOTAMIA—The Shell Transport & Trading Co. plans to construct buildings and tanks and install equipment in connection with the proposed development of the oil fields here.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

THE AMERICAN CHEMICAL SOCIETY, N. Y. Section, will hold a regular meeting June 11, at the Chemists' Club.

THE AMERICAN DROP FORGE ASSOCIATION will hold its seventh annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 17, 18 and 19.

THE AMERICAN ELECTROPLATERS' SOCIETY will hold its eighth annual convention in Rochester, June 30 to July 3. Headquarters will be at the Seneca Hotel.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its semi-annual meeting in Montreal, June 21 and 22; Ottawa, June 23; Shawinigan, June 24 and 25, and La Tuque, June 26.

THE AMERICAN IRON AND STEEL INSTITUTE will hold its spring meeting May 28 at the Hotel Commodore, New York City.

THE AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

THE AMERICAN SOCIETY OF REFRIGERATING ENGINEERS will meet in St. Louis May 27 to 29.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its annual meeting at the New Monterey Hotel, Asbury Park, N. J., June 22 to 25.

THE AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18, inclusive.

THE CHEMICAL SOCIETY OF THE COLLEGE OF THE CITY OF NEW YORK announces the following lecture in the Doremus Lecture Theater: Friday, May 14, at 4 p.m., F. A. Epps, chief engineer, the Foamite Firefoam Co. (*Experimental, cinema and lantern.*)

THE INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA plans to hold its annual convention in the Auditorium Theater, Chicago, Ill., May 19, 20 and 21.

THE INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

THE IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

THE SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15. Chinese delegates have chartered the S. S. Ecuador for transportation to this conference.

THE NEW JERSEY CHEMICAL SOCIETY will hold a regular meeting and ladies' day Saturday afternoon and evening June 5, at Rutgers College, New Brunswick, N. J.

THE SOCIÉTÉ CHIMIE INDUSTRIELLE will hold a meeting at the Chemists' Club, May 14.

THE SOCIETY OF CHEMICAL INDUSTRY, American Section, will hold a meeting, May 21, at the Chemists' Club.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its twenty-seventh annual meeting June 29 to July 3, at the University of Michigan, Ann Arbor, Mich.

Industrial Notes

THE CARBORUNDUM CO. of Niagara Falls, N. Y., is to spend approximately half a million dollars in extending and improving its plant at Niagara Falls and its two big furnace plants, one at Niagara Falls, Ont., and the other at Shawinigan Falls, Que. The plan includes a 3-story addition to the paper and cloth plant at Niagara Falls in which are manufactured carborundum paper and cloth, carborundum garnet paper and cloth and aloxite cloth. This addition, which has just been finished, is 432 ft. long and 81 ft. wide and will provide greater facilities for the storing and curing of all paper and cloth products, and for the extension of the rubber-bonded wheel department. Another addition, just completed, will extend one of the wheel-making and kiln departments, the new building being two stories high, 96 ft. long and 64 ft. wide. Both of these new structures are of concrete and are of the most modern type. Other big extensions and improvements have been planned and work will be started immediately. These plans call for additions to the crushing departments and other improvements at the furnace plant at Niagara Falls., Ont., where the abrasive aloxite is made and at Shawinigan Falls, Que., where is located an extensive carborundum furnace plant.

THE LAKEWOOD ENGINEERING CO., Cleveland, Ohio, awarded the first prize of $1,000 for the best treatise on industrial haulage using Lakewood Tier-Lift trucks to Clarence Irving McNair, Jr., of Cloquet, Minn. Mr. McNair, who is secretary of the Northwest Paper Co. of Cloquet, won the prize with a paper entitled "Analysis of the Application of the Tier-Lift Truck to the Pulp and Paper Industry." The treatise indicates the possibilities of considerable savings in the handling of ground wood pulp by Tier-Lift to and from storage either with or without a steam house process. The arrangement suggested by Mr. McNair would effect a reduction of wood pulp losses due to deterioration from the growth of fungi or to disintegration from over-long storage. Second prize was awarded to F. C. Peters, chief mechanical engineer, and G. R. Reese, assistant mechanical engineer, New Jersey Zinc Co., Palmerton, Pa. This treatise, which deals with the handling of zinc oxide in barrels and bags, contains valuable data for the movement of bag or barrel packages. Theodore M. Prudden of the Whitin Machine Works, Whitinsville, Mass., was awarded third prize for an analysis entitled "The Tier-Lift Truck—Its Field of Usefulness." F. L. Usner, with L. V. Estes, Inc., of Chicago, received honorable mention. Mr. Usner's paper, "The Tier-Lift Method Applied to the Paper Industry," is an excellent supplement to Mr. McNair's treatise. It deals with the handling of baled rags and paper-making stock and contains valuable suggestions for the handling of finished rolls of paper. A splendid paper by Frederick L. Fish, industrial engineer with the Fisk Rubber Co., Chicopee Falls, Mass., was also given honorable mention. This treatise, "Application of Tier-Lift Truck to Stores Problem of Handling Materials," while it deals more specifically with the rubber industry, contains valuable suggestions for the general handling of stores. The award committee, consisting of A. Russell Bond of the *Scientific American Monthly*, Prof. Dexter S. Kimball, dean of the School of Engineering, Cornell University, and Irving A. Berndt, vice-president of C. E. Knoeppel, pronounced the standard of papers submitted unusually high and declared that the data received will add materially to present-day knowledge of factory haulage.

THE DRYING SYSTEM, INC., has recently moved its offices and factory to 11-17 South Desplaines St., Chicago, Ill. The increased floor space secured will allow an added production of varnish drying equipment.

THE ROHDE LABORATORY SUPPLY CO. has been incorporated under the laws of New York, and will be located at 17 Madison Ave., New York City, for the export and import of apparatus and instruments for all branches of science, chemicals and reagents.

THE INTERNATIONAL TIME RECORDING CO., of Endicott, N. Y., has established a distributing agency in Memphis, Tenn., with W. M. Richards in charge of the district.

THE WEATHERCROFT CO., of Cleveland, Ohio, has established branch offices in the Randolph Building, Memphis, Tenn. This branch will be in charge of F. H. Ford and will distribute roofing liquid and plastic cement.

THE CHINCA CHEMICAL CO., INC., has recently erected a plant at 344 Poplar Ave., Memphis, Tenn., for the manufacture of extracts, medicines and non-alcoholic beverages.

THE MOLINE-HOOPER CO. has been organized, with headquarters at Memphis, Tenn., to take over the Gale-Hooper Co., effective June 1, 1920. The officials of the new company are also officials of the Moline Plow Co. The new organization will engage in the manufacture of farm implements in general, as well as tractors and automobile trucks.

THE SQUARE D COMPANY, Detroit, Mich., announces that D. H. Colcord has been appointed advertising manager. Prior to this change he served in the capacity of director of research engineering, which position has been taken over by L. W. Strong, formerly of the publicity department of the Westinghouse Air Brake Co.

M. S. ORTH, president and director of Marden, Orth and Hastings Co., has severed his official connection with that company and will devote his time to other interests. Mr. Orth, who is one of the largest stockholders, retains his interests in the company.

THE COMBUSTION ENGINEERING CORPORATION, with offices at 11 Broadway, New York City, announces with regret the resignation of E. P. Moritz, its vice-president, in charge of sales. Mr. Moritz had been ill for some time previous to his resignation and owing to his continued ill health it has been necessary for him to retire from active business for some time. No successor to Mr. Moritz has been named by the company.

Manufacturers' Catalogs

THE CHARLESTON INDUSTRIAL CORP., which is operating the City of Nitro, W. Va., has issued a booklet entitled "Public Utilities, City of Nitro, W. Va." A technical description is given of the various public utilities which have been and are now in constant operation. Descriptions are also given of the boiler plant, power plant, steam and air distribution system and electrical system, fire alarm system, gas distribution system, water system, sewer system, railway system, together with maps and illustrations.

THE JEFFREY MANUFACTURING CO., Columbus, Ohio, announces a new publication, which is catalog No. 259, entitled "Jeffrey Shredders, Type E." Illustrations and descriptions are given of this Type E swing hammer shredder (ball-bearing) which is used for reducing wood chips, bark and other fibrous materials. Particular attention is called to the simplicity of design, provision made for capacity, for durability and accessibility of working parts, and its adaptability to the handling of a variety of materials under different conditions of installation and operation. Illustrations are also given of installations, together with plant layouts, engineering information and other data of service to plant manager and superintendent.

THE UNDER-FEED STOKER CO. OF AMERICA, Detroit, Mich., has just received from the press two catalogs, one on the "Design and Operation of Heating Furnaces," by Nelson G. Phelps, and the other "Industrial Heating Furnaces Equipped With Jones Under-Feed Mechanical Stokers." Many interesting photographs are given of actual installations, together with descriptive matter.

THE GRISCOM-RUSSELL CO., New York City, is distributing a small folder, Leaflet No. 6, which briefly describes all of the apparatus manufactured by this company and which is designed to be a ready reference. Bulletin No. 1,140 illustrates and describes the Stratton steam separator.

Latest Pronouncement On Damage by Smelter Smoke

FEDERAL Judge T. D. JOHNSON recently handed down an opinion and interlocutory decree which later will be summarized at length in these columns in connection with a brief historical review of the smoke litigation in the Salt Lake Valley, Utah. It may not be amiss, however, now to point out the important findings of the court.

An interesting swing of opinion regarding the real nature of smoke damage may be noted. Thus, the so-called Godfrey decree, which caused the abandonment of more than one smelting plant in that region and the installation of efficient dust-catching devices in the others, accepted the idea that certain plant and animal injury was due largely to compounds of sulphur and arsenic which condensed on particles of soot or other solid matter and settled with them to the ground. In this latest decree, however, the Judge stipulates that the smelters shall so operate that the chimney gases shall be as free as possible of all solid matter "except unconsumed carbon." Evidently this is a recognition of the experimental demonstration that plant injury is caused by breathing dilute SO_2 gas into stomata or breathing pores of the foliage, there to be converted into sulphuric acid by the nascent oxygen and moisture accompanying reduction of CO_2 in these little cells.

On the basis, implied if not expressed, that smoke damage in the vicinity of modernly equipped smelters is due solely to unduly high concentrations of SO_2, the Court finds:

First: That there is no so-called "invisible injury" to vegetation; that plants to be injured by SO_2 must be definitely marked or bleached; and that the sulphur content of plants is not an index of injury due to SO_2.

Second: That there is no injury to screening or wire fences because of the action of such gases as come from the smelters at Midvale and Murray.

Third: That there is no injury to animal life because of the operation of these plants.

Fourth: That there is no injury to health, except that resulting from nervous excitation and fearsome worries of supersensitive inhabitants. As a matter of fact, this mental condition seems to be prevalent among many so-called "smoke farmers." No solution of the smoke problem would be satisfactory to them short of absolute elimination of any smell of smoke. As a matter of fact, the Judge remarks that this condition would probably effectively bar smoke damage upon plants, due to the extreme dispersion then existing; and is a consummation to be hoped for.

It may fairly be said that the Court takes too narrow a view as to the law in this regard. If his idea should be carried to the extreme, that there shall be absolutely no nuisance to any one because of the operation of an industry, then no industry could survive. Even the street cars could not run nor could railways operate because, surely, these utilities annoy some people. The "balancing of inconveniences" has not been taken into account, and if the Court's view were to prevail, then logically a single irritable person might close an industry from which thousands of people gain livelihood.

Dr. P. J. O'GARA, of the American Smelting & Refining Co., may be pardoned if he sets another feather in his cap as a result of this decision, for it is unquestionably his enthusiastic and able smoke investigation which has indicated the safe method of operation for the Murray plant, to mention but one. Both his company and the United States Smelting Co., co-defendants in the present case, have maintained experiment stations, and of their work the Court says: "The research work of these scientific men has been admirable, and it is unfortunate that the plaintiffs and other farmers of the community have not taken more interest in the experimental farms of the defendants and profited by the information acquired in the operation of said farms and the experiments made at these stations."

Twenty years ago we recognized that fume particles would cause damage in territory surrounding smelters, and in the intervening time we have discovered how to eliminate all solids, given the necessary incentive, by dust chamber, baghouse and electrical precipitator. Little progress, however, has been made in abating the sulphur nuisance. One could on occasion build a smelter in a desert region, but straightway transportation and labor troubles cost more than smoke damage. Purchasing easements or title outright to nearby farms is a very expensive and not altogether sure alternative, as more than one manager can attest. Consequently the idea advanced long ago that SO_2 must be dispersed through high central chimneys and properly diluted by air before reaching the growing plants still remains valid, fortunately upheld by precise experimentation undertaken during the past few years.

In fact, this remains the only practicable solution of the smoke problem now known. Various projects for neutralization have been suggested, and the production of elemental sulphur from SO_2 has been thoroughly investigated, but it is unlikely that these methods can be utilized. Sulphuric acid and liquid sulphur dioxide are now manufactured at several smelters, but few of them are situated so that a considerable outside market can be served. An internal market for sulphur as a metallurgical reagent sounds like an attractive possibility, but on sober second thought it is seen to be only a palliative—smelters already have too much of it in their systems and eventually it must be eliminated in some way or other as a non-offensive or useful solid, liquid or gas. That is exactly the problem which always must be met!

Standardization That Will Work

ALMOST commendable step forward is being taken by the Association of Scientific Apparatus Manufacturers through the work of its Committee on Standardization of Apparatus. Apparatus catalogues filled with wonderful pictures and long lists of apparatus of every size and style and shape to suit any need or whim of the user are very impressive. But anyone who has undertaken to purchase from such a book has found it more of a disappointment than a real aid. It is most encouraging therefore to learn that the apparatus manufacturers are rapidly changing their practice so that they intend hereafter to list in their catalogues only the sizes and styles that they actually produce and regularly carry in stock or are on their shelves as purchases from other makers, domestic and foreign.

About one-half of the sizes of porcelain dishes or beakers will amply serve the need of any laboratory. In fact it is the practice of many to order either every alternate or every third size listed. Those who have ordered the even numbered sizes would be just as happy and just as well served with the odd numbers and vice versa. We, therefore, commend the tendency to eliminate some of these sizes that are merely listed, and actually to keep in stock ready for delivery everything that is described in the catalogue.

A standardization by all the manufacturers working together will have many other virtues besides making it possible to carry in stock all the listed equipment. It makes very little difference to the laboratory man whether a 400-c.c. flask is fitted by a number 5 or a number 7 rubber stopper, but he will appreciate it greatly if all makers will produce the same size flask with the same size neck so that when one is broken it may be replaced by another that may have been purchased from a different dealer without the necessity of using a different sized stopper in the apparatus. This interchangeability, though not vital, is of sufficient importance to justify considerable expenditure by the makers of glassware, whether blown or molded, to get together upon a common basis of size and style. Temporarily, the cost will be appreciable, but ultimately the gain to all parties concerned will far offset this temporary financial burden.

It is to be hoped that the Association of Apparatus Manufacturers and the American Chemical Society committees jointly will be able to make rapid progress to the ends which they have in mind. We would urge upon all purchasers of apparatus to extend to these committees their most cordial co-operation and support. Unnecessary difficulties need not be imposed because of individual whim or preference. You may be temporarily inconvenienced by having to change your practice as to size or style of apparatus, but ultimately you will greatly gain by the adoption of general specifications which all manufacturers and all users can strive together to maintain. When some of these ideals of standardization have been achieved, your purchasing problems will be greatly simplified; the bids you receive from different dealers will be comparable and will mean something to you; you can anticipate prompt deliveries of exactly what you order, and the cost of the product will ultimately be reduced because of the greater simplicity and lower expense of doing business upon a rational, practical basis.

Boiler Economy From Distilled Feed-Water

A CASUAL reader might wonder what place in the columns of CHEMICAL & METALLURGICAL ENGINEERING a subject would have so clearly understood to be in the field of mechanical engineering as steam generation and steam plant efficiency. Yet his doubts would be cleared if he remembered that a chemical engineer's problems are largely connected with the application of mechanical engineering to chemical and physical processes, such as the mixing and handling of materials of all sorts, their heating or refrigeration to various temperatures under various pressures, and the evaporation of large quantities of solutions, with or without the recovery of solvents. And by far the larger majority of his heating processes are conducted by means of steam. Yet chemical operations may commonly be observed proceeding with such an utter disregard of steam economy as to remind one of the ancient atmospheric engine which prompted JAMES WATT to invent the condenser.

Evaporating practice, it is true, has been perfected to the point where multiple effect operations are common, yet probably few chemical engineers have been prompted to suggest the same principles and much the same equipment for their boiler plant. Even at that they would only be utilizing a practice long standardized in steamship design.

All these reflections were suggested by hearing a recent address by PERCY H. THOMAS on the Chile Copper Co.'s large steam-electric plant at Tocopilla, Chile. Situated as it is on a desert coast, the amount of fresh water available was so limited that conditions actually were similar to those encountered by shipbuilders, and the same solution was arrived at, namely, running all prime movers in closed circuit with a condensing system, and making up by distilled water any deficiency due to leaks and imperfect condensation. At first blush, distilled water seems to be a rather expensive boiler feed, but actually it presents some important advantages both of convenience and cost.

At Tocopilla the main units are turbo-generators with the last stage under 28.5 to 29 in. vacuum. All the steam auxiliaries, however, work at normal pressure and exhaust into a single low-pressure evaporator shell, which in effect is quite similar to the surface condenser so familiar to power plant engineers. This condensed steam is then returned to the boilers as hot water, and its latent heat produces almost pound for pound the same amount of steam from the salt water surrounding the condenser tubes. Losses here are only those of radiation, which can be insulated to a minimum, and those due to a continuous wastage of a small amount of hot concentrated brine. Vapor from this hot brine is liquefied in turn by the condensate from the main exhaust, and even its latent heat is returned to the boilers. By such means a fresh supply of pure water is always available for a small additional amount of fuel, and the arrangement is such that no great complexity of unusual equipment must be looked after by the power-house employees.

The floating power plants in modern steamships have adopted the surface condenser more from lack of fresh water than from considerations of thermodynamic efficiency. Many land plants favor the jet condenser, usually because certain conditions of cooling water make it undesirable or too expensive to maintain surface condensers, and supply their boilers with a correspond-

ing stream of so-called fresh water, containing a variable amount of gases and solids in suspension and solution. Yet it has been remarked that turbine blades on shipboard were seldom if ever subjected to the destructive erosion so common in stationary plants and ordinarily ascribed to water mist, but really due to minute particles of solid matter. These minor advantages in the engines are of smaller interest to the chemical engineer than the economy in boiler practice which they reflect. Boilers run on distilled water evidently will be comparatively free from incrustations, with a correspondingly efficient heat transfer from the furnace gases to the hot water. Scale-free boilers are safer to operate and last considerably longer, and are capable of quickly assuming a heavy overload with small danger to the equipment.

All these advantages are as real to the boiler house attached to a chemical plant and furnishing steam mostly for evaporative or other heating use as it is for another boiler house generating steam for the hugest engines. Yet the economies are so substantial that a recent power house erected at Buffalo has been equipped for distilled make-up water, even in the neighborhood of such a tremendous reservoir of such excellent water as Lake Erie.

Rise and Fall of The Bessemer Rail

THE statistics of rail production in the United States in 1919, recently presented by the American Iron and Steel Institute, show in even more striking fashion than previous presentations have done the practical elimination of the bessemer rail. Only 214,121 tons of bessemer rails were produced, against 1,893,250 tons of open-hearth, showing a proportion of about nine to one in favor of the open-hearth. Only seven years earlier, in 1912, the proportion had been two to one for open-hearth, while in 1910 the bessemer had predominated, and in 1907 the proportion had been thirteen to one in favor of bessemer.

The nine to one proportion for open-hearth in 1919 was not all the story, however, for the proportion of bessemer in the various weights was as follows:

	Gross Tons, Total	Per Cent Bessemer
100 lb. and over	478,892	2.22
85-99 lb.	965,571	3.11
50-84 lb.	495,577	25.58
Under 50 lb.	263,803	17.72
Total	2,263,843	9.71

The percentages given above are those computed by the Institute, and are of the total output, but 96,422 tons of the total output was in re-rolled rails, so that the proportion of bessemer rails to total of new rails was somewhat larger than indicated. It is clear that the bessemer rail has been eliminated almost entirely for really heavy duty, i.e., for 85-pound rails and heavier.

The supplanting of the bessemer rail appears all the more remarkable when it is recalled that for nearly a quarter of a century the chief use of bessemer steel was for making rails. Captain ROBERT W. HUNT gives the Kelly Pneumatic Process Co. the honor of producing the first bessemer steel made in the United States. It was blown in a 2½-ton vessel at Wyandotte, Michigan, in the fall of 1864, working under American patents which post-dated BESSEMER'S. ALEXANDER L. HOLLEY and his associates were the first to bring the then new process to a commercial success, commencing operation of a 2½-ton vessel at Troy, N. Y., on Feb. 16, 1865, under the Bessemer patents which he had secured some time previous.

The first reported production of bessemer rails was in 1867, 2,277 tons. Ten years later, in 1877, the bessemer rail production, 385,865 tons, exceeded the iron rail production, 296,911 tons. The production of bessemer steel ingots and castings in 1877 was 500,524 tons, so that nearly all the rolling of bessemer steel was into rails. In 1887 there was 2,936,033 tons of bessemer ingots and castings and 2,101,904 tons of bessemer rails, while in 1890 there was 3,688,871 tons of ingots and castings to 1,867,837 tons of rails, but 1890 was the last year in which bessemer rails surpassed all other rolled forms of bessemer steel. The wire nail, a bessemer proposition, came out in 1886 to the extent of an estimated 600,000 kegs, the next year having an estimated production of 1,250,000 kegs. In 1886 it was shown, at the Riverside works at Wheeling, that welded pipe could be made of good quality with bessemer steel. Thus for two decades anyhow bessemer steel reigned supreme as the material one should use if he wanted to make rails. When the full production statistics for 1919 become available a close estimate can be made, but meanwhile the guess may be hazarded that in 1919, while 214,121 tons of bessemer steel rails was produced, about 5,000,000 tons of other finished steel products, bars, pipe, wire, sheets, tin plate, etc., was made of bessemer steel. Even though Mr. HOLLEY was regarded as the foremost apostle of the bessemer process, he once enthusiastically exclaimed: "I expect to live to see the American open-hearth process attend the funeral of the bessemer process!" He died too young, but apparently modern requirements are for better rail steel than can be made in a converter alone.

Only fifty tons of electric steel rails was made in 1919. In 1912 3,455 tons was made and in 1913, 2,436 tons, the two years making a high spot in the statistics for the electric rail. Final results of the experiment are presumably being awaited, but apart from that, it may readily be imagined that there has been neither energy nor money for experiments in the laying of additional electric rails. The matter may be taken up again under more favorable conditions.

Rail exports made a record in 1919 both in quantity, 652,449 tons, and in proportion of total output, approximately 30 per cent. The quantity left for domestic consumption was only 1,551,394 tons, which compares with the record made in 1906, 3,654,794 tons, as in that year there had been 3,977,887 tons production, 4,943 tons imports and 328,036 tons exports. It should not be assumed, however, as has so often been loosely stated, that the railroads were allowed to run down during the period of Government control. Renewals in 1919 were about 1,350,000 tons and in 1918 1,111,638 tons, this comparing with an average of 1,328,316 tons a year in the three years ended June 30, 1917, the period that had been selected as the "test period" in determining the amount of rental the Government should pay the railroad companies. Rail consumption last year was light chiefly because there was practically no new building either of road or of secondary track, and because there was no inordinate wear of rails, as there had been in the first few years of the present century through the introduction of much heavier rolling stock than the light sections then in track were able to carry efficiently.

A Study of the Lime-Soda Ash Water Softening Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest the criticism by W. M. Taylor[1] of the analytical study of Herrle and Gleeson[2], on the lime-soda ash water softening process and find several points with which to take exception. Mr. Taylor's discussion of minimum hardness applies when an insufficient amount of soda ash is used as he recommends, but when a slight excess of it is used, as recommended by the authors, the solubility of the calcium and magnesium carbonates is decreased enormously in accordance with the solubility product law.

As to whether an insufficient or slight excess of soda ash is in accordance with best engineering practice depends absolutely on the way the boilers are run. Large amounts of salts must not be allowed to accumulate in the system, as they cause the vaporization to be irregular, due to variations in concentration set up by localized vaporization and mixing lag, with the result that the very dangerous phenomenon known as priming is effected. The plant engineer who adopts Mr. Taylor's recommendations will have to keep his boilers well blown to prevent scale, or if he prefers to follow the ideas of Messrs. Herrle and Gleeson, he will have to tap off sufficient boiler water to get rid of his salts and prevent priming conditions. Good practice of either method will get results which can be measured in the coal pile.

It is to be regretted that Mr. Taylor criticized Messrs. Herrle and Gleeson so strongly, and assumed that they were "analytical chemists without engineering experience." Furthermore he introduced extraneous matter when he talked about zeolites, which was wholly aside from the subject. CHEMICAL ENGINEER.

Chemical Industry in Sweden

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your journal, vol. 22, No. 10, page 464, in the article "Chemical Industry in Sweden" there is found the following point: "There are a number of works established for the production of chromium salts, but only one of them remains and its future is dependent upon protection, according to the report published in the *Journal* of the Society of Chemical Industry."

The original report was mistaken. Our factory for chrome alum in Hagge, formerly belonging to Sandsta Elektriska Smältverk, carries on its production by a new method, invented by me, and we have no intention to demand protection. Our company not only sells the chrome alum to Swedish tanners, but moreover exports to Norway, Denmark, Finland, Germany and Czechoslovakia.

I would be obliged if you would correct this point in your journal. G. H. HUITMAN.

Director of the A. G. Metalloxider.

Stockholm, Sweden.

Conserving Radium as a National Asset

To the Editor of Chemical & Metallurgical Engineering

SIR:—I noticed your interesting editorial of April 7 on "Conserving Radium as a National Asset." I thought you might be interested in a few aspects of the question with which you are doubtless acquainted, but which were not mentioned in your editorial on this subject. It has been estimated at the Harvard Medical School that about 1 g. of radium element would be required for each 1,000,000 of population to treat efficiently the occurrence of cancer. Of the 110 to 120 g. that would be required according to this estimate, perhaps not more than 20 g. is now in the hands of institutions where it is being efficiently used.

The question has been considered by some authorities whether legislation is not justifiable, prohibiting entirely the use of radium for luminous paints. The hardship that might be worked on this industry would not be so great as it might appear on first thought. Mesothorium as a byproduct from the thoria industry is eminently suited for use in luminous materials; has a half-life of about 6⅔ years, corresponding roughly to that of the luminous paints themselves. On the other hand, its very short life compared to that of radium does not render it nearly so suitable for therapeutic purposes. The prospects are that about 4 g. equivalents of mesothorium can be supplied as a byproduct from the thoria industry in the United States annually. This might or might not take care of the total needs of this industry, depending upon its growth, but would be about all that could be expected from this source unless monazite sand were worked primarily for mesothorium, letting thoria become the byproduct. It is doubtful if mesothorium could stand this expense, certainly not for therapeutic purposes.

The general hardship that might be worked by such legislation on radium producers in cutting them off from the market for luminous materials could be justly compensated by an offer of Congress to buy at a fair price all the radium that they could produce. This could then be disposed of by several different plans—either held for sale to hospitals or loaned to them, or, if Congress felt sufficiently generous, presented to them. The total appropriation required to produce radium up to the estimated needs of the country would be about $10,000,000 or $12,000,000—a very small expenditure considering the tremendous importance of the object. The material accumulated would be useful for hundreds of years; a delay in putting some such program into effect might preclude its ultimate possibility at any cost.

You have touched in your editorial on a very large question of public interest and one that I feel ought to be kept constantly in mind. It is improbable that anything effective can ever be done without an active insistence from the medical profession of this country. The signs that such a sentiment is growing within the profession are very encouraging, but its development may be so slow that it will come to a climax too late. That appears to me to be the great danger of the present situation. S. C. LIND.

Golden, Col.

Relationship Between Dendritic Structure and Ferrite Mesh

Fir-Tree Crystals Do Not Influence Directly the Location of Ferrite Shells Either in Ingot Structure or After Drastic Heat Treatments, While the Physical Properties of Normalized Castings Depend Primarily on an Improvement of the Pearlitic Kernels by Gradual Diffusion of Segregates

BY FEDERICO GIOLITTI

WHOEVER is occupied with "normalizing heat treatments"—those reheatings designed to obliterate ingot structure thoroughly and equalize completely any minor segregations of soluble elements—such a one has often had an opportunity to observe anomalous results which are difficult if not impossible to reconcile with the elementary facts plotted in the commonly used equilibrium diagrams. His technical problems are often much too varied and complex to fit into the relatively simple generalizations accepted at present in metallography, depending as they do on the phase changes at different temperatures in the state of solid solution or the state of aggregation of the respective components, modified in turn by the allotropic transformations in the iron. But in addition to this state of affairs, indicating the necessity of seeking data for the completion of metallographical theory, one can readily call to mind many unsolved problems evidently closely connected with theoretical metallurgy and yet closely related to heat-treatment practice.

I have published in collaboration with Dr. P. Forcella in *La Metallurgia Italiana* (vol. 6)[1] a discussion of one of the latter class of phenomena, namely, the relationship between dendritic structure and excess constituent, which was investigated incidentally to a very extensive series of thermal studies. These, it may be said, consisted of analyzing the autographic differential cooling curves of two samples of steel from the same piece, subjected simultaneously to known heat treatments. It may be said that in a great many cases the form of these differential curves (especially for certain types of steel) could not be harmonized with the commonly accepted ideas of diffusion serving as a basis for logical normalizing practice, and in general did not reflect as well as would be imagined the known history of the pieces studied.

A second group of phenomena belonging perhaps to theoretical metallurgy is comprised by facts about the morphological or crystalline character of the metallic phases at various temperatures and after various heat treatments. These will be touched upon in the course of this discussion, from a standpoint already developed by the author in "Crystallography of Alpha and Beta Iron," published in CHEMICAL & METALLURGICAL ENGINEERING, vol. 22, No. 13, p. 585 (March 31, 1920), at which place the relations were discussed which should apparently exist between the structure of the pro-eutectoid ferrite and the forms of the primary austenite crystals.

A material was selected analogous to that studied closely by Tschernoff, and which develops clearly defined dendrites in what is generally considered to be the characteristic shape of freely-growing solid solution crystals. This metal was an acid open-hearth nickel steel of the following composition:

C	0 42	S	0 008
Mn	0 60	P	0 02
Si	0 22	Ni	2 02

The steel itself was cast into 1-ton, square ingots,

[1] These studies were partially published in *La Metallurgia Italiana*, 1913, p. 804: "On the Control of the Preliminary Heat Treatment of Steel in Large Masses," by F. Giolitti and S. Zublena, and more fully analyzed in the present author's book, "Preliminary Heat Treatment of Soft and Medium Steels."

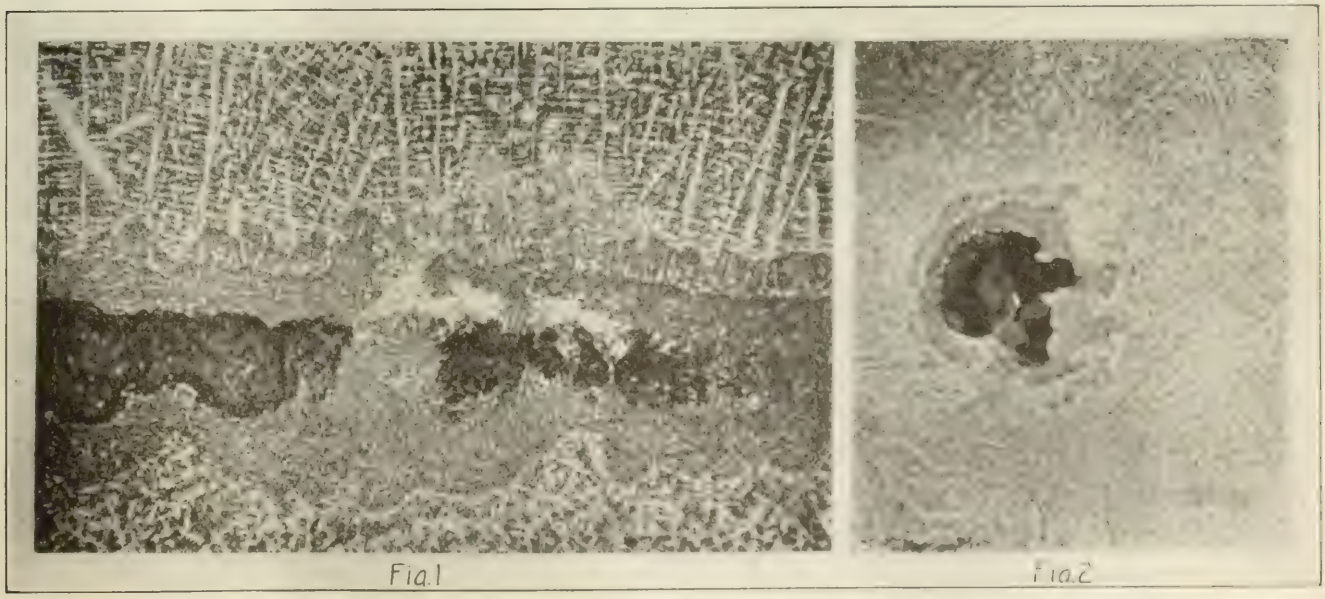

FIG. 1. Section cut along axis of ingot. Cavity extending from left to right represents the pipe, which, of course, was vertical in the original ingot. × 1. Etched 1 hr. with 20 per cent H_2SO_4 at 60 deg. C.

FIG. 2. Cross-section showing structure immediately surrounding axial pipe. × 1. Etched 1 hr. with 20 per cent H_2SO_4 at 60 deg. C.

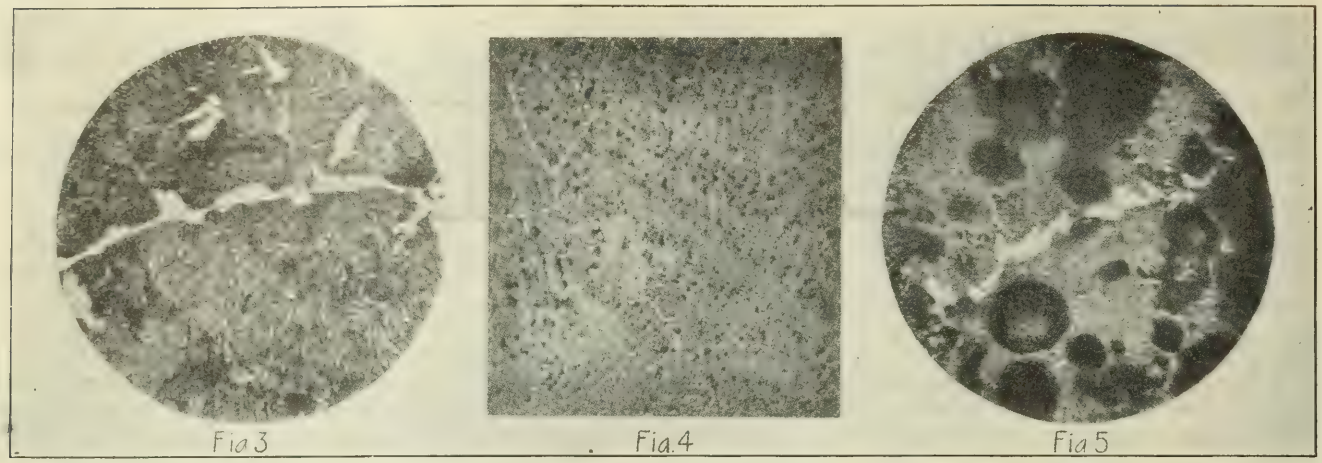

FIG. 3. Free ferrite in ingot, uncontaminated by slag. × 80. Etched in 5 per cent HNO_3 in amyl alcohol.

FIG. 4. Ferrite and dendrite photographed after duplex etching. × 10.

FIG. 5. Part of Fig. 4, magnified 65 diameters.

400 mm. on a side. One of these was cropped somewhat above the bottom of the pipe, and the body of the ingot split along its axis. Figs. 1 and 2 respectively show, at about natural size, the structure surrounding the shrinkage cavity, after etching the polished surface for 1 hr. with 20 per cent sulphuric acid at 60 deg. C. and then slightly polishing the relief with finest emery cloth. Dendritic structure is very clearly exhibited.

Passing over the very interesting change in the metal at the walls of the cavity, the experiments described below will all be made on samples well back into the body of the ingot, and unaffected by any such variation. If such a test piece was highly polished and lightly etched by a 5 per cent nitric acid solution in amyl alcohol, delicate veins of ferrite were seen tracing a network of kernels several millimeters across. The problem now before us is to determine whether there appeared any relationship between form and disposition of dendrites and meshes.

First, it was necessary to show that the ferrite was uncontaminated with slag. I had already determined that granules of slag are sometimes associated with ferrite in certain characteristic forms and positions, which observations I hope to present in detail in a later paper. However, as shown in Fig. 3 (at 80 diameters), the veinlets are free from visible non-metallic inclusions, and consequently their location is independent of flocculated slag, at least.

Duplex Etching

The most evident method of showing how the two structures—that is to say, the free ferrite and the primary dendrites—are disposed each to each was to develop both dendrites and ferrite mesh on the same surface. Since the sulphuric acid attack which develops the fir-tree appearances is the more drastic, it must be used first. Then in order to present a reasonably flat surface for photography after the subsequent nitric attack to develop ferrite, the pitted surface must be repolished, but not heavily enough to plane the surface to the bottom of the depressions defining the primary structure.

After such manipulation, the appearance of a sample at 10 magnifications was photographed as shown in Fig. 4. Examination at once indicates that the veins of mesh-like ferrite do not correspond in any way to elements of the primary crystallization. Thus, one of the larger dendritic aggregations falls entirely in the interior of a large cell in the center of the illustration, so that no vein of ferrite develops on its branches. Only in some cases, as at the bottom of the view, do the veins appear to follow axes of crystalline branches, whereas in many other parts—toward the left and center—the ferrite has a course entirely independent of dendrite branches, cutting them often nearly at right angles, and crossing several cavities en route from branch to branch. This independence of the deeply-dug relief is strikingly shown in Fig. 5, representing a central portion of Fig. 4 magnified to 65 diameters.

This method of etching is open to the objection that a great quantity of free ferrite could exist, ranged along the bottom of the etching pits, and never be developed or seen by the nitric-acid etching. So in order to avoid such a contingency, I utilized the method of making successive photographs of one area. In this procedure, an exposure was first made of a polished surface etched with the nitric-amylic solution, so as to exhibit the ferrite system in its entirety, and a second photograph taken of the same surface after deep etching with hot sulphuric acid, developing the dendritic structure exclusively. Extreme care was used to make the negatives at exactly the same

FIG. 6. Ferrite mesh. Etched in amylic solution of HNO_3. × 3.

FIG. 7. Dendritic structure underlying Fig. 6. Etched in hot H_2SO_4. × 3

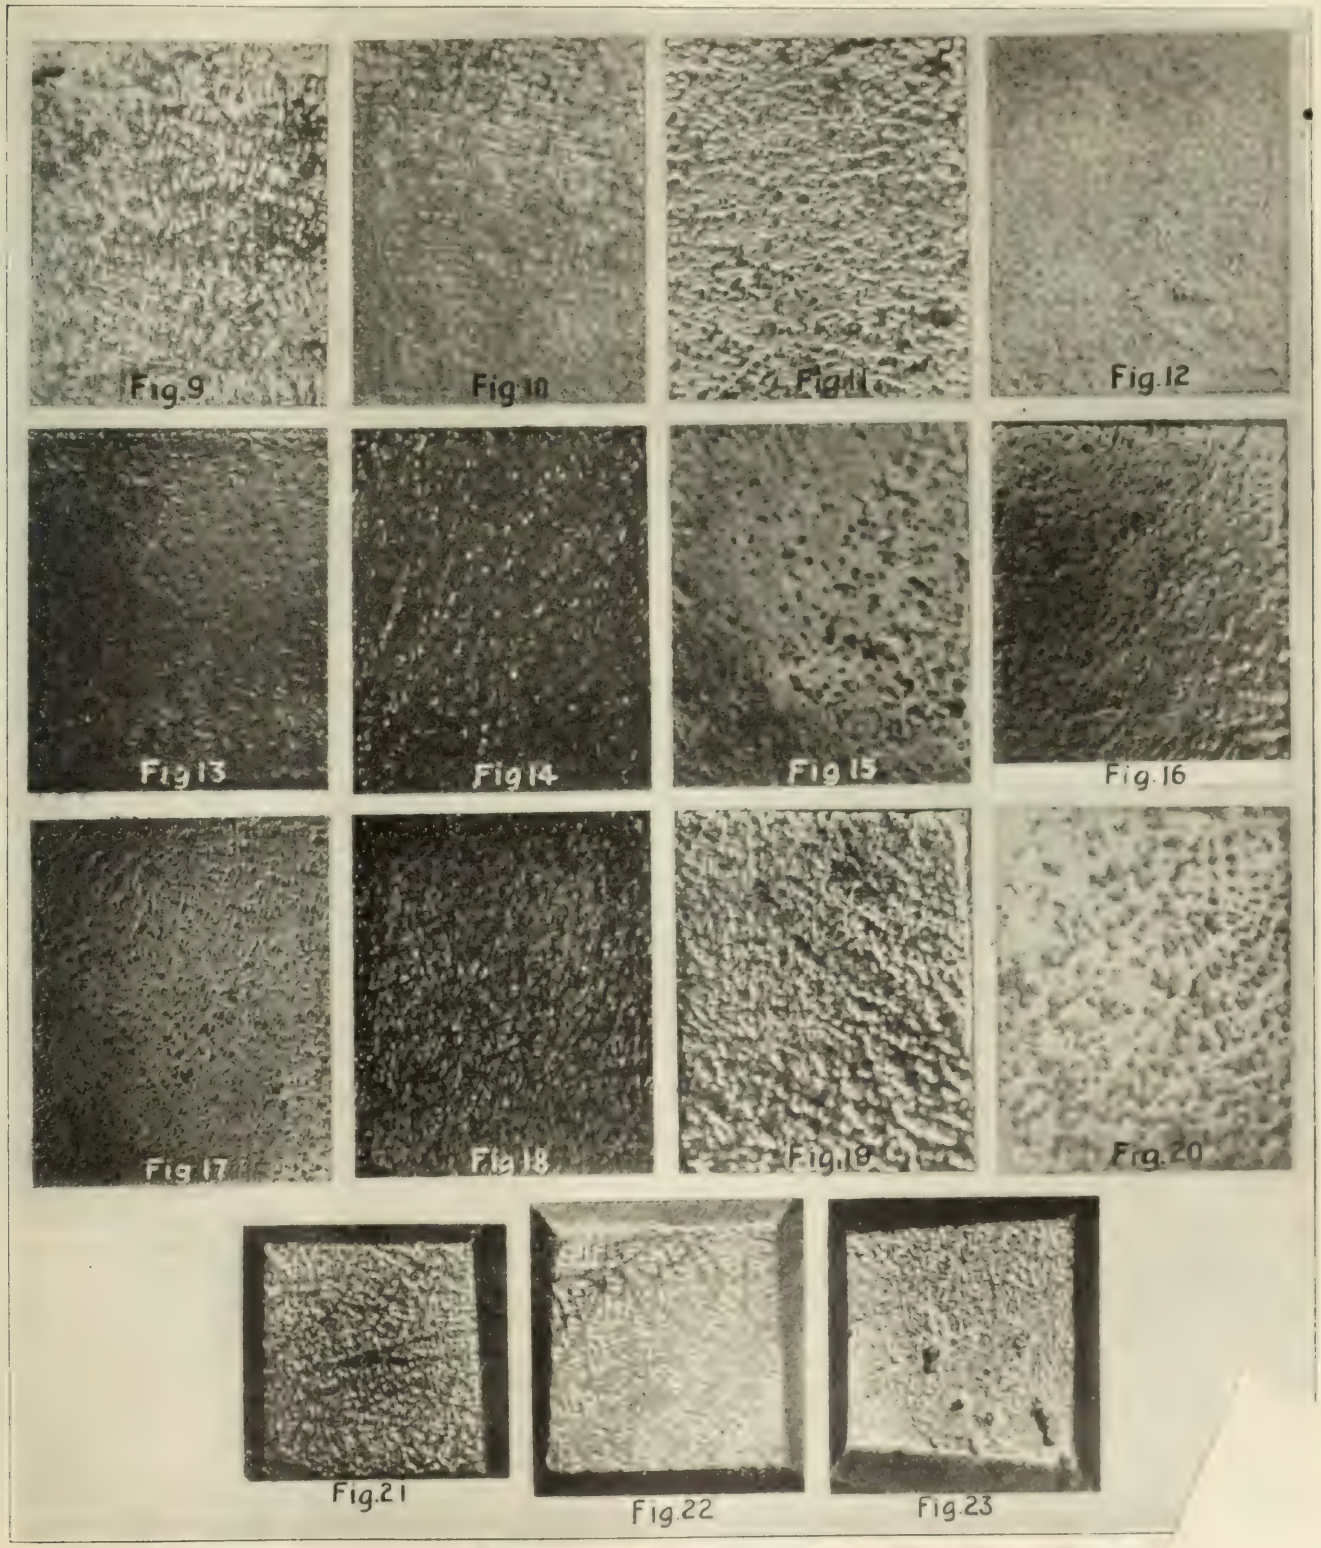
FIG. 8. Negatives of Figs. 6 and 7 superposed in printing frame.

magnification, and of exactly the same field. Then the two negatives were properly superposed in a printing frame, correctly oriented by the use of suitable reference marks, and a single positive made.

Since the glass plates have a considerable thickness, one of the developed films cannot be in close contact with the sensitized paper, and its print will necessarily be somewhat blurred. However, if this one is the negative showing the dendritic system, its print will not suffer, because by its nature it consists of ill-defined elements at best. Consequently a greater deficiency in sharpness of contour does not affect its utility for determining the structural relations we are studying.

In this manner several samples of the ingot were etched and photographed, giving prints similar to those reproduced in Figs. 6, 7 and 8. Fig. 6 shows a surface etched with nitric-amylic solution, Fig. 7 the same area after etching in hot sulphuric, and Fig. 8 is printed from the superimposed negatives.

A study of these and other prints made in the same



FIGS. 9 TO 23. DENDRITIC STRUCTURE DEVELOPED BY DEEP H_2SO_4 ETCHING IN SPECIMENS 1 TO 15
Figs. 9 to 20—Magnified 10 diameters. Figs. 21 to 23—Magnified 3 diameters.

way merely confirms with certainty the observations deduced from Fig. 4, namely, that if in some regions the veins of ferrite appear to accompany the depressed areas separating principal branches (as at the bottom of the figure), there is a much larger number of cases where the veins do not accompany dark depressions, in fact have a course entirely independent of the axes or edges of the limbs. In some of the photographic exposures veinlets of ferrite were occasionally found passing down the ribs of dendrites, but in other prints or even in the same plate, other veinlets favored the depressions between branches. Other ingots of similar steels gave results in every way concordant with these.

For the ingot steels examined, therefore, it seems to be proved that there exists no rigid or constant relation between the reciprocal positions of dendritic elements and ferrite meshwork. Such a fact, if broadly confirmed, would be of greatest importance to metallographers and metallurgists, since the secondary crystallization (i.e., of ferrite or cementite from austenite) is usually regarded as being intimately affected by the system of dendrites, and the position of the ferrite meshwork determined by the difference in carbon concentration, axis to periphery, of the primary austenite. Ziegler[2] and Oberhoffer[3] have indeed advanced the view that accumulations of slag particles have a preponderating effect on the orientation of ferrite mesh; but even this view depends upon the fact that the primary crystallization process determines the location of any segregations of impurities.

Impotence of Single Anneals

To extend the observations it appeared natural to study the variation in relations, ferrite to dendrite, which may be produced by such heat treatments as are known definitely to break up the original ferrite in ingot structure. Such a study might perhaps throw light on the origin of the two crystalline systems, primary and secondary, and by correlating the thermal studies with a careful series of mechanical tests, interesting conclusions might be drawn concerning the specific influence of each structure on the strength, ductility, toughness, fracture and other important physical properties.

Therefore a series of prismatic test pieces about 35 x 35 x 200 mm. in dimension were cut from the ingot first described. Various reheatings were conducted in a small tube furnace, heated electrically by platinum resistance ribbon. A cold specimen was placed in the cold furnace, and current switched on sufficient in amperage to bring the temperature up to the desired point in about 1.5 hr. After remaining at the given heat for the desired time, the sample was either cooled slowly in the furnace (6 hr. to 200 deg. C.) or more rapidly in a wire basket in air. The last three coupons (13, 14 and 15) were given drastic single, double and triple heat treatments, considered in practice most efficacious to transform profoundly the crystalline structure of unworked ingot steel. Table I gives the details. The Brinell number was taken on a machined surface at least 5 mm. below that exposed during heat treatment, so as to avoid any softening due to decarbonization.

The same machined surfaces were then polished and double etched, with a light intermediate polishing, exactly like the procedure described for Fig. 4. Figs. 9 to 20 inclusive show the surfaces of specimens Nos. 1 to 12 inclusive after the deep etching by hot sulphuric acid, and Figs. 24 to 35 their microstructure after a subsequent etching for free ferrite.

As is seen by Figs. 9 to 20 of the etching pits, none of these single heatings, followed by leisurely coolings, has suppressed or sensibly subdivided the dendritic structure, an observation of great interest. Neither has the ferrite meshwork in the samples heated to 700 deg. been destroyed (Figs. 24 to 27), nor has their orientation been changed in any way to one more regularly ordered with the etching pits. This was to be expected, however, since a differential heating and cooling curve taken with Le Chatelier-Saladin apparatus, depicted in Fig. 39, shows that the first transformation point on heating is above 700 deg. C.

Redeposition of Ferrite on Annealing

On the other hand, beginning with the fifth sample (Fig. 28) the heat treatment has caused the carbide in the pearlite kernels to go into solid solution in β or γ iron, and as the temperature increases the ferrite meshes also are absorbed by this austenite. Then on cooling excess ferrite is precipitated into a new meshwork, whose aggregation depends upon the velocity of cooling and, according to many investigators, upon the system of primary crystals. That the size of secondary ferrite mesh is dependent upon velocity of cooling is confirmed by a comparison of Fig. 28 with 29, Fig. 30 with 31, Fig. 32 with 33, and Fig. 34 with 35, each pair of which were reheated in an identical manner, but the even numbered micrographs containing larger pearlite kernels and coarser ferrite shells were cooled much more slowly.

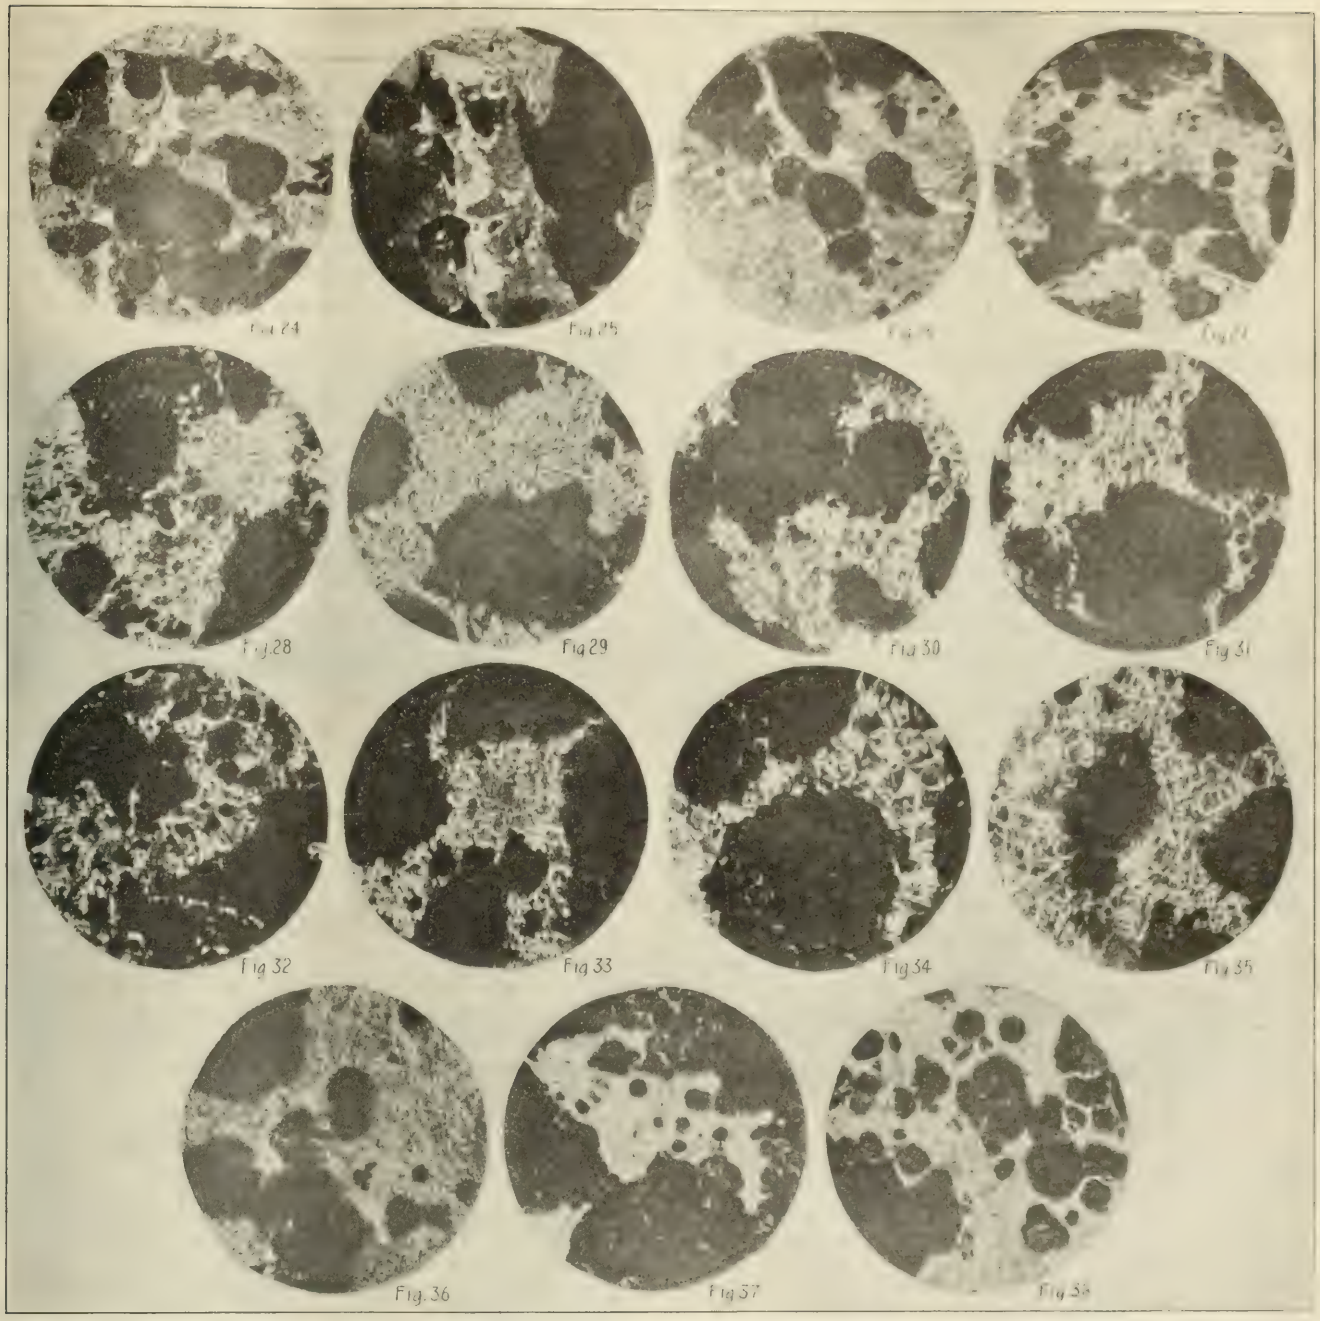
In nickel steels such as the one under examination a very coarse ferrite mesh is especially easily transformed into a very fine network, even by a single reheating followed by a normal cooling.

These well-known facts are mentioned only to call attention to the deduction which can be made from the same micrographs that the dimensions of the elements forming the ferrite mesh depend upon the time and temperature of the precedent heating, as well as upon the velocity of cooling. Comparing micrographs of pairs of samples whose history varies only as to the time at a high heat, it is seen that the ferrite crystals are larger in proportion as the temperature is high and the sustained time is long (Fig. 34). But if we hold with many authorities that this gradual and regular increase in ferrite meshwork is a consequence of a similar increase in the dimensions of the primary crystal constituents in the steel, a corresponding indication should appear in the microstructure of this series of specimens. Examination of the twelve photographs, Figs. 9 to 20 inclusive, shows no indication of such growth in the dendrites developed by hot sulphuric attack.

Unquestionably these two systems of crystals, dendrites and mesh, are morphologically independent during simple reheatings to 900 deg. C. Therefore if ferrite mesh is dependent upon a system of primary crystals, the primary crystals in nickel steels in turn must be independent of the dendrites developed by deep etching. Studies made by superposing photographs as described for Fig. 8 dimly suggest that if there is any such hypothetical interrelation between primary crystals (that is, those which first separate from the cooling liquid) and the fir-tree structure appearing after hot sulphuric acid

[2] "Sur la crystallisation du fer alpha," *Revue de Métallurgie*, 1911, vol. 8, p. 664.

[3] *Z. anorg. Chem.*, vol. 81, p. 156.



FIGS. 24 TO 38. FREE FERRITE CRYSTALS DEVELOPED BY ETCHING SPECIMENS 1 TO 15 RESPECTIVELY IN 5 PER CENT HNO_3 IN AMYL ALCOHOL. × 10

attack, it is at most an "agglomeration" effect, where the different branches of the dendrites may be built up by the union of a large number of minute primary crystals, yet each system seems to be independent of changes and transformations in the other. Such conclusions, if substantiated generally, would modify profoundly the commonly accepted hypotheses connecting segregation of impurities and alloying elements with the mechanism of crystallization during solidification.

Destruction of Dendritic Structure

In order to link up these crystallographic studies with the corresponding mechanical properties, it seemed well to produce if possible a sample void of dendritic structure for use as a basis of comparison. Consequently samples 13, 14 and 15 (Table I) were prepared and photographed. As seen in Figs. 21, 22 and 23, even after the single and double quenching, samples 13 and 14 still possess a dendritic system practically as well defined as any of the others. Only in sample 15, subjected to a triple quench after prolonged heating at very high temperatures, was deep etching unable to develop fir-tree markings.

As could be predicted, the microstructure of these latter specimens (Figs. 36, 37 and 38) does not exhibit any ferrite meshwork at moderate magnifications. Instead, tempering at a heat below the transformation range produces a conglomerate from the solid solution, equalized in carbon content at least by the long sojourn in the austenitic range preceding a drastic quenching.

These simple observations permit one to extend the conclusions already reached in an important direction, and that is that normalizing heat treatments based on diffusing the excess constituent and then preventing its re-segregation by rapid cooling past the critical range are enormously less potent on the dendrite system than

TABLE I.

Specimen No.	Heat Treatment: Heating	Heat Treatment: Cooling	Heat Treatment: Annealing	Brinell Hardness	Macrostructure, Fig.	Microstructure, Fig.
1	1 hr. at 700°	Furnace		179	9	28

15	10 hrs. at 1,190° 11 hrs. at 1,160° 10 hrs. at 1,090°	2 hrs., 25 min. to 800° C. Then quenched in water. 2 hrs. to 800° C. Then quenched in water. 2 hrs. to 800° C. Then quenched in water	2 hrs. at 580°	196	23	46

on the ferrite network, or the crystalline organization which determines its form. Other experiments seem to indicate that one can obtain sensible modifications in form of the dendrites or fir-trees with simple heat treatments, but it is certain that extremely prolonged "heating for diffusion" is necessary to smooth out effectively the local segregations responsible for etching pits ranged along geometric branches.

Mechanical Tests

Returning to the mechanical tests, small Frémont bars shaped like a countersunk rivet (Fig. 41) were cut from each of the fifteen heat-treated specimens. The

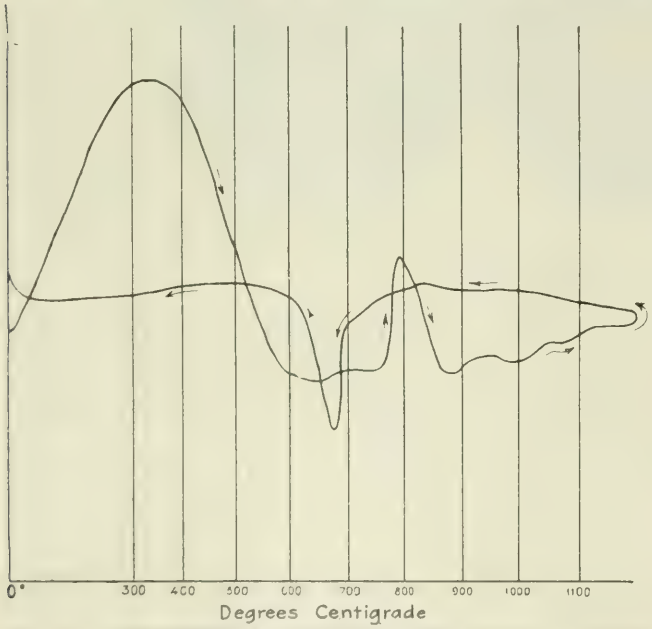

FIG. 39. DIFFERENTIAL HEATING AND COOLING CURVE FOR STEEL UNDER INVESTIGATION

cylindrical part of this little coupon in which rupture will occur is 10 mm. long x 8.2 mm. in diameter. Table II gives the results of the tension tests, and also contains remarks as to the nature of the fracture. Bending tests were also made on the first six specimens, using bars 10 mm. square x 60 mm. long, as listed in Table III. Shock tests in the Frémont impact machine are tabulated in Table IV, using samples 8 x 10 x 80 mm. in dimension, notched on the 8-mm. surface with a semi-cylindrical cut, and the appearance of the fractures given in Fig. 40.

Examination of the test results shows a rough correspondence in certain features to the heat treatments. The latter proceeded from simple to complex by a series of steps, and parallel steps may be discerned in the

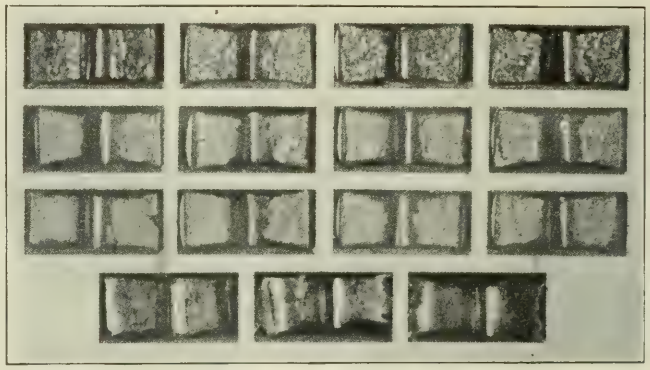

FIG. 40. FRACTURES OBTAINED UNDER IMPACT TEST

structural and mechanical properties. Thus, the dendrite system passes from samples where the heat treatments leave it entirely unaltered to that which produces the most profound transformation possible in practice. Also the character of the fracture, which is always held to be of utmost importance, shows in all three sets of mechanical tests a series of steps from coarsely crystalline or granular to the finest fibrous or silky break. It should therefore be possible to trace some apparent relations between heat treatments, structural constituents and mechanical properties in the unworked nickel steel under study.

Cause of Crystalline Fracture

So-called granules or coarse crystals in the fracture are certainly not essentially due to the development of the fir-tree crystals, but rather are connected very closely with the state of the ferrite meshwork. This is proved by comparing the micrographs, Figs. 9 to 38, with the tabular columns describing the kind of fracture and their appearance as shown in Fig. 40. For gradual stresses (tension), fibrous fractures first appear in sample 5, whose ferrite had hardly been absorbed and the ingot structure therefore but poorly obliterated. From this point on the tension fracture is about the same except for very small variations, until the last three are reached. Normalizing by quenching and tempering produces materially finer fibers in specimens broken under tension.

In the impact test, Table IV and Fig. 40, granular breaks appear in all samples merely reheated, becoming finer as the reheating is the more elevated. Multiple heat treatments (samples 13, 14 and 15) are again able to refine the fracture into a fibrous appearance. However, examination of the micrographs, Figs. 24 to 38, does not show a pronounced variation by steps to correspond to the very pronounced graduations in fracture under impact. For example, sample 6, Fig. 29, has a much finer meshwork than that of sample 11, Fig. 34, yet under impact sample 6 has a fracture fairly de-

scribed as crystalline, and sample 11 as fine crystalline. Apparently, then, in addition to the general effect which ferrite meshwork exerts upon grain size as revealed in fracture, a second unknown influence must be superposed, even though of lesser importance. It seems that this second influence cannot be that of the fir-tree crystals revealed by H_2SO_4 etching, since Figs. 9 to 23 show that the dendritic system remains substantially unmodified. It is not so certain, however, that the various heat treatments, through which the dendrites retain their form and size sensibly unchanged, have not materially changed the absolute concentration of the various elements or compounds (other than cementite) in solid solution with the iron, without dispersing effectively the last parts of the segregations arranged

in semi-geometric pattern which are responsible for the appearance of fir-trees on deep etching. Such partial diffusion obviously would not change the arrangement of the etching pits, and any resulting change in speed of acid attack would be difficult to measure.

More Than One Crystalline System Influences Physical Properties

Further analysis of the mechanical tests yields interesting confirmation of the hypothesis that two distinct systems are superposed in effecting variations in physical properties. For instance, in the tension tests—Table II—the ultimate strength wanders somewhat vaguely between extreme values of 66.5 and 79.16 kg. per sq.mm. with no reference whatever to variations in heat treatments. Brinell hardness as reported in Table I also shows similar unconformity.

On the other hand, the first four samples possessing the original ingot structure act precisely as would be expected from a conglomerate of two different elements of considerable size, yet with one, the ferrite mesh, predominating in influence. Thus, only these four samples were stretched throughout their entire length, "necking" but little at the break, and exhibiting a mottled surface appearance due to so-called "lines of Lüders." The small contractions of area are a natural consequence of this condition. Samples 5 to 12, reheated above the critical range, have other properties varying independently of the condition of the free ferrite. Thus the contractions do not vary over a great

TABLE III. FLEXURE TESTS

No. of Specimen	Maximum Load, Kg.	Deformation at Maximum Load, Mm.	Kind of Fracture	Remarks
1	2,887	2.80	Crystalline	Strained throughout
2	3,174	3.00	Crystalline	Strained throughout
3	3,174	4.55	Crystalline	Deformed only near fracture
4	2,927	4.70	Crystalline	Deformed only near fracture
5	3,160	6.20	Fibrous	Deformation well localized
6	3,512	7.75	Fibrous	Deformation well localized

range, but No. 9, with a much coarser network than No. 6, has a larger contraction, as is even more markedly the case when comparing No. 11 with No. 7. On the other hand, the last three samples, containing no ferrite microcrysts, have the largest contraction.

Fracture in Tension Follows Ingot-Ferrite

In order to determine if possible the exact influence which the fine ferrite meshwork existing in the original ingot structure has upon the course of fracture under tension, a flat specimen of the shape recommended by Frémont and illustrated in Fig. 4 was cut and polished on both sides. This sample not only permitted easy photography, but would exhibit in one specimen the strain-effects varying from moderate forces to those producing rupture. In order to examine simultaneously the lines of Lüders (or deformation figures) and the ferrite network, a longitudinal strip was etched down the axis of the test piece by directing a small rivulet of amylic-nitric reagent across the polished surface, with a result pictured in Fig. 41. Elements of the large ferrite network are thus dimly developed.

After breaking, the piece was again photographed as shown in Fig. 42. If this illustration be examined attentively, paying particular attention to the prolongation of the ferrite veins from the areas where they are developed by acid attack through the areas where they are developed by intense strain, the following facts are apparent:

First, the surface along which total rupture took place, even if the slip was only momentary, corresponds entirely to elements of the large ferrite mesh.

Second, elements of network do not seem to be related

TABLE IV. IMPACT TESTS

No. of Specimen	Total Energy Absorbed Kg.-M.	Kind of Fracture (Fig. 40)
1	12	Coarsely crystalline
2	18	
3	20	
4	20	
5	12	Crystalline
6	12	
7	13	
8	13	
9	31	Fine crystalline
10	32	
11	30	
12	30	
13	32	Short fibers
14	32	Fine long fibers
15	32	

to the lines of Lüders. This is especially evident where the surface of the sample begins to enlarge. Here several ferrite veins appear as a direct prolongation of those developed by acid attack, traversing in many places well developed strain figures, which latter are in fact very much smaller in dimension than the kernels enclosed by ferrite shells.

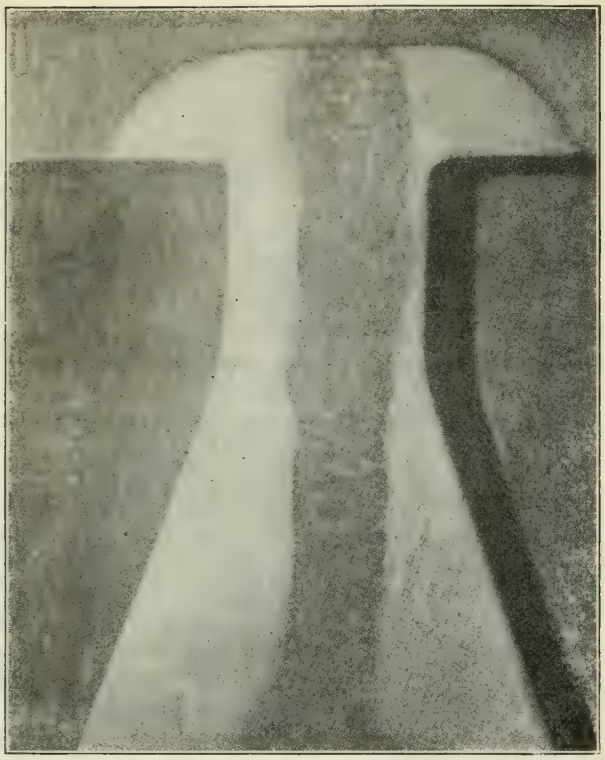

FIG. 41. FLAT TEST BAR, ETCHED PARTIALLY WITH AMYLIC-NITRIC REAGENT

This experiment makes it very clear that the elements of the large ferrite meshwork existing in ingots constitute the surface of lesser resistance along which rupture upon slow stressing takes place considerably before failure at joints of the finer-grained structural system responsible for the deformation figures.

Effect of Reprecipitated Ferrite

Elongations observed at the yield point give a very clear confirmation that in addition to free ferrite a second system of crystallization is increasingly potent in its effect on physical properties. Very large stretches are shown in the first four samples having ingot structure, but the values fall to a minimum immediately the reheating passes the critical range. From this point on, the elongation at yield point increases as the normalizing treatments become more extended, suffering a sudden increase with sample 9, the first having a reheating at 900 deg., but, as before, the values do not seem to have much connection to the amount or disposition of the free ferrite shown in the micrographs. Finally, analogous observations may be made when analyzing the total elongation at rupture. These values, small for the first four samples, increase considerably for the next eight pieces, and still more for the last three, multiple-treated, in fact appearing to be roughly inverse to the size of ferrite mesh.

When testing for static flexure (Table III), the total rupture load does not vary greatly, while the corresponding maximum deformation increases greatly as the heat treatments become more efficacious in eliminating ferrite meshwork. In this case as well, ingot structure is accompanied at failure by mottled surface and non-localized deformation.

Testing under impact brings out the same partial independence of ferrite system. From sample 5 onward there is an undoubted increase in toughness with extended thermal treatment. Beginning with No. 9 (annealed at 900 deg.) there is an especially great resistance to shock, without there being any notable variation in the condition of the free ferrite over that of the four preceding, while from No. 9 on the toughness remains about stationary, even though samples 13, 14 and 15 have extremely fine ferrite. This condition is analogous to that holding for the values of elongation at the elastic limit, an important observation suggesting more than a coincidence and indicating an intimate connection between these two properties. However, it should be remembered that under shock testing the action of a continuous ductile ferrite cement such as exists in the ingot under observation may well be profoundly different than when working under slowly applied loads. Impact may, in fact, cause failure in the kernels rather than failure in the shells.

Conclusions

Such observations establish the following points and define somewhat better the specific function of the ferrite network, previously noted only in general manner as being independent of that of the other co-existing structural systems.

First, in the 2 per cent nickel steel examined, the position and form of ferrite elements is entirely independent of the position and state of the elements of the dendrite system, both when existing totally or partially in the large meshes characteristic of ingot structure, and when the latter is wholly altered.

Second, the elastic behavior of the steel with its original ferrite meshwork is quite unique. The pure iron constitutes a *continuous* plastic system, much more

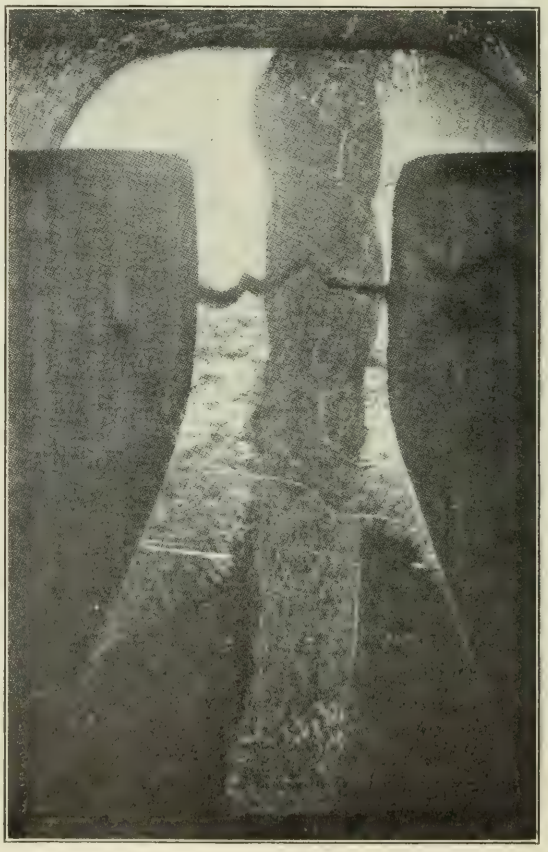

FIG. 42. SAME BAR AFTER FAILURE IN TENSION, SHOWING LÜDERS LINES IN KERNELS AND SLIPPAGE ALONG THE FERRITE SHELLS

easily deformed under gradual stress than the elements of the other structural systems superposed upon it. Under load the total resistance of such ingot metal is determined primarily by the strength of the meshwork, and the elastic properties of such ingot metal conform to those of metals containing a continuous plastic cement binding together kernels of greater toughness and ductility.

Third, once the ferrite meshes have been absorbed in austenite on reheating, it reprecipitates in discrete particles (as has been shown in my previous paper)[4] corresponding more nearly to its own crystalline habit, and simulating a meshwork but in reality remaining essentially discontinuous. In this case the fine and compact elements of the superposed system are more or less continuous. Hence the now isolated ferrite crystallites no longer carry the totality of stress nor exercise a major influence by virtue of their plastic nature, a fact immediately reflected in the physical tests the moment the steel has been annealed above the transformation range. Appearance of fracture, ductility, and toughness immediately show a sharp discontinuity, and thereafter vary with the degree of "normalizing heat treatment" rather than the amount of free ferrite or its state of aggregation.

Proper Heat Treatment Makes Cast Nickel Steel Equal to Best Forgings

Fourth, once these large ferrite shells are destroyed, even heat treatments which allow considerable accumulation of crystalline ferrite in roughly arranged meshwork do not produce corresponding variation in the fracture or other physical properties developed in tension, bending or impact, an indication that they have not yet become truly continuous. Unexceptionably ductile, strong and tough steel with a fine fibrous fracture is obtained from unworked metal only by drastic multiple heat treatments, a conclusion evidently of the highest practical importance in the making of shock-resistant castings of this alloy, and substantiated in everyday manufacture of such important pieces as elements of gun mountings. Many illustrations of physical tests of such pieces are given in the author's book mentioned at the outset of this article.

Fifth, the fracture, ductility and toughness vary consistently with variation in heat treatment, when samples free of ingot structure ferrite are considered. These physical properties do not vary consistently with the microscopic appearance of the ferrite, but appear rather to depend upon the super-position of one or more additional systems of structural elements endowed with characteristic critical intervals. The chief added influence appears to me, if only by the process of exclusion, to be related in some way to the original crystallization of the ingots, and probably is due to improvement of the pearlite ground mass by the gradual diffusion during drastic reheating of those small heterogeneities in the dendrites which are responsible for the etching pits arranged in fir-tree form.

Sixth, a correct explanation of the genesis and transformation of the ferrite system in hypo-eutectoid steels cannot be one involving a close relation to the dendritic system of primary solidification. It must at least be admitted that the elements of the dendritic system are individual crystals resulting from colonies of crystals of secondary origin.

Montan Wax

By Clarence J. West

Bad as our own fuel troubles have been of late, those of England have been worse. The effort to find relief has led to extremely interesting developments. Of special significance are the achievements in furthering the chemical values obtainable in connection with the use of fuel.
